- Some new coding is introduced in the difference GDX file. Namely a new dimension is added to the parameters being compared which can contain 4 entries
 - dif1 indicates that the entry occurs in both files and shows the value found in the first file.
 - dif2 indicates that the entry occurs in both files and shows the value found in the second file.
 - ins1 indicates that the entry only occurs in the first files and shows the value found.
 - ins2 indicates that the entry only occurs in the second file and shows the value found.
- Only named items with the same name, type and dimension will be compared in the `difffile.gdx` output. Named items that are new or are deleted will only appear in the standard output summary report

See more [Examples](#) on inspecting contents with [GDXDIFF](#).

4.46.2 Writing a GDX file

Writing of GDX files in a GAMS model can be done during the compile phase or the execution phase. A GDX file can also be written after compilation and execution.

4.46.2.1 Compile Phase

During compilation, we can use a group of [Dollar Control Options](#) to write data to a GDX file. Writing during the compilation phase also allows us to define the elements of a set and the subsequent use of such a set as a domain. The following [Dollar Control Options](#) are available for writing data to a GDX file into GAMS during compilation of a GAMS model:

- [\\$gdxout](#)
- [\\$unload](#)

4.46.2.1.1 \$gdxout The [\\$gdxout](#) command is used in a sequence either to unload specified items to a GDX file or to close the specified GDX file. The statement with [\\$gdxout](#) can be used in one of the following forms:

```
$gdxout file_name
$gdxout
```

where:

Parameter(s)	Description
file_name	Specify the name of the GDX file (with or without the extension <code>.gdx</code> ; written to from the current working directory)
	(no file_name) closes the GDX file

See [Example 1 - Writing a GDX file](#) and `[CompTimeWriteTransportGDX]` for examples on how to use [\\$gdxout](#).

4.46.2.1.2 \$unload The [\\$unload](#) command unloads specified items to the GDX file. The statement containing [\\$unload](#) is preceded and succeeded by the [\\$gdxout](#) statements where

- the preceding [\\$gdxout](#) specifies the GDX file name and opens the file.
- the succeeding [\\$gdxout](#) closes the GDX file.

The statement with [\\$unload](#) command can be used in one of the following forms:

```
$unload
$unload id1 id2 ... idn
$unload id1=gdxid1 id2=gdxid2 ... idn=gdxidn
```

where:

Parameter(s)	Description
	(no identifiers) Write all symbols to the gdx file
id1 id2 ... idn	Write GAMS symbols id1, id2, ..., idn to the GDX file
id1=gdxid1 id2=gdxid2 ... idn=gdxidn	Write GAMS symbols id1, id2, ..., idn with corresponding names gdxid1, gdxid2, ..., gdxidn into the GDX file

See [Example 1 - Writing a GDX file](#) and `[unload1]` - `[unload9]` for examples on how to use `$unload`. See also `[CompTimeWriteTransportGDX]` example.

4.46.2.2 Execution Phase

When writing data to a GDX file during execution phase the data in the GDX file will be the data present in the GDX file at the time that the statement is executed. The results of all prior calculations and the most recent solve for any model will be reflected. The statements to read data from a GDX file during execution phase are

- [execute_unload](#)
- [execute_unloaddi](#)
- [execute_unloadidx](#)
- [savepoint](#)

4.46.2.2.1 execute_unload, execute_unloaddi, and execute_unloadidx The `execute_unload` statement replaces an existing file with that name; it does not add symbols to or replace symbols in an existing GDX file. Without specifying any identifier, all sets, parameters, variables and equations will be written to the GDX file.

The `execute_unloaddi` statement replaces an existing file with that name; it does not add symbols to or replace symbols in an existing GDX file similar to [execute_unload](#), but also writes the domains of all unloaded symbols to the same file.

The `execute_unloadidx` statement requires that each symbol written is a parameter; each parameter must have a domain specified for each index position. These domains have the requirement that they are formed using an integer sequence for the UELs that starts at 1 (one). The domain names are changed to indicate the size of each domain. This information is used when reading the data back from the GDX file using `$LoadIDX` during compilation. Using the special domain names, the UELs for the domains can be recovered without writing the domains to the GDX file; see example below.

The statement with `execute_unload` can be used in one of the following forms:

```
execute_unload 'file_name' , id1, id2, ..., idn ;
execute_unload 'file_name' , id1=gdxid1, id2=gdxid2, ... ;
execute_unload 'file_name' , setid=* ;
```

The statement with `execute_unloaddi` can be used in one of the following forms:

```
execute_unloaddi 'file_name' , id1, id2, ..., idn ;
execute_unloaddi 'file_name' , id1=gdxid1, id2=gdxid2, ... ;
execute_unloaddi 'file_name' , setid=* ;
```

The statement with `execute_unloadidx` can be used in one of the following forms:

```
execute_unloadidx 'file_name' , id1, id2, ..., idn ;
execute_unloadidx 'file_name' , id1=gdxid1, id2=gdxid2, ... ;
execute_unloadidx 'file_name' , setid=* ;
```

where

Parameter(s)	Description
file_name	Specify the name of the GDX file (with or without the extension .gdx; written to from the current working directory)
id1, id2, ..., idn	Write GAMS symbols id1, id2, ..., idn into the GDX file
id1=gdxid1, id2=gdxid2	Write GAMS symbols id1, id2 with corresponding names gdxid1, gdxid2 into the GDX file

Note

- when only `file_name` is specified without other parameters all GAMS Symbols will be written into the GDX file `file_name`.
- The GAMS option `gdxUEls` controls which UELs are registered in `file_name`. With option `gdxUEls = squeezed`; (default) only the UELs that are required by the exported symbols are registered while all known UELs are registered if we set option `gdxUEls = full`; . See also [\[unload10\]](#).

See [Example 2 - Writing a GDX file](#) and [\[qp1x\]](#) on how to use `execute_unload`. See [\[unload10\]](#) on how to use `execute_unloadi`. See [Example 3 - Writing a GDX file](#) on how to use `execute_unloadidx`.

4.46.2.2.2 Savepoint A GDX file containing the marginals and levels for all variables and equations at the end of a solve will be created with the [command line parameter](#), [model attribute](#) or [option statement](#) `Savepoint`. One can save the solution information from the last solve or from every solve. The points that are saved can be used to provide an advanced basis, integer program starting point or NLP starting point.

The basic [command line](#) form is:

```
gams mymodelname Savepoint=number
```

the [model attribute](#) form is

```
modelname.savepoint=number;
```

and the [option statement](#) form is

```
option savepoint=number
```

where

- when number equals 1 a point gdx file is saved from the last solve in the GAMS model and the file name will be `modelname.p.gdx` where model name is the name of the model identified in the solve statement.
- when number equals 2 a point gdx file is saved from the every solve in the GAMS model and the file name will be `modelname.pnn.gdx` where model name is the name of the model identified in the solve statement and nn is the internal number of the solve. Thus if 10 solves occur one will get 10 files named `modelname.p1.gdx` through `modelname.p10.gdx`.

The following example:

```
model firm / all /;
firm.savepoint=1;;
solve firm using LP maximizing objfun;
```

saved a point gdx file `firm_p.gdx`.

and:

```
model transport /all/ ;
option savepoint=2;
set newseattle /s1,s2/;
parameter datador(newseattle) /s1 350, s2 450/;
```

```
loop(newseattle,
    a("seattle")=datador(newseattle);
    Solve transport using lp minimizing z ;
);
Display x.l, x.m ;
```

saved two point gdx files `transport_p1.gdx` and `transport_p2.gdx`.

Note

- the GDX point file contains numerical records for all variables and equations giving just their levels and marginals. In a non point GDX file information on bounds and scales are also present, if defined.

4.46.2.3 Example 1 - Writing a GDX file

This example has modified the file `transport.gms` from [TRANSPORT] by adding the following statements after the last line.

```
...[TRANSPORT]...
```

```
d(i,j)=d(i,j)*10;
```

```
$gdxout tran
$unload i j
$unload d
$unload f
$unload b=dem a=sup
$gdxout
```

This example creates the GDX file `tran.gdx` containing the data for the sets `i` and `j` as well as the parameters `d`, `f`, `a` and `b` during the compile time, when `a` and `b` have been renamed in the GDX file to `dem` and `sup`. Also note the parameter `d` will not have been multiplied by 10 but rather take on their compile time value.

An `$unload` statement above can specify more than one symbol to be writtten to a GDX file and the similar result could also be accomplished using:

```
...[TRANSPORT]...
```

```
d(i,j)=d(i,j)*10;
```

```
$gdxout tran
$unload i j d f b=dem a=sup
$gdxout
```

4.46.2.4 Example 2 - Writing a GDX file

This example has modified from the file `transport.gms` (from [TRANSPORT]) by adding the following statement right after the solve statement.

```
...[TRANSPORT]...
```

```
Solve transport using LP minimizing Z;  
execute_unload 'results.gdx', i, j, z, x;
```

After solving the model, the sets `i` and `j` and the variables `z` and `x` with all the data available after the solve.

4.46.2.5 Example 3 - Writing a GDX file

This example shows the use of the indexed write and read data during execution phase:

```
Set I /1*100/,  
    J /1*50 /;  
parameter A(I,J) /1.1=11, 1.9=19, 10.1=101/;  
  
execute_unloadidx 'data.gdx', A;
```

Viewing the file `data.gdx` in the gamside shows the modified domain information:

To read from `data.gdx`, we use the indexed read:

```
Set I,J;  
parameter A(I,J);  
* load the data  
$gdxin data.gdx  
$loadidx A  
$gdxin  
* write all symbols so we can inspect in the gamside  
$gdxout test.gdx  
$unload  
$gdxout  
  
execute_unloadidx 'data.gdx', A;
```

Viewing the file `test.gdx` in the gamside shows that the domains have been populated:

4.46.2.6 Writing a GDX file after compilation or execution

A GDX file containing all data items resident at the end of the run of a GAMS code can be created using the [gdx](#) command line option either via [GAMS call](#) at the command line or via the command line parameter box in the IDE. This will cause all sets, parameters, variables and equations to be written to the GDX file.

For example:

```
gams mymodelname gdx=gdxfile_name
```

Or

```
gams mymodelname action=c gdx=gdxfile_name
```

where

- `mymodelname` specifies the name of the GAMS file
- `gdxfile_name` gives the file name and possible path where the GDX file is to be retained. When no path is specified the default directory is the current working directory or project directory in the IDE as seen below.
- `action=c` indicates request to write a GDX file after compilation only
- setting GDX to the string "default" (ie `gdx=default`) causes GAMS to create a GDX file with the GAMS file root name and a GDX extension. Thus

```
gams trnsport gdx=default
```

will cause GAMS to write the gdx file `trnsport.gdx`.

When the IDE is used, the GDX file creation is invoked by an entry in the upper right hand corner of the IDE screen as illustrated below:

Note

- When this option is used the GDX file is created just at the end of the GAMS execution so the data written will contain the current values for all sets, parameters, variables and equations that are on hand at the end of the GAMS job.
- The GDX data for the variables and equations contains the levels, marginals, lower bounds, upper bounds and scales for each item.
- This yields a file that may be automatically opened in the IDE by doing a mouse click on the highlighted line in the IDE process window.

Using the `gdx` command line parameter when running the model using the IDE, the process window will show the `gdxfile_name` in blue indicating that the file can be opened using a double-click with the mouse. See also [Inspecting contents with IDE](#).

4.46.3 General notes on GDX files

There are several things worth noting about GDX files:

- When working with GDX only one GDX file can be open at a time.
- When reading data from a GDX file, the symbol to be read must be declared before the reading statement appears.
- When the GDX file to be written has the same name as an existing GDX file the existing file will be overwritten. The resultant file will only contain the new data; there is no merge or append option.
- The [\\$unload](#) command to write a GDX during compile time using the will only write out data defined in the compilation at the point where the command appears. No results of any solves or calculations done within the current GAMS program will be reported with ‘[\\$unload](#)’. This is not true when using the [execute_unload](#) or [execute_unloaddi](#) commands.
- Both [execute_unload](#) and [execute_unloaddi](#) will write out data defined in the execution sequence at the point where the command appears. The results of the most recent solve command and any parameter calculations occurring before the GDX write will be reported.
- Any subsequent [execute_unload](#) or [execute_unloaddi](#) to a GDX file written earlier will totally overwrite that file so care must be taken to write all wanted information in the last appearing [execute_unload](#) or [execute_unloaddi](#)
- A command line GDX write using the `gdx=file_name` command line parameter will write out data defined at the end of the execution sequence. The results of the most recent solve and any parameter calculations will be reported.
- When loading data note that domain checking will not be enforced so that when items are resident in the GDX file for set elements not present in the current file these items will be ignored. GAMS will not generate any message to tell you items are ignored.
- Option [Savepoint](#) and [execute_Loadpoint](#) provide a GDX way of saving and loading a basis.
- The contents as they differ between GDX files can be examined with [GDXMERGE](#) or [GDXDIFF](#)/
- GDX files as of version 22.3 are written in compressed form unless the environment variable GDXCOMPRESS is set to zero.
- Starting with GAMS version 22.3, gdx files can be written in a compressed format unless the environment variable GDXCOMPRESS is set to zero. A value of 1 indicates compression.
- Compressed GDX files are not readable by older GAMS versions but the utility `gdxcopy` allows one to transform to older versions.
- GDX files from different GAMS version can possibly be incompatible due to compression among other changes. A current GAMS system can read all older GDX file formats. GDX files can be converted to a compressed format or an older format using [GDXCOPY](#).
- Users can also write their own programs accessing data in a GDX file via the [expert-level GDX API](#) using `gdxdcplib` library. The interface and usage for this library is described in a separate document; see [gdxioapi.chm](#) or [gdxioapi.pdf](#).

4.46.4 GAMS Data eXchange Tools

A number of GDX based tools and GDX related tools are included in GAMS distribution and maintained by GAMS. See also [Tools Manuals](#).

- The [data exchange tools](#) provide functionality to exchange data between GAMS and other data sources.
- The [GDX service tools](#) operate directly on GDX containers.
- Some of [Data transformation tools](#) perform very specific data transformation tasks that are either awkward or inefficient to implement in GAMS directly.

Some utilities are available only on specific platform. See [Supported Platforms](#) for more details.

4.47 Extended Mathematical Programming (EMP)

Extended Mathematical Programming (EMP) is an extension to algebraic modeling languages that facilitates the automatic reformulation of new model types as models in more established mathematical programming classes, allowing them to be solved by mature solver algorithms. A number of important problem classes can be solved, e.g. Nash games and equilibria, bilevel programs, Disjunctive Programs and Stochastic Programs. EMP is independent of the modeling language used but is currently implemented only in GAMS. The new types of problems modeled with EMP are reformulated, using the GAMS solver JAMS, as well established types of problems, and the reformulated models are passed to a suitable GAMS solver to be solved.

EMP models are defined by information taken from two places: the traditional model definition and a text file containing annotations or additional information. The usual model definition contains variables, constraints and/or functions, and perhaps also an objective or matching information. Additional annotations to specify relationships that don't fit within this traditional definition are taken from the EMP info file. For example, the constraints for two optimizing agents in a competitive game can be specified with traditional algebra, while the structure (who owns what variables and constraints) can be specified in the info file. Together, this allows large, complex models to be specified in a convenient, precise, and flexible way.

This chapter is organized as follows.

- [EMP Annotations: the EMP Info File](#)
- [Soft Constraints](#)
- [Variational Inequalities \(VI\)](#)
- [Quasi-Variational Inequalities \(QVI\)](#)
- [Equilibrium Problems](#)
- [Embedded Complementarity Systems](#)
- [Equilibrium Problems with Shared Constraints](#)
- [Equilibrium Problems with Shared Variables](#)
- [Bilevel Programs](#)
- [Disjunctive Programming](#)
- [Stochastic Programming](#)
- [EMP Keywords](#)

Note

- At the end of each section we present and discuss the general syntax that EMP provides to write the annotations for that particular problem type. We use the usual GAMS syntax symbols: `[ ]` (the enclosed construct is optional), `{ }` (the enclosed construct may be repeated zero or more times) and `|` (exclusive OR).
- Many EMP model examples are available in the **GAMS EMP Library**.

4.47.1 EMP Annotations: the EMP Info File

EMP models are defined by both the usual content of a GAMS model and annotations found in a simple text file named `emp.info` (aka the EMP info file). It is often most convenient to create this file via the [GAMS put writing facility](#). The annotations primarily serve to *define* the model (e.g. to specify that a variable `u` is really the dual multiplier for a constraint `g`) but can also specify how a solver should process the model. The annotations make use of [EMP keywords](#) to do this.

A simple example will serve as illustration. Consider the following NLP:

$$\begin{array}{ll} \text{Min}_{x,y,z} & -3x + xy \\ \text{s.t.} & x + y \leq 1 \\ & x + y - z = 2 \\ & x, y \geq 0 \end{array} \quad (1)$$

We will use EMP annotations to automatically generate the first order conditions (KKT conditions) of this NLP and thus reformulate the NLP as an MCP:

```
Variables          f, z;
Positive Variables x, y;

Equations g, h, defobj;

g..      x + y =l= 1;
h..      x + y - z =e= 2;
defobj.. f =e= -3*x + x*y;

Model comp / defobj, g, h /;

File info / '%emp.info%' /;
putclose info / 'modeltype mcp';

solve comp using EMP minimizing f;
```

Observe that the model is defined in the usual way and the file `emp.info` contains just one line: `modeltype mcp`. The [EMP keyword](#) `modeltype` indicates that the value following the keyword is the model type to be used for the reformulation. In this example the model type is `mcp`. Here this specification is required: the sole point of our EMP annotations is to generate an MCP and not (as is usually the case) to define the model. Usually, the model algebra and annotations together imply the type of the reformulated model and so no `modeltype` specification is required or wanted. Finally, note that the model type in the solve statement is `EMP`: this is typical.

The solver JAMS implements the EMP framework. It processes the model and the annotations, automatically reformulates the original EMP model as a model of a different (more easily solved) type, passes the reformulated model on to an appropriate subsolver, and maps the resulting solution back into the original problem space.

In case users wish to inspect the (scalar) reformulated model, the JAMS option `FileName` may be used to specify the name of the file containing this model. Adding the following lines *before* the solve statement in the GAMS code above will cause the MCP reformulation to be saved in the file `myReform.gms`.

```
File empopt / 'jams.opt' /;
comp.optfile = 1;
putclose empopt / 'FileName myReform.gms';
```

The listing file will contain some additional information - the *EMP Summary* - as part of the output for each EMP model solved. We provide details on the EMP summary for each reformulation that we discuss below.

4.47.2 Soft Constraints

In many cases modelers wish to relax certain constraints: violation of these constraints is allowed but is associated with a well-defined penalty. The constraints that are allowed to be violated are called *soft constraints* and the constraints that continue to hold are called *hard constraints*.

In this section we present a [mathematical formulation](#) of soft constraints, give an [example](#) of how soft constraints can be modeled with GAMS EMP and introduce the [EMP annotations specific to soft constraints](#).

4.47.2.1 Soft Constraints: Mathematical Formulation

A general formulation of a constrained minimization problem is:

$$\begin{array}{ll} \text{Min}_{x \in \mathbb{R}^n} & f(x) \\ \text{s.t.} & c_i(x) \leq 0, \quad \forall i \in \mathcal{I}, \end{array} \quad (2)$$

where f and the functions c_i are smooth, real-valued functions on a subset of $\mathbb{R}^n$ and $\mathcal{I}$ is a finite set of indices. Note that in this problem all feasible solutions must satisfy all constraints c_i .

Now assume that some constraints are allowed to be violated (i.e. made soft), while the remaining constraints continue to hold for all feasible solutions. The soft constraints are associated with a *penalty function* that is added to the objective function. Since we have a minimization problem, the effect will be a balance or compromise between competing goals: minimizing the objective and minimizing the penalty functions.

Note

The penalty terms for soft constraints are *added* to the objective function in a minimization problem and *subtracted* in a maximization problem.

Let $\mathcal{L} \in \mathcal{I}$ be the set of indices for the soft constraints: this implies $\mathcal{M} := \mathcal{I} \setminus \mathcal{L}$ is the index set for the hard constraints. Problem (2) becomes:

$$\begin{array}{ll} \text{Min}_{x \in \mathbb{R}^n} & f(x) + \sum_{i \in \mathcal{L}} w_i g_i(c_i(x)) \\ \text{s.t.} & c_i(x) \leq 0, \quad \forall i \in \mathcal{M}, \end{array} \quad (3)$$

where the penalty functions g_i are real-valued functions of $c_i(x)$, $i \in \mathcal{L}$. As we will see later, EMP has implementations of the following penalty functions: absolute value, least squares, and the maximum of a term and zero. Further, w_i is a multiplier associated with each penalty term, also called the *weight*. The weights facilitate prioritizing soft constraints: the weight of more important constraints will be greater than the weight of lesser constraints.

4.47.2.2 Soft Constraints with EMP: A Simple Example

The following simple example is adapted from the JAMS solver manual:

$$\begin{array}{ll}
 \text{Min}_{x_1, x_2} & -x_1^2 \\
 \text{s.t.} & \log(x_1) = 1 \\
 & x_2^2 \geq 2 \\
 & 3x_1 + x_2 \leq 5 \\
 & x_1, x_2 \geq 0
 \end{array} \tag{4}$$

This problem can be formulated in GAMS as follows:

```

Positive Variables x1, x2;
Variables          obj;

Equations f0 "objective function", f1, f2, f3;

f0..  obj          =e= -sqr(x1);
f1..  log(x1)      =e= 1;
f2..  sqr(x2)      =g= 2;
f3..  3*x1 + x2    =l= 5;

Model m /all/;

x1.l = 1; x2.l = 1;

solve m using NLP min obj;

```

Note that this problem has no feasible solution. Thus we choose to relax the first two constraints by adding a penalty for their violation to the objective function. We also weight the relative importance or priority of the objective and the violations of these two constraints by introducing weights to go with these penalty functions. The resulting problem reads as follows:

$$\begin{array}{ll}
 \text{Min}_{x_1, x_2} & -x_1^2 + 5 \|\log(x_1) - 1\|^2 + 2 \max(x_2^2 - 2, 0) \\
 \text{s.t.} & 3x_1 + x_2 \leq 5 \\
 & x_1, x_2 \geq 0
 \end{array} \tag{5}$$

Note that the first constraint is replaced by a least squares penalty of $(\log(x_1) - 1)$ with a weight of 5 and the second constraint by the penalty term $\max(x_2^2 - 2, 0)$ with a weight of 2. However, the "max" penalty makes the objective function non-smooth. To rectify this, we implement the "max" penalty by introducing a new variable v that, due to its bounds and the direction of optimization, will take the value $\max(x_2^2 - 2, 0)$ at the solution. The result is:

$$\begin{array}{ll}
 \text{Min}_{x_1, x_2, v} & -x_1^2 + 5 \|\log(x_1) - 1\|^2 + 2v \\
 \text{s.t.} & 3x_1 + x_2 \leq 5 \\
 & x_1, x_2 \geq 0 \\
 & v \geq x_2^2 - 2 \\
 & v \geq 0
 \end{array} \tag{6}$$

This reformulation could of course be implemented directly in GAMS using standard GAMS syntax, but the EMP solution is easier to create and maintain, to read and understand, and to scale upwards as problem size and complexity increase. For the latter, we can simply add the following [EMP annotations](#) and updated solve statement (to specify solution as an EMP) to the GAMS code [above](#):

```

File soft / '%emp.info%' /;
put soft;
$onput
adjustequ
f1 sqr 5
f2 maxz 2
$offput
putclose;
solve m using EMP min obj;

```

Note that the [EMP annotations](#) contain three lines: the first line, containing the [EMP keyword](#) `adjustequ`, indicates that the lines that follow specify soft constraints, i.e. equations to be converted to penalty terms; the second line specifies the name of the first soft constraint `f1`, the penalty function to use, and - optionally - the weight; and similarly the third line specifies the name of the second soft constraint `f2`, the penalty function to use, and the weight.

The solver JAMS will use the information in the EMP annotations to automatically reformulate problem (4) as problem (6) and pass it along to an NLP subsolver. The [EMP Summary](#) produced by JAMS will contain the following line:

```

--- EMP Summary
...
Adjusted Constraint = 2
...

```

This output reflects that indeed two constraints were "adjusted", i.e. converted to penalty terms in the objective function.

4.47.2.3 EMP Syntax for Soft Constraints

The EMP framework provides the following general syntax to specify constraints that are converted to soft constraints:

```

AdjustEqu equ abs|sqr|maxz {weight}
           {equ abs|sqr|maxz {weight}}

```

The [EMP keyword](#) `AdjustEqu` indicates that the lines that follow specify equations that are "adjusted": they are moved from constraints to penalty terms in the objective function. `Equ` is the name of the equation to penalize, while the three [EMP keywords](#) that follow indicate the penalty function to use. If not specified, the weight used defaults to 1. For an example, see [above](#) or the model `[SIMPENLP]` in the GAMS EMP Model Library.

4.47.3 Variational Inequalities (VI)

Variational inequalities provide a general mathematical framework for many problems arising in optimization. For example, constrained optimization problems like LP and NLP are special cases of VI, and systems of equations and complementarity problems can be cast as VI. Thus VI problems have many applications, including those in transportation networks, signal processing, regression analysis, and game theory.

In this section we present a [mathematical formulation](#) of VI, give an [example](#) of how VI can be modeled with GAMS EMP, and introduce the [EMP annotations specific to VI](#). Note that to fully and properly understand some of this section, the [introduction to MCP](#) provides a useful background.

4.47.3.1 Variational Inequalities: Mathematical Formulation

For a given continuous function $F : \mathbb{R}^n \rightarrow \mathbb{R}^n$ and a fixed closed convex set $K \subset \mathbb{R}^n$ the variational inequality problem $VI(F, K)$ is to find a point $x^* \in K$ such that:

$$\langle F(x^*), (x - x^*) \rangle \geq 0, \quad \forall x \in K, \quad (7)$$

where $\langle \cdot, \cdot \rangle$ denotes the usual inner product.

Observe that the VI generalizes many problem classes:

- If $F(x) = 0$ and $K \equiv \mathbb{R}^n$, the VI is a system of nonlinear equations.
- If $F(x) = \nabla f(x)$, the VI is a convex optimization problem.
- If $F(x) = \nabla f(x)$ and $K = \{x \mid Ax = b, Hx \leq h\}$, the VI is an [NLP](#).
- If $F(x) = \nabla f(x) = p$ and $K = \{x \mid Ax = b, Hx \leq h\}$, the VI is an [LP](#).
- If the feasible region is a box $B = \{x \in \mathbb{R}^n \mid l_i \leq x_i \leq u_i, \text{ for } i = 1, \dots, n\}$, with $l_i \leq u_i$, $l_i \in \mathbb{R} \cup \{-\infty\}$ and $u_i \in \mathbb{R} \cup \{\infty\}$, the VI is an [MCP](#), where $x^* \in B$ is a solution of the respective MCP if for each $i = 1, \dots, n$ one of the following conditions holds:

$$\begin{aligned} F_i(x^*) &= 0 & \text{and} & & l_i &\leq x_i^* \leq u_i, \\ F_i(x^*) &> 0 & \text{and} & & x_i^* &= l_i, \\ F_i(x^*) &< 0 & \text{and} & & x_i^* &= u_i. \end{aligned} \quad (4.18)$$

Note that the set K is frequently defined in the following way:

$$K = \{x \mid x \geq 0, h(x) \geq 0\}. \quad (8)$$

Further, note that the $VI(F, K)$ represents a wider range of problems than classical optimization whenever $F(x) \neq \nabla f(x)$ for some objective function f (or equivalently, the Jacobian of F is not symmetric). For example, problems that can be cast as VI include (generalized) Nash games and Nash equilibrium problems, systems of equations, complementarity problems, and fixed-point problems.

4.47.3.2 Variational Inequalities with EMP: A Simple Example

Consider the following simple three dimensional linear example (adapted from Yashtini & Malek (2007) [\[261\]](#)). Let

$$F(x) = \begin{bmatrix} 22x_1 - 2x_2 + 6x_3 - 4 \\ 2x_1 + 2x_2 \\ 6x_1 + 2x_3 \end{bmatrix}, \quad K = \{x \in \mathbb{R}^3 \mid x_1 - x_2 \geq 1, -3x_1 - x_3 \geq -4, 2x_1 + 2x_2 + x_3 = 0, l \leq x \leq u\}, \quad (9)$$

where $l = (-6, -6, -6)^T$, $u = (6, 6, 6)^T$. N.B.: F is not the gradient of any function $\mathbb{R}^3 \rightarrow \mathbb{R}$. This $VI(F, K)$ has a unique solution: $x = (2/3, -1/3, -2/3)$. The problem can be implemented in GAMS with EMP as follows:

```

Set      i /1*3/;
Variable x(i);

x.lo(i) = -6;
x.up(i) = 6;

Equations F(i), h1, h2, h3;

F(i)..   (22*x('1') - 2*x('2') + 6*x('3') - 4)$sameas(i,'1')
         + (2*x('1') + 2*x('2'))$sameas(i,'2')
         + (6*x('1') + 3*x('3'))$sameas(i,'3')
         =n= 0;

h1..     x('1') -x('2') =g= 1;

h2..     -3*x('1') - x('3') =g= -4;

h3..     2*x('1') + 2*x('2') + x('3') =e= 0;

Model linVI / F, h1, h2, h3 /;

File annotations /'%emp.info%'/;
put annotations;
putclose 'vi F x h1 h2 h3';

solve linVI using EMP;

```

Observe that the function F and the constraints h are formulated using standard GAMS syntax. F is implemented as an equation of `type =n=`, which does not imply or enforce any relationship between the left-hand side and the right-hand side. Instead, this relationship is implied by the position of the matching variables (given in the EMP info file) relative to their bounds. The `annotations` in the EMP info file define the structure of the VI: what functions are matched to what variables, and what constraints serve to define the set K . The EMP keyword `vi` indicates that the model is a VI, that the VI function F is matched to the variable x , and that the constraints `h1 h2 h3` define the set K .

Alternatively, the EMP annotations could be written as follows:

```
putclose 'vi F x';
```

Here the equations after the equation-variable pair are omitted. This is acceptable, since by default any equations that are part of the model but are not matched with a variable are automatically used to define the set K .

Since VI problems have no objective, the `short form` of the solve statement is used.

The solver JAMS will reformulate the VI as an MCP and pass this on to an MCP subsolver. The EMP [Summary](#) produced by JAMS will contain the following line:

```

--- EMP Summary
...
VI Functions      = 3
...

```

This output reflects the fact that there were three VI functions in the model above, one for each member of the set i .

Note that there are several VI models in the GAMS EMP Library. For example, the models `[SIMPLEVI]` and `[VI_MCP]` demonstrate how some models can be specified using either MCP or VI syntax. A simple nonlinear VI is given in model `[SIMPLEVI2]`. As the transportation model is so well known, model `[TRANSVI]` demonstrates how it can be cast as a VI.

4.47.3.3 EMP Syntax for Variational Inequalities

The general syntax of the [EMP annotations](#) used to specify variational inequalities is as follows:

```
VI [{var|*}] { [-] equ var} [{[-] equ}]
```

The [EMP keyword](#) `VI` indicates that this is a variational inequality specification. The core of the VI specification is the (list of) equation-variable pair(s): the other parts are optional. A pair matches the equation `equ` with the variable `var`. This indicates that `equ` defines part of the VI function F , and that these rows of F are perpendicular to columns taken from `var`. Multiple equation-variable pairs are allowed. The optional variables before the pairs are called *preceding variables*. These are variables that appear (and are often defined by) the constraints of the model, but they are not matched explicitly via the VI function F . Instead, they are automatically matched with the zero function. See model [\[ZEROFUNC\]](#) for an example and a more detailed discussion. The optional equations after the equation-variable pairs are called *trailing equations*. They define the set K and may be omitted from the VI specification. By default, any equations that are included in the model but are not matched with a variable are automatically used to define the set K . Even though both preceding variables and trailing equations may be omitted from the VI specification, we recommend to explicitly list them, since this clarifies intentions and eliminates ambiguity.

The “-” sign in the syntax above is used to flip (i.e. to reorient or negate) the marked equation, e.g. so that `x**1.5 =L= y` becomes `y =G= x**1.5`. Flipped equations in EMP behave in the same way as [flipped equations in MCP](#).

Note

More than one VI specification may appear in a model. Often, it makes no difference whether multiple equ-var pairs are part of the same or separate VI specifications, but this is not the case in general. For an example, see model [\[SIMPLEVI4\]](#).

4.47.4 Quasi-Variational Inequalities (QVI)

Quasi-variational inequalities are a generalization of the [variational inequality](#) model: in a VI, the feasible set is fixed, while the QVI allows the feasible set to vary with or be a function of the variables in the model. To avoid repetition, we assume you are already familiar with the theory and notation for [VI](#) models. In this section, we present a [mathematical formulation](#) of QVI, give an [example](#) of how QVI can be modeled with GAMS EMP, and introduce the [EMP annotations specific to QVI](#).

4.47.4.1 Quasi-Variational Inequalities: Mathematical Formulation

For a given continuous function $F : \mathbb{R}^n \rightarrow \mathbb{R}^n$ and a point-to-set mapping $K(y) : \mathbb{R}^n \rightarrow \mathbb{R}^n$, the quasi-variational inequality problem $QVI(F, K)$ is to find a point $y^* \in K$ such that:

$$\langle F(y^*), (y - y^*) \rangle \geq 0, \quad \forall y \in K(y^*), \quad (4.19)$$

where $\langle \cdot, \cdot \rangle$ denotes the usual inner product.

If the point-to-set mapping $K(y) : \mathbb{R}^n \rightarrow \mathbb{R}^n$ is constant, then the QVI above reduces to a VI. In order to define $K(x)$ as a function of x it is convenient to introduce a shadow copy x of the variable y . It should be understood that we have only one variable that appears in two forms: the variable of interest y and the parameter variable x . Where y appears, we have a variable in the usual sense, and we take derivatives wrt this variable when deriving optimality conditions. Where x appears, we have a constant variable, i.e. we assume it is fixed when deriving optimality conditions. We can now use a function $g(y, x)$ to define $K(\cdot)$ and express QVI as: find a point $y^* \in K$ (with its associated parameter variable x^*) such that:

$$\langle F(y^*), (y - y^*) \rangle \geq 0, \quad \forall y \text{ s.t. } g(y, x) \leq 0. \quad (4.20)$$

4.47.4.2 Quasi-Variational Inequalities with EMP: A Simple Example

Consider the following simple two dimensional linear example. Let y be the variable of interest with its parameter variable x and let

$$F(y) = \begin{bmatrix} 2y_1 + \frac{8}{3}y_2 - \frac{100}{3} \\ 1.25y_1 + 2y_2 - 22.5 \end{bmatrix}, K(x) = \{y \in \mathbb{R}^2 \mid y_1 + x_2 \leq 15, x_1 + y_2 \leq 20, 0 \leq y, x \leq 11\}. \quad (4.21)$$

This $QVI(F, K)$ has a solution $y = (10, 5)$. The problem can be implemented in GAMS with EMP as follows:

```
set i / 1*2 /;
alias(i,j);

table A(i,j)
      1      2
1      2      [8/3]
2  [5/4]      2      ;

parameters
  b(i) / 1 [100/3], 2 22.5 /
  Cy(i,j) / 1.1 1, 2.2 1 /
  Cx(i,j) / 1.2 1, 2.1 1 /
  rhs(i) / 1 15, 2 20 /
;
positive variables
  y(j) 'variable of interest, aka decision variable'
  x(j) 'parameter variable shadowing y'
;
y.up(j) = 11; x.up(j) = 11;
equations
  F(i) 'FOC for agent optimization models'
  g(i) 'define feasible set K(x) for QVI'
;
F(i).. sum{j, A(i,j)*y(j)} - b(i) =N= 0;

g(i).. sum{j, Cy(i,j)*y(j)} + sum{j, Cx(i,j)*x(j)} =L= rhs(i);

model m / F, g /;
file annotations / '%emp.info%' /;
putclose annotations 'qvi F y x g' ;
solve m using emp;
```

Observe that the function F and the constraints g are formulated using standard GAMS syntax. F is implemented as an equation of [type =n=](#), which does not imply or enforce any relationship between the left-hand side and the right-hand side. Instead, this relationship is implied by the position of the matching variables (given in the EMP info file) relative to their bounds. The [annotations](#) in the EMP info file define the structure of the QVI: what functions are matched to what variables, and what constraints serve to define the mapping $K(x)$. The [EMP keyword](#) `qvi` indicates that the model is a QVI, that the QVI function F is matched to the variable-of-interest y with its parameter variable x , and that the constraints g define the mapping $K(x)$.

Since QVI problems have no objective, the [short form](#) of the solve statement is used.

The solver JAMS will reformulate the QVI as an MCP and pass this on to an MCP subsolver. The [EMP Summary](#) produced by JAMS will contain the following lines:

```

--- EMP Summary
...
VI Functions          = 2
QVI Parameters        = 2
...

```

This output reflects the fact that there were two VI functions in the model above, one for each member of the set *i*, and that each of the variables matched to these functions was shadowed by a parameter variable.

Note that there are two QVI models in the GAMS EMP Library, the models `[SIMPLEQVI1]` and `[SIMPLEQVI2]` (an expanded version of the example shown above).

4.47.4.3 EMP Syntax for Quasi-Variational Inequalities

The general syntax of the [EMP annotations](#) used to specify quasi-variational inequalities is as follows:

```
QVI {0 var [ parameterVar] | [-] equ var [ parameterVar] } { [-] equ}
```

The [EMP keyword](#) `QVI` indicates that this is a quasi-variational inequality specification. All variables and equations included in a QVI must be listed explicitly. First we have the VI functions, their matching variables, and (optionally) the parameter variables shadowing these variables. Note that in a QVI there are no *preceding variables* as we have in a [VI spec](#):: instead, the implied match to the zero function is indicated by the digit 0 appearing where an equation symbol would otherwise appear. After the function/variable pairs have been listed, the *trailing equations* (i.e. the equations/constraints defining the mapping $K(\cdot)$) appear.

4.47.5 Equilibrium Problems

While optimization problems have *one* decision maker that controls all decision variables, equilibrium problems are a collection of optimization problems and variational inequalities, each controlled by a *different agent*. We typically assume that each variable and each equation is controlled by or belongs to exactly one agent. Variables that are controlled by one agent but appear in the equations of a second agent are regarded as fixed or exogenous variables by that second agent: when taking first-order conditions, the second agent won't take derivatives wrt these exogenous variables. Later we will relax this assumption and introduce equilibrium problems with [shared constraints](#) and [shared variables](#). Note that in this section we will discuss equilibrium problems of the Nash type, i.e. where all agents are on the same level, each assuming the decisions or strategies of the other agents are known and fixed. Equilibrium problems of the Stackelberg type, where there are leaders and followers, are covered in section [Bilevel Programs](#).

We start with the [mathematical formulation](#) of an equilibrium problem, next present two examples, and conclude with a description of the [EMP annotations for equilibrium problems](#).

4.47.5.1 Equilibrium Problems: Mathematical Formulation

Consider the following equilibrium problem with N agents solving minimization problems and one agent solving a [variational inequality](#):

$$\begin{aligned} &\text{Find } (x_1^*, \dots, x_N^*, p^*) \text{ satisfying} \\ &x_i^* \in \arg \min_{x_i} f_i(x_i, x_{-i}^*) \\ &\quad \text{s.t. } g_i(x_i, x_{-i}^*) \leq 0, \text{ for } i = 1, \dots, N, \\ &p^* \in \text{SOL}(H(p, x^*), K(x^*)), \\ &\quad \text{where } K(x^*) = \{p \mid w(p, x^*) \leq 0\}. \end{aligned} \tag{10}$$

Note that $f_i(x_i, x_{-i})$ denotes the objective function of the problem of agent i , $g_i(x_i, x_{-i})$ are the constraints relating to this optimization problem and $x_{-i} = (x_1, \dots, x_{i-1}, x_{i+1}, \dots, x_N)$ denotes the decisions of the other agents. Further, $\text{SOL}(H, K)$ represents the solution set of the variational inequality $VI(H, K)$.

This problem can be implemented with EMP as follows:

```
Set i ;
Variables obj(i), x(i), p;
Equations deff(i), defg(i), defH, defw;

*Definitions of equations are omitted

Model equil / deff, defg, defH, defw /;

File myinfo /'%emp.info%'/;
put myinfo 'equilibrium';
loop(i,
    put / 'min', obj(i), x(i), deff(i), defg(i);
);
put 'vi defH p defw' /;
putclose myinfo;

solve equil using EMP;
```

Note that the GAMS variable `obj(i)` holds the value of $f_i(x)$, `x(i)` represents the variable x_i and `p` denotes the variable p , of course. The equations `deff(i)` and `defg(i)` are closed-form definitions of the objective function $f_i(x)$ and the constraint $g_i(x)$ respectively. The equation `defH` defines the variational inequality function H and the equation `defw` defines the set K . The [EMP annotations](#) found in the file `emp.info` specify the equilibrium structure of the model:

```
equilibrium
min obj('1') x('1') deff('1') defg('1')
...
min obj('N') x('N') deff('N') defg('N')
vi defH p defw
```

The [EMP keyword](#) `equilibrium` indicates that the annotations are for an equilibrium problem. Each of the EMP keywords `min` begins a new optimization problem (owned by a new agent), where each problem has its own objective variable, decision variables, and equations / constraints. For example, the first agent minimizes `obj('1')`, controls or owns `x('1')`, and is subject to the constraints `deff('1')` and `defg('1')`. If other variables like `x('2')` and `x('3')` appear in `deff('1')` and `defg('1')`, they will be treated as exogenous by the first agent. This specification is consistent with the formulation above in (9). Each agent's optimization problem can be easily (re)constructed given the EMP annotations. Following the optimization problems of the N agents we have the [VI specification](#) for agent p . The [EMP keyword](#) `vi` is followed by the equation-variable pair `defH p` defining the VI function H and the equation `defw` that defines the feasible set K .

Note that the [short form](#) of the [solve statement](#) is used for equilibrium problems. Objective variables (if and when they exist) belong to individual agents, not to the model as a whole.

4.47.5.2 Equilibrium Problems with EMP: A Simple Example

Consider the following example from Kim & Ferris (2017) [143]. In this economic equilibrium problem there are three agents: one profit-maximizing producer, one utility-maximizing consumer and a market that determines the price of three commodities based on production and demand. The problem data include a technology matrix A , where the entry $a_{ij} > 0$ denotes the output of the commodity i for each unit of activity of producer j and $a_{ij} < 0$ denotes the respective input. Further, an initial endowment b and the demand function $d(p)$ is given, where p is the price. The consumer maximizes her utility within her budget, which depends on the price p and the initial endowment b . Let y represent the activity of the producer, x represent the demand of the consumer and p represent the prices of commodities. Then (y^*, x^*, p^*) is a general equilibrium if it satisfies the following:

$$\begin{array}{ll}
 -A^T p^* \geq 0 & \text{No positive profit for each activity} \\
 b + Ay^* - d(p^*) \geq 0 & \text{No excess demand} \\
 p^* \geq 0, y^* \geq 0 & \text{Nonnegativity} \\
 -A^T p^* \perp y^* & \text{No activity for earning negative profit and positive activity implies balanced profit} \\
 b + Ay^* - d(p^*) \perp p^* & \text{Zero price for excess supply and market clearance for positive price}
 \end{array} \tag{4.22}$$

The code for the respective model is given below. Note that instead of using the consumer demand function $d(p)$ in its explicit form, we introduce a utility-maximizing consumer with demand x .

```

set i 'commodities' / 1*3 /;

variable u 'consumer utility';
positive variables
    y      'activity of the producer'
    x(i)   'Marshallian demand of the consumer'
    p(i)   'prices'
;
parameters
    A(i) 'technology matrix' / 1 1, 2 -1, 3 -1 /
    s(i) 'budget share'      / 1 0.9, 2 0.1, 3 0 /
    b(i) 'endowment'        / 1 0, 2 5, 3 3 /
;
equations
    profit      'profit of activity'
    mkt(i)      'constraint on excess demand'
    udef        'Cobb-Douglas utility function'
    budget      'budget constraint'
;
profit.. -sum(i, A(i)*p(i)) =g= 0;

mkt(i).. b(i) + A(i)*y - x(i) =g= 0;

udef.. u =e= sum(i, s(i)*log(x(i)));

budget.. sum(i, p(i)*x(i)) =l= sum(i, p(i)*b(i));

model m / mkt, profit, udef, budget /;

file empinfo /'%emp.info%'/; putclose empinfo
'equilibrium' /
' max', u, 'x', udef, budget /
' vi profit y' /
' vi mkt p' /

```

```

;
* the second commodity is used as a numeraire
p.fx('2') = 1;
x.l(i) = 1;

solve m using EMP;

```

Observe that in the [EMP annotations](#) the problems of the three agents are specified after the [EMP keyword](#) `equilibrium`: the consumer solves a maximization problem (where the utility `u` is maximized) and the activities of the producer and the price-setting market are expressed as VI. As there are three commodities, the first VI actually generates three VI functions, one for each commodity. Thus there are three agents and four VI functions in the equilibrium problem. This is reflected in the [EMP Summary](#) in the listing file:

```

--- EMP Summary
...
VI Functions           = 4
Equilibrium Agent     = 3
...

```

In the GAMS EMP Library there are several models that have a similar form, e.g. Scarf's activity analysis model [[SCARFEMP-DEM](#)] and the simple equilibrium problem [[SIMPEQUIL](#)]. The latter demonstrates that there are equilibrium problems where the optimization problems of the individual agents are solvable, but the overall equilibrium problem does not have a solution.

4.47.5.3 Equilibrium Problems with EMP: Example with Dual Variables

In many applications equilibrium problems come with a twist: the dual variable associated with a constraint in the problem of one agent appears *exogenously* in the problem of another agent. The following simple example with two agents is from model [[DUALVAR](#)] in the GAMS EMP Library.

$$\begin{aligned}
 &\text{Problem of the first agent: } \text{Min}_{(v,w)} \quad z = v + w \\
 &\text{s.t.} \quad \sqrt{v+1} + 2w \geq 2 \quad (\perp \quad u \geq 0) \\
 &\quad \quad v, w \geq 0
 \end{aligned} \tag{11}$$

$$\text{Problem of the second agent: } VI : \quad F(y) := y - 4u + 1 \quad (\perp \quad y \text{ free})$$

N.B.: the variable u that appears in the problem of the second agent is the dual multiplier (aka shadow price) of the first agent's constraint. This equilibrium problem can be modeled in GAMS with EMP as follows:

```

positive variables
v      'belongs to min agent'
w      'belongs to min agent'
u      'dual of min constraint'
;
free variables
y      'belongs to VI agent'
z      'objective var'
;
equations
defz   'objective def'
g      'constraint for min agent'

```

```

    Fy    'VI function'
    ;
defz..   v + w =e= z;

g..      sqrt(v+1) + 2*w =g= 2;

Fy..     y - 4*u + 1 =n= 0;

Model opt 'min agent and VI agent' / defz, g, Fy /;

File empinfo / '%emp.info%' /;  putclose empinfo
'equilibrium' /
' min z v w defz g' /
' vi Fy y' /
' dualvar u g' /
;
defz.m = -1;
g.m = 0.5;    Fy.m = 1;
v.l = 0;      w.l = 0.5;
y.l = 1;      u.l = 0.5;

solve opt using emp;

```

The [EMP info file](#) contains the [EMP keyword](#) `equilibrium` followed by the specifications for the two agents: a minimization problem for the first agent and a VI for the second agent. The special relationship between the variable `u` and the equation `g` is declared via the EMP keyword `dualvar` followed by the respective variable-equation pair. Recall our usual assumption that each variable and each equation is owned or controlled by exactly one agent. Since variable `u` is tied to equation `g` and `g` is owned by the first agent, variable `u` is owned by the first agent also.

Besides the number of equilibrium agents and the number of VI functions, the [EMP Summary](#) lists the number of dual variable maps:

```

--- EMP Summary
...
Dual Variable Maps   = 1
...
VI Functions         = 1
Equilibrium Agent    = 2
...

```

Note

Although the example above contained an optimizing agent and a VI agent, dual variables most often occur in equilibrium problems with several optimizing agents.

Other examples with dual variables in the GAMS EMP Library include a formulation of the well-known transportation model as an equilibrium problem [[TRANSEQL](#)], Scarf's activity analysis model [[SCARFEMP-PRIMAL](#)] and the general equilibrium model [[TWO3EMP](#)].

4.47.5.4 EMP Syntax for Equilibrium Problems

The EMP framework provides the following general syntax to specify equilibrium problems:

```
Equilibrium
{VIsol {equ}}
{Implicit {var equ}}
{MAX|MIN obj {var|*} {[-] equ}}
{VI {var|*} {[-] equ var} {[-] equ}}
{DualVar {var [-] equ}}
```

The [EMP keyword](#) `Equilibrium` indicates that the specifications that follow define the structure of an equilibrium problem. The `MAX`, `MIN`, and `VI` keywords specify agents in the problem, while the rest of the keywords are optional modifiers used to adjust the structure of the agent models or the meaning of the equations they contain.

Note

An equilibrium problem must contain at least one agent, i.e. must contain one of the keywords `MAX`, `MIN`, or `VI`.

The EMP keyword `VIsol` identifies a shared constraint(s) and specifies the MCP reformulation to use for it: see section [Equilibrium Problems with Shared Constraints](#) below for details. The keyword `Implicit` identifies a shared variable and its defining constraint: see section [Equilibrium Problems with Shared Variables](#) below for details. The keywords `MAX` and `MIN` each begin the specification of an optimization agent and are followed by the objective variable `obj` and the other variables and equations owned by the agent, as described in the [formulation](#) and [example](#) above. The keyword `VI` begins the specification of a VI agent: see the section on [VI](#) above for details. Finally, the EMP keyword `DualVar` specifies that the variable `var` is the Lagrange multiplier for the equation `equ`. For examples, see sections [Equilibrium Problems with EMP: Example with Dual Variables](#) and [Embedded Complementarity Systems](#).

The symbol `'*` specifies that the default or automatic assignment of variables to this agent be used, i.e. the set of variables used in the equations owned by this agent but not explicitly or otherwise assigned to another agent. Note that if a variable occurs in equations owned by multiple agents and is not explicitly assigned to any agent, the default assignment is not well defined and using it will be flagged as an error. To avoid confusion and promote clarity, we recommend that modelers use explicit variable lists and avoid the `'*` symbol.

The `"-"` sign in the syntax above is used to flip (i.e. to reorient or negate) the marked equation, e.g. so that `x**1.5 =L= y` becomes `y =G= x**1.5`. Flipped equations in EMP behave in the same way as [flipped equations in MCP](#).

Note

When the EMP keyword `equilibrium` appears in the EMP annotations, the [solve statement](#) takes the [short form](#) also used for complementarity problems in GAMS.

4.47.6 Embedded Complementarity Systems

Embedded complementarity systems of the following form arise frequently in applications:

$$\begin{array}{ll} \text{Min}_x & f(x, y) \\ \text{s.t.} & g(x, y) \leq 0 \quad (\perp \lambda \geq 0) \end{array} \quad (12)$$

$$H(x, y, \lambda) = 0 \quad (\perp y \text{ free}) \quad (4.23)$$

Note that the optimization problem is over the variable x and it is parametrized by the variable y . The choice of y is determined by the complementarity relationships represented here by H .

From an EMP perspective, there are two ways to [annotate](#) a GAMS model to specify the model above: we will describe both below. These approaches provide equivalent additional information that prompts the EMP tool to automatically create the following MCP:

$$\begin{array}{ll} 0 = \nabla_x L(x, y, \lambda) & \perp x \text{ free} \\ 0 \leq -\nabla_\lambda L(x, y, \lambda) & \perp \lambda \geq 0 \\ 0 = H(x, y, \lambda) & \perp y \text{ free,} \end{array} \quad (13)$$

where the Lagrangian is defined as

$$L(x, y, \lambda) = f(x, y) + \lambda^T g(x, y). \quad (4.24)$$

The first approach uses the [EMP keywords](#) `dualequ` and `dualvar`, as contained in the model [\[FERRIS43\]](#).

```
variables          obj, x, y;
positive variable lambda;

equations defobj, g, H;

* We omit the equation definitions here.

model ecs /defobj, g, H/;

file empinfo / '%emp.info%' /; putclose empinfo
'dualequ H y' /
'dualvar lambda g' / ;

solve ecs using EMP minimizing obj;
```

The external constraint H is expressed as a standard GAMS equation. The [long form](#) of the solve statement is used here, which implies the existence of a single optimizing agent that by default owns all equations and variables. The first EMP keyword `dualequ` indicates that the equation `H` and the variable `y` do not belong to the optimizing agent: instead, `y` is treated as an exogenous variable by this agent, and this agent is assumed to know nothing about the functional form of `H`, so that `H` will not appear in any first-order conditions. Instead, a complementarity relationship between the function defined by `H` and the variable `y` is required to exist at optimality. The EMP keyword `dualvar` indicates that the variable `lambda` is the dual of the equation `g`. As a result `lambda` will be treated exogenously wherever it appears. Given the [EMP annotations](#) for this model, JAMS will automatically reformulate the problem as the MCP in (12) and pass this model to an MCP subsolver.

The [EMP Summary](#) produced by JAMS contains the following lines:

```

--- EMP Summary
    Dual Variable Maps  = 1
    Dual Equation Maps  = 1

```

The second modeling approach recasts the problem above as an [equilibrium problem](#) with two agents: the first agent solves a minimization problem and the second agent solves a VI. The algebra in the model remains the same: only the EMP annotations and the solve statement change.

```

putclose empinfo
'equilibrium' /
' min obj x g defobj' /
' vi H y' /
' dualvar lambda g' /

solve ecs using EMP;

```

The [EMP keyword](#) `equilibrium` indicates we have an equilibrium problem. The EMP keyword `min` indicates that the first agent solves a minimization problem with the objective variable `obj`, the decision variable `x` and the equations `g` and `defobj`. In contrast to the first approach, where the default (because of the long-form solve statement) is one optimizing agent owning all equations, here we specify the first agent's minimization model explicitly and from the ground up. As a result it doesn't contain the equation `H` and we do not use the `dualqu` keyword to take `H` out. Instead, the EMP keyword `vi` specifies that the second agent solves a VI defined by `H` matched with the variable `y`. The `dualvar` keyword functions here as it did in the previous example.

The [EMP Summary](#) produced by JAMS contains the following lines:

```

--- EMP Summary
...
Dual Variable Maps  = 1
Dual Equation Maps  = 0
VI Functions        = 1
Equilibrium Agent    = 2
...

```

Other examples of embedded complementarity systems in the GAMS EMP Library include the simple equilibrium problem [[SIMPEQUIL2](#)], the equilibrium problem formulation of the well-known transportation model [[TRANSECS](#)], the PIES energy equilibrium problem [[PIES](#)], the pure exchange model [[NEGISHI](#)] and the spatial price equilibrium model [[HARK-MONOP](#)].

It's worthwhile highlighting the differences between the `dualvar` and `dualqu` keywords, as the two are easily and frequently confused. The `dualvar` keyword makes reference to a constraint owned by an optimizing agent. Derivatives of this constraint, multiplied by the variable referenced, appear in the first-order optimality conditions for this agent. The `dualvar` keyword allows us to use this variable or multiplier explicitly (and in a sense exogenously) in the model algebra. In contrast, the `dualqu` keyword indicates that, contrary to what the default is, an equation is not owned by any optimizing agent, so no derivatives of this equation will appear in any FOC or in the reformulated model. The two are similar in that if a variable `x` appears with either `dualvar` or `dualqu`, no derivatives w.r.t. `x` will appear in the model reformulation.

<code>dualvar x F</code>	<code>dualqu F x</code>
Variable symbol appears first	Equation symbol appears first
F is owned by an optimizing agent	F is a system constraint
Derivatives of F appear in FOC	No derivatives of F appear in derived model
Does not change ownership of F	F is taken away from an optimizing agent

Table 1: Differences between dualvar and dualequ

4.47.7 Equilibrium Problems with Shared Constraints

In the [equilibrium problems](#) we have discussed so far, each variable and each constraint was owned by a single agent. In this section we relax the assumption that each constraint has to be controlled by a single agent and introduce *shared constraints*. Shared constraints are constraints that appear in the problems of several agents. They are mainly used to model resources shared among agents. Note that the examples in this section are from Kim & Ferris (2017) [\[143\]](#).

Consider the following example:

$$\begin{aligned}
 &\text{Find } (x_1^*, \dots, x_N^*) \text{ satisfying} \\
 &x_i^* \in \arg \min_{x_i} \quad f_i(x_i, x_{-i}^*) \\
 &\text{s.t.} \quad \quad \quad g_i(x_i, x_{-i}^*) \leq 0 \\
 &\quad \quad \quad h(x_i, x_{-i}^*) \leq 0, \quad \text{for } i = 1, \dots, N.
 \end{aligned} \tag{14}$$

The constraints g_i are owned by agent i , while the constraint h is shared by all agents. This example can be reformulated in two different ways, each with its own [EMP annotations](#) and resulting MCP. However, both share the model formulation below:

```

variables obj(i), x(i);
equations deff(i), defg(i), defh;

model sharedc / deff, defg, defh /;

```

Observe that the equation `defh` implementing the shared constraint $h(x) \leq 0$ is not indexed: it exists once, not once per agent. The first way to write the EMP annotations is as follows:

```

file empinfo / '%emp.info%' /;
put empinfo 'equilibrium' /;
loop(i,
    put 'min', obj(i), x(i), deff(i), defg(i), defh; /;
);
putclose empinfo;

```

Here the equation `defh` appears in the minimization problem of each agent. As the equation `defh` is not indexed by agent and appears in the problem of each agent, it is easy to see that it is a shared constraint. Given these annotations, the EMP framework aggregates the FOC for each agent to create the following MCP:

$$\begin{aligned}
 F(z) &= ((F_i(z)^T)_{i=1}^N)^T, & z &= ((z_i^T)_{i=1}^N)^T, \\
 F_i(z) &= \begin{bmatrix} \nabla_{x_i} f_i(x) - \nabla_{x_i} g_i(x) \lambda_i - \nabla_{x_i} h(x) \mu_i \\ g_i(x) \\ h(x) \end{bmatrix}, & z_i &= \begin{bmatrix} x_i \\ \lambda_i \leq 0 \\ \mu_i \leq 0 \end{bmatrix}, \quad \text{for } i = 1, \dots, N.
 \end{aligned} \tag{15}$$

Note that the equation $h(\cdot)$ is replicated for each agent and each agent is assigned a separate multiplier μ_i .

Attention

By default, the solver JAMS does not allow shared constraints. The option `SharedEqu` needs to be specified in the option file `jams.opt` if shared constraints are intended, otherwise an error is reported when they are detected. This cautious default helps minimize the number of surprising results.

A full model including the JAMS option file is given [below](#).

The second way to write the EMP annotations uses the EMP keyword `VIso1` to specify that a *variational equilibrium* be computed, i.e. a solution where the multipliers μ_i are all equal. The `VIso1` keyword should appear *after* the EMP keyword `equilibrium` and *before* the descriptions of agent models.

```
put / 'VIso1 defh';
```

The multipliers to make equal (or, equivalently, the constraints not to replicate) are indicated by the equation name(s) following the keyword `VIso1`. These constraints appear once in the resulting MCP, not once per agent. The EMP tool creates the following MCP:

$$\begin{aligned} F(z) &= ((F_i(z)^T)_{i=1}^N, F_h(z)^T)^T, & z &= ((z_i^T)_{i=1}^N, z_h^T)^T, \\ F_i(z) &= \begin{bmatrix} \nabla_{x_i} f_i(x) - \nabla_{x_i} g_i(x) \lambda_i - \nabla_{x_i} h(x) \mu \\ g_i(x) \end{bmatrix}, & z_i &= \begin{bmatrix} x_i \\ \lambda_i \leq 0 \end{bmatrix}, \quad \text{for } i = 1, \dots, N, \\ F_h(z) &= [h(x)], & z_h &= [\mu \leq 0]. \end{aligned} \quad (16)$$

If there are no constraints $g_i(x)$, then - assuming a constraint qualification - the equilibrium problem with the shared constraint corresponds exactly to the variational inequality $VI(F, X)$, where the set $X = \{x \mid h(x) \leq 0\}$ and $F(x) = ((\nabla_{x_i} f_i(x)^T)_{i=1}^N)^T$. This corresponds in turn to the solution of the first MCP (with the replicated shared constraints) in case that solution has the property that the multipliers μ_i are all equal. This is what gives the latter solution its name *variational equilibrium*. If the equilibrium problem with the shared constraint has a unique solution, both MCP reformulations will have the same solution. Otherwise, the two MCPs that correspond to the two different EMP annotations may have different solutions.

An example for shared constraints is the pollution of a river basin in Haurie & Krawczyk (1997) [127] and Krawczyk & Uryasev (2000) [147], where the total amount of pollutants that may be dumped in a river is restricted. This implies that the environmental constraints of some pollutant-producing agents are shared. This example can be formulated as follows, where i is the agent index and m denotes the number of shared constraints.

$$\begin{aligned} \text{Find } & (x_1^*, x_2^*, x_3^*) \text{ satisfying} \\ x_i^* \in & \arg \min_{x_i} (c_{1i} + c_{2i}x_i)x_i - \left(d_1 - d_2 \left(\sum_{j=1, j \neq i}^3 x_j^* + x_i\right)\right)x_i \\ \text{s.t. } & \sum_{j=1, j \neq i}^3 x_j^*(u_{jm}e_jx_j^*) + u_{im}e_ix_i \leq K_m, \\ & \text{for } i = 1, 2, 3, m = 1, 2, \\ \text{where } & (c, d, e, u, K) \text{ is the problem data.} \end{aligned} \quad (17)$$

Here three agents produce some commodities and aim to maximize their profit. The term $(c_{1i} + c_{2i}x_i)x_i$ denotes the total cost for each agent i and the term $(d_1 - d_2(\sum_{j=1, j \neq i}^3 x_j^* + x_i))x_i$ represents the revenue for each agent. The amount of pollutants each agent dumps in the river is limited by the two shared constraints. This problem can be implemented in GAMS with EMP as follows:

```

Sets i / 1*3 /
      m / 1*2 / ;
alias(i,j) ;

Variable      obj(i) ;
Positive Variable x(i) ;

Parameters K(m) / 1 100, 2 100 /
            d1 / 3 /
            d2 / 0.01 /
            e(i) / 1 0.5, 2 0.25, 3 0.75 / ;

Table c(m,i)
      1      2      3
1  0.1  0.12  0.15
2  0.01 0.05  0.01 ;

Table u(i,m)
      1      2
1  6.5  4.583
2  5.0  6.250
3  5.5  3.750 ;

Equations objdef(i)
          cons(m) ;

objdef(i).. obj(i) =e= (c('1',i) + c('2',i)*x(i))*x(i) - (d1 - d2*sum(j, x(j)))*x(i);

cons(m).. sum(i, u(i,m)*e(i)*x(i)) =l= K(m);

Model m_shared / objdef, cons /;

File empinfo / '%emp.info%' /;
put empinfo 'equilibrium' /;
put 'VIsol cons' /;
loop(i,
  put 'min', obj(i), x(i), objdef(i), 'cons' /;
);
putclose empinfo;

$echo SharedEqu > jams.opt
m_shared.optfile = 1;

solve m_shared using emp;
display x.l, cons.m;

```

Note that the shared environmental constraints are expressed with the equation `cons`. In the EMP annotations, we have chosen the formulation with the EMP keyword `VIsol`. It leads to the solution $x^* = (21.145, 16.028, 2.726)$. Alternatively, we could delete the line with the EMP keyword `VIsol` and thus prompt the framework to compute the MCP in (15), resulting in the solution $x^* = (0, 6.473, 22.281)$.

4.47.8 Equilibrium Problems with Shared Variables

In the [last section](#), we relaxed the restriction that each constraint has to be controlled by a single agent and introduced *shared constraints*. In this section, we go a step further and allow *shared variables*. Note that the content of this section is adapted from Kim & Ferris (2017) [143].

First, we introduce the notion of *implicit variables*. In mathematical terms, a variable y is called an implicit variable if for each value of x there is at most one value of y satisfying $(y, x) \in X$. For such implicit variables there exists one and only one function $g(\cdot)$ such that $(g(x), x) \in X$, where g is defined over the set $\{x \mid \exists y \text{ such that } (y, x) \in X\}$. The set X is called the *defining constraint* of the variable y : the value of y is implicitly defined by the value of x via the defining constraint. In the current implementation, the defining constraint may only be represented as a system of equations and implicit variables must be free variables in GAMS.

Shared variables in equilibrium problems are implicit variables that have the same defining constraint for all agents that share the variable. Hence, the defining constraint becomes a shared constraint. Consider the following equilibrium problem with the shared decision variable y and its defining constraint $X = \{(y, x) \mid H(y, x) = 0\}$:

$$\begin{array}{ll} \text{Find} & (y^*, x_1^*, \dots, x_N^*) \text{ satisfying} \\ (y^*, x_i^*) \in & \arg \min_{y, x_i} f_i(y, x_i, x_{-i}^*) \\ & \text{s.t.} \quad H(y, x_i, x_{-i}^*) = 0, \quad \text{for } i = 1, \dots, N, \\ & \text{where} \quad H : \mathbb{R}^{m+n} \rightarrow \mathbb{R}^m, y \in \mathbb{R}^m \end{array} \quad (18)$$

Note that there are N agents, m is the dimension of the variable y and $n = \sum_i n_i$, where n_i is the dimension of x_i . Assuming we have 4 agents, this example can be implemented in GAMS EMP as follows:

```
Set          i / 1*4/;
Variables obj(i), x(i), y;

Equations deff(i), defH;

Model        sharedv / deff, defH /;

File empinfo / '%emp.info%' /;
put empinfo 'equilibrium' /;
put 'implicit y defH' /;
loop (i,
    put 'min', obj(i), x(i), y, deff(i) /;
);
putclose empinfo;

solve sharedv using EMP;
```

In the [EMP annotations](#), the [EMP keyword](#) `implicit` is used to declare the implicit variable `y` and its defining constraint `defH`. Note that the keyword `implicit` must be followed by variable-constraint pairs. If multiple pairs are specified with a single keyword `implicit`, they will be augmented to form a single vector of implicit variables and its defining constraint.

Note

Implicit variables are declared *before* the agent problems are defined.

Observe that the shared variable `y` appears in the problem specification for each agent. However, the defining equation `defH` does not appear in each problem specification, since it is assumed to be part of the implicit variable.

4.47.8.1 Reformulation Strategies for Equilibrium Problems with Shared Variables

Like other equilibrium problems, equilibrium problems with shared variables are reformulated as MCPs by the EMP tool. Users can choose between three different reformulation strategies if shared decision variables are involved. In the first strategy, the shared variables are *replicated* for each agent and the respective KKT conditions are computed, resulting in the following MCP:

$$\begin{aligned} F(z) &= [(F_i(z)^T)_{i=1}^N]^T, & z &= [(z_i^T)_{i=1}^N]^T \\ F_i(z) &= \begin{bmatrix} \nabla_{x_i} f_i(x, y) - (\nabla_{x_i} H(y, x))\mu_i \\ \nabla_{y_i} f_i(x, y) - (\nabla_{y_i} H(y, x))\mu_i \\ H(y_i, x) \end{bmatrix}, & z_i &= \begin{bmatrix} x_i \\ y_i \\ \mu_i \end{bmatrix}. \end{aligned} \quad (19)$$

Note that in this MCP the constraint H and the variable y are replicated N times. The size of the MCP is $(n + 2mN)$. This reformulation is obtained by specifying the option `ImplVarModel=replication` in the JAMS options file.

The second reformulation strategy involves *switching* each shared variable with the multiplier associated with its defining equation. This technique can be applied if all of the following three conditions are met:

1. The defining constraint is given as an equation.
2. The dimension of the range of the defining constraint equals the dimension of the shared variable.
3. The shared variable is a free (unbounded) variable.

The switching strategy uses the fact that in an MCP, the matching between free variables and equations is somewhat arbitrary: it can be re-assigned without changing the solution. Applying this technique, we obtain the following MCP:

$$\begin{aligned} F(z) &= [(F_i(z)^T)_{i=1}^N, F_h(z)^T]^T, & z &= [(z_i^T)_{i=1}^N, z_h^T]^T \\ F_i(z) &= \begin{bmatrix} \nabla_{x_i} f_i(x, y) - (\nabla_{x_i} H(y, x))\mu_i \\ \nabla_{y_i} f_i(x, y) - (\nabla_{y_i} H(y, x))\mu_i \\ H(y, x) \end{bmatrix}, & z_i &= \begin{bmatrix} x_i \\ \mu_i \end{bmatrix} \\ F_h(z) &= [H(y, x)], & z_h &= [y]. \end{aligned} \quad (20)$$

Observe that in this MCP, the defining constraint H and the shared variable y appear only once. Thus the size of the problem is reduced to $(n + mN + m)$. The EMP framework will use this reformulation if the option `ImplVarModel=switching` is specified in the JAMS option file. This is currently the default strategy used.

The third strategy is selected by specifying option `ImplVarModel=substitution` in the JAMS option file. It uses the implicit function theorem to *substitute* the multipliers μ_i by new variables Λ_i , where $\Lambda_i = \nabla_{x_i} H(\nabla_y H)^{-1}$. This technique may be applied when the [three conditions](#) of the switching strategy are satisfied, and in addition, the implicit function theorem holds for the defining constraints. The basic idea is to regard the shared variable y as a function of other non-shared variables and apply the derivative. At each solution to the problem (y^*, x^*) , there exists a locally defined implicit function $h_{x^*}(x)$ such that $y^* = h_{x^*}(x^*)$ and $H(h_{x^*}(x), x) = 0$ for each x in some neighborhood of x^* . It can be shown that given the implications of the implicit function theorem and the new variables Λ_i , the equilibrium problem can be reformulated as the MCP that follows. However, we omit a step-by-step mathematical derivation here, it is given in Kim & Ferris (2017) [143].

$$\begin{aligned} F(z) &= [(F_i(z)^T)_{i=1}^N, F_h(z)^T]^T, & z &= [(z_i^T)_{i=1}^N, z_h^T]^T \\ F_i(z) &= \begin{bmatrix} \nabla_{x_i} f_i(x, y) - (\nabla_{y_i} f_i(x, y))\Lambda_i \\ \nabla_y H(y, x)\Lambda_i - (\nabla_{x_i} H(y, x)) \end{bmatrix}, & z_i &= \begin{bmatrix} x_i \\ \Lambda_i \end{bmatrix} \\ F_h(z) &= [H(y, x)], & z_h &= [y]. \end{aligned} \quad (21)$$

The size of this MCP is $(n + mn + m)$. It can be significantly reduced if the shared variable is *explicitly* defined, for example, $H(y, x) = y - h(x)$. In this case, $(\nabla_y H)^{-1}$ is the identity matrix, therefore it is not necessary to introduce the variables Λ_i and the MCP takes the following form:

$$\begin{aligned} F(z) &= [(F_i(z)^T)_{i=1}^N, F_h(z)^T]^T, & z &= [(z_i^T)_{i=1}^N, z_h^T]^T \\ F_i(z) &= [\nabla_{x_i} f_i(x, y) - \nabla_{x_i} H(y, x) \nabla_y f_i(x, y)], & z_i &= [x_i] \\ F_h(z) &= [H(y, x)], & z_h &= [y]. \end{aligned} \quad (22)$$

The size of this MCP is $(n + m)$, which is a huge decrease compared to the other formulations. Note that the EMP framework detects automatically if the shared variable is explicitly defined and exploits this fact. In the following table an overview of the size of the MCP for the different reformulation techniques is given.

Strategy	Size of the MCP
Replication	$(n + 2mN)$
Switching	$(n + mN + m)$
Substitution (implicit)	$(n + mn + m)$
Substitution (explicit)	$(n + m)$

Table 2: Size of the Reformulated MCP For Different Reformulation Techniques

4.47.8.2 Equilibrium Problems with Shared Variables: A Simple Example

The following simple example computes a saddle point of the Lagrangian associated with a minimization over x subject to a single equality constraint with dual multiplier y . The GAMS EMP implementation is from Youngdae Kim. The primal (minimizing) and dual (maximizing) agents share the variable L containing the value of the Lagrangian, as well as its defining equation **defL**:

```
set i / 1*2 /;
variables
  L      'Lagrangian function: f(x) - y * h(x)'
  x(i)  'primal variables'
  y      'dual variable'
;
equation defL;
defL..
  L =e= sum{i, sqr(x(i)-1)} - y*(sum{i, x(i)} - 4);

model m / defL /;
file empinfo / '%emp.info%' /; putclose empinfo
  'equilibrium' /
  'implicit L defL' /
  ' min L x' /
  ' max L y' /
;

solve m using emp;
```

Note that the variable L is not indexed and it appears in the optimization problem of each agent. It is declared to be an implicit variable (using the keyword **implicit**) in the first line following the **equilibrium** keyword. Its defining constraint **defL** is listed only once, in this same line: it does not appear in the problem specification of each agent. By modeling the Lagrangian as a shared variable, its defining equation does not have to be replicated for each agent.

For other, more complex examples, both with shared decision variables and with a shared objective variable, see Kim & Ferris 2017 [143].

4.47.9 Bilevel Programs

Bilevel programs are mathematical programs with optimization problems in their constraints. The main problem is called the *upper-level* problem or the *leader* and the nested problem is called the *lower-level* problem or the *follower*. A simple example is the bilevel programming problem that optimizes an upper-level objective over constraints that include a lower-level optimization problem. A famous example from economics is the Stackelberg game, where there is one leader and many followers. Bilevel programming is used in many areas, for example the design of optimal tax instruments: the tax instrument is modeled in the upper level and the clearing market is modeled in the lower level.

In this section we first present a [mathematical formulation](#) of a bilevel program with one follower and introduce the respective EMP annotations. Then we present three examples: a [simple first example](#), an [example with a variational inequality](#) as the lower-level problem and an [example with multiple followers](#) that form a Nash equilibrium. We conclude the section with a short discussion of the general [EMP syntax for bilevel programs](#).

4.47.9.1 Bilevel Programs: Mathematical Formulation

A bilevel program with one leader and one follower can be expressed as follows:

$$\begin{array}{ll} \text{Min}_{x \in X, y} & f(x, y) \\ \text{s.t.} & h(x, y) \leq 0 \\ & y \text{ solves } \begin{array}{ll} \text{Min}_y & g(x, y) \\ \text{s.t.} & k(x, y) \leq 0, \end{array} \end{array} \quad (23)$$

where

- $x \in \mathbb{R}^n$ are the upper-level variables,
- $y \in \mathbb{R}^m$ are the lower-level variables,
- $f : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}$ is the upper-level objective function,
- $g : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}$ is the lower-level objective function,
- $h : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^u$ are the upper-level constraints, and
- $k : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^l$ are the lower-level constraints.

Note that the upper-level constraints do not bind the lower-level decision maker.

This problem can be implemented with EMP as follows:

```
Sets i, j ;
Variables x(i), objout, y(i), objin;
Equations deff(x,y), defg(x,y), defh(x,y), defk(x,y);

* Definitions of equations are omitted

Model bilevel / deff, defg, defH, defw /;

$onecho > "%emp.info%"
bilevel x
min objin y defg defk
$offecho

solve bilevel using EMP minimizing objout ;
```

Note that the variables and equations of the program are defined in GAMS in the usual way. The special bilevel structure of the model is specified in the [EMP annotations](#). The [EMP keyword](#) `bilevel` indicates that this is a bilevel problem. The name and direction of the leader's objective variable is taken from the solve statement, but the other variables owned by the leader are listed after the `bilevel` keyword. The lower-level problem is specified next via the EMP keyword `min`, followed by the follower's objective variable `objin`. The other variables and the equations of the lower-level problem are listed next. Observe that this is exactly the same syntax that we introduced [above](#) for specifying optimization problems in the context of equilibrium problems.

The EMP tool reformulates the bilevel problem as a Mathematical Program with Equilibrium Constraints (MPEC) and passes this on to a subsolver (e.g. NLPEC or KNITRO). The reformulation is obtained by replacing the lower-level optimization problem by its KKT conditions, resulting in the following problem:

$$\begin{aligned}
 &\text{Min}_{x \in X, y, \lambda} && f(x, y) \\
 &\text{s.t.} && h(x, y) \leq 0 \\
 & && k(x, y) \leq 0 \\
 & && \lambda_i \leq 0, && i = 1, \dots, l \\
 & && \lambda_i k_i(x, y) = 0, && i = 1, \dots, l \\
 & && \nabla_y \mathcal{L}(x, y, \lambda) = 0,
 \end{aligned} \tag{24}$$

where

$$\mathcal{L}(x, y, \lambda) = g(x, y) + \sum_{i=1}^l \lambda_i k_i(x, y) \tag{4.25}$$

is the Lagrangian function associated with the lower-level problem.

Note, however, that this reformulation is potentially problematic. KKT conditions require theoretical assumptions (like convexity) to be necessary and sufficient for *local optimality*. There may be cases where the lower level problem has multiple local solutions, but the modeler is interested in the *global* solution. Hence the reformulation above may not lead to the global solution, even if a global subsolver is used within the solver NLPEC.

Observe that there are two variations to problem (23) that the EMP framework is equipped to handle: the lower-level problem may be a ["variational inequality"](#) instead of an optimization problem, and there may be multiple lower-level problems (optimizing and/or VI) each behaving in a Nash manner. Examples follow in sections [Bilevel Programs with EMP: A VI as Follower](#) and [Bilevel Programs with EMP: Multiple Followers](#) respectively.

4.47.9.2 Bilevel Programs with EMP: A Simple Example

To illustrate, we use model [\[BARD851\]](#) from the GAMS EMP Library. Mathematically, the problem is

$$\begin{aligned}
 &\text{Min}_{x, y_1, y_2} && (x-1)^2 + 2y_1^2 - 2x \\
 & && x \geq 0 \\
 &\text{s.t.} && (y_1, y_2) \text{ solve} && \text{Min}_{y_1, y_2} && (2y_1 - 4)^2 + (2y_2 - 1)^2 + xy_1 \\
 & && && \text{s.t.} && 4x + 5y_1 + 4x_2 \leq 12 \\
 & && && && -4x + 5y_1 + 4x_2 \leq -4 \\
 & && && && 4x - 4y_1 + 5x_2 \leq 4 \\
 & && && && -4x + 4y_1 + 4x_2 \leq -4 \\
 & && && && y_1, y_2 \geq 0
 \end{aligned} \tag{25}$$

Note that this problem does not have any upper-level constraints. The GAMS code follows.

```

Positive Variables x, y1, y2;
Variables          objout, objin;

Equations defout, defin, e1, e2, e3, e4;

defout..  objout =e= sqr(x-1) + 2*sqr(y1) - 2*x;
defin..   objin  =e= sqr(2*y1-4) + sqr(2*y2-1) + x*y1;

e1..      4*x + 5*y1 + 4*y2 =l= 12;
e2..      - 4*x - 5*y1 + 4*y2 =l= -4;
e3..      4*x - 4*y1 + 5*y2 =l=  4;
e4..      - 4*x + 4*y1 + 5*y2 =l=  4;

Model bard / all /;

$echo bilevel x min objin y1 y2 defin e1 e2 e3 e4 > "%emp.info%"

solve bard use emp min objout;

```

The leader minimizes the variable `objout`, as specified in the solve statement. The [EMP annotations](#) specify the rest of the bilevel structure: the variable `x` belongs to the upper-level problem, and there is one lower-level agent or problem with `objin` minimized over the variables `y1` and `y2` subject to the constraints or equations `defin`, `e1`, `e2`, `e3` and `e4`.

Alternatively, we could write the EMP annotations as:

```
$echo bilevel x min objin * defin e1 e2 e3 e4 > "%emp.info%"
```

Here the lower-level variables are not listed: instead, the '*' indicates that all variables in the GAMS model not explicitly assigned to any agent are to be assigned to the follower.

The [EMP Summary](#) produced by JAMS gives the number of followers in the bilevel program:

```

--- EMP Summary
  Bilevel Followers   = 1

```

The GAMS EMP Library contains other bilevel examples, including several models `bard*`, the engineering models `[CCMG74]` and `[CCMG153]`, and the simple nonconvex model `[MIRRLess]`. The models `[JOINTC1]` and `[JOINTC2]` illustrate the interplay of the decision variables of the upper-level and lower-level problems.

4.47.9.3 Bilevel Programs with EMP: A VI as Follower

If the lower-level problem is a [variational inequality](#), problem (23) will take the following form:

$$\begin{aligned}
 &\text{Min}_{x,y} && f(x,y) \\
 &\text{s.t.} && h(x,y) \leq 0 \\
 &&& y \text{ solves } VI(F, K(x)),
 \end{aligned} \tag{26}$$

where

- $x \in \mathbb{R}^n$ are upper-level variables and $y \in \mathbb{R}^m$ are lower-level variables, and
- $K(x) \subseteq \mathbb{R}^m$ is a closed convex set, parametrized by x .

Consider the following simple example adapted from [MULTMPEC]:

$$\begin{aligned}
 &\text{Min}_{w,z} && z \\
 &\text{s.t.} && e^z + w = 2 \\
 &&& z \geq 1 \\
 &&& w \text{ solves the } VI(F, K), \text{ where } K = \mathbb{R} \text{ and } F = w + z + 3
 \end{aligned} \tag{27}$$

This bilevel problem can be modeled with EMP as follows:

```

variables w, z;
equations h, F;

h.. exp(z) + w =e= 2;
F.. w + z =n= -3;

z.lo = 1;

model bpvi / h, F /;

$onecho > %emp.info%
bilevel z
vi F w
$offecho

solve bpvi using emp min z;

```

Note that in the [EMP annotations](#) the lower-level problem is specified as a VI with the VI function **F** and the corresponding variable **w**: for details see section [EMP Syntax for Variational Inequalities](#). The count of VI functions is indicated in the [EMP Summary](#):

```

--- EMP Summary
...
VI Functions          = 1
...
Bilevel Followers     = 1

```

4.47.9.4 Bilevel Programs with EMP: Multiple Followers

The EMP framework allows multiple followers in a bilevel program. Taking the leader decisions as fixed, these followers behave as the agents in a [Nash equilibrium](#). Consider the engineering example [CCMG71] from the GAMS EMP Library. In this bilevel program there are two followers, both solving minimization problems, specified in the [EMP annotations](#) as follows:

```

...
$onecho > %emp.info%
bilevel x1 x2 x3 x4
  min h1 u1 u2 u3 u4 defh1 e1
  min h2 v1 v2 v3 v4 defh2 e2
$offecho
...

```

The variables `x1`, `x2`, `x3` and `x4` are owned or controlled by the leader. The first follower minimizes the variable `h1` over the variables `u1`, `u2`, `u3` and `u4` subject to the constraint/equation `e1`. The second follower is defined in a similar way. More details on how to specify optimization subproblems in the EMP annotations are given in section [EMP Syntax for Equilibrium Problems](#).

Observe that in the EMP annotations of the actual model [CCMG71] the following shorthand notation is used:

```
...
$onecho > %emp.info%
bilevel x1 x2 x3 x4
min h1 * defh1 e1
min h2 * defh2 e2
$offecho
...
```

The symbol `'*` in the problem of the first follower indicates that this agent will optimize over all variables appearing in equations `defh1` and `e1` (i.e. the equations it controls) that are not claimed by another agent. In this case, the respective variables are `u1`, `u2`, `u3` and `u4`. N.B.: in this example, if a variable appears in the equations for both followers the problem structure is not well defined and an error will result. To avoid confusion and promote clarity, we recommend that modelers explicitly list all the variables in each agent's problem, as shown in the first version of the EMP annotations above.

The number of followers is indicated in the [EMP Summary](#):

```
--- EMP Summary
...
Bilevel Followers    = 2
```

The **GAMS EMP Library** contains several bilevel problems with several followers, e.g. the well-known transportation model with a variable demand function cast as a bilevel problem with one optimization follower and one VI follower [TRANSBP], a simple example with two VI followers [MULTMPEC], and the spatial equilibrium Stackelberg model [HARK-STACK].

4.47.9.5 EMP Syntax for Bilevel Programs

The general syntax that EMP provides to specify bilevel programs in the [EMP annotations](#) file `emp.info` is as follows:

```
Bilevel {var}
{MAX|MIN obj {var|*} {[ -] equ}}
{VI {var|*} {[ -] equ var} {[ -] equ}}
{Dualvar {var [ -] equ}}
```

A bilevel program is declared with the [EMP keyword](#) `bilevel`, followed by the decision variables of the upper-level problem. The other specifications refer to the lower-level problems. These lower-level followers are optional, but at least one follower has to be specified. Optimization problems are defined using the EMP keyword `max` or `min` followed by the objective variable `obj` and the decision variables and the equations that implement the constraints of the problem. Variational inequalities are introduced with the EMP keyword `vi`: details of the specification are given in section [EMP Syntax for Variational Inequalities](#). The `dualvar` keyword is used in the same way as it is for [equilibrium problems](#).

Note

While the EMP framework allows the symbol `'*` to be used to specify an automatically-created list of variables, we recommend against using the `'*` in the annotations file. Instead, list all variables explicitly to make the structure of the model clear and unambiguous to both human and machine readers of the EMP info file.

4.47.10 Disjunctive Programming

Disjunctive programming is an alternative modeling approach to mixed integer programming. Both mathematical programs model optimization problems that involve discrete and continuous variables. The advantage of disjunctive programming is that it retains and exploits the inherent logic structure of problems and thus reduces the combinatorics and improves the relaxations by using Boolean variables and disjunction definitions for modeling discrete choices.

Disjunctive programs have many applications, including ordering of tasks in a production process, organizing complex projects in a time saving manner and choosing the optimal route in a circuit.

In this section we first present the [mathematical formulation](#) of Generalized Disjunctive Programs (GDPs) and then demonstrate how disjunctive programs are implemented with GAMS EMP using two simple examples. Note that both examples are adapted from the [LogMIP 2.0 User's Manual](#). At the end of the section we introduce and discuss the syntax for [EMP annotations for disjunctive programs](#).

For information on the development of disjunctive programming in GAMS EMP and its connection to the solver LogMIP, see the respective section in the solver manual of the solver JAMS.

4.47.10.1 Generalized Disjunctive Programs (GDPs)

A GDP has Boolean and continuous variables, algebraic constraints that need to be satisfied regardless of the discrete choices, disjunctions that represent the discrete choices, and logic propositions that contain the logic relationships between the Boolean variables. Mathematically, the general structure of a GDP may be expressed as follows:

$$\begin{array}{ll}
 \text{Min} & f(x) & \text{Objective Function} \\
 \text{s.t.} & g(x) \leq 0 & \text{Algebraic Constraints} \\
 & \bigvee_{i \in D_k} \left[Y_{ik} \right], k \in K & \text{Disjunctions} \\
 & \Omega(Y) = \text{True} & \text{Logic Propositions} \\
 & L \leq x \leq U, x \in \mathbb{R}^n, & \text{Continuous Variables} \\
 & Y_{ik} \in \{\text{True}, \text{False}\} & \text{Boolean Variables}
 \end{array} \tag{28}$$

where:

- $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is a function, x is a vector of continuous variables with bounds L and U .
- $g : \mathbb{R}^n \rightarrow \mathbb{R}^l$ represents the set of global constraints.
- Each disjunction $k \in K$ is composed of a number of terms $i \in D_k$ that are connected by the Boolean operator OR ($\bigvee$).
- Each term $i \in D_k$ consists of a Boolean variable Y_{ik} and a set of inequalities $r_{ik}(x) \leq 0$, $r_{ik} : \mathbb{R}^n \rightarrow \mathbb{R}^j$. If Y_{ik} is true, then $r_{ik}(x) \leq 0$ is enforced, otherwise these constraints are ignored.
- $\Omega(Y) = \text{True}$ are logic propositions for the Boolean variables Y_{ik} expressed in the Conjunctive Normal Form $\Omega(Y) = \bigwedge_{t=1,2,\dots,T} [\bigvee_{Y_{jk} \in R_t} (Y_{jk}) \bigvee_{Y_{jk} \in Q_t} (\neg Y_{jk})]$, where for each clause $t \in 1, \dots, T$, R_t is the subset of Boolean variables that are non-negated and Q_t is the subset of Boolean variables that are negated.

N.B.: we assume that each disjunction is an exclusive-or, so that for each k exactly one variable Y_{ik} is true. Put another way, we assume the logic constraints $\bigvee_{i \in D_k} Y_{ik}$ are contained in $\Omega(Y) = \text{True}$.

There are three cases of disjunctive programs: the functions f , g and r are linear, some of them are nonlinear, but convex, and some of them are nonlinear and nonconvex. Note that currently GAMS EMP facilitates modeling only the first two cases.

4.47.10.2 Disjunctive Programming with EMP: Example with No Algebraic Constraints

Consider the following simple example, that has no algebraic constraints which must be satisfied regardless of the disjunctive choices:

$$\begin{array}{ll}
 \text{Minimize} & c + 2x_1 + x_2 \\
 \text{subject to} & \\
 & \left[\begin{array}{c} Y_1 \\ -x_1 + x_2 + 2 \leq 0 \\ c \leq 5 \end{array} \right] \vee \left[\begin{array}{c} Y_2 \\ 2 - x_2 \leq 0 \\ c \leq 7 \end{array} \right] \\
 & \left[\begin{array}{c} Y_3 \\ x_1 - x_2 \leq 0 \end{array} \right] \vee \left[\begin{array}{c} \neg Y_3 \\ x_1 \leq 1 \end{array} \right] \\
 & Y_1 \wedge \neg Y_2 \Rightarrow \neg Y_3 \\
 & Y_2 \Rightarrow \neg Y_3 \\
 & Y_3 \Rightarrow \neg Y_2 \\
 & 0 \leq x_1 \leq 5 \\
 & 0 \leq x_2 \leq 5 \\
 & c \geq 0 \\
 & Y_j \in \{\text{True}, \text{False}\}, j = 1, 2, 3
 \end{array}
 \quad \begin{array}{l}
 \text{Objective Function} \\
 \\
 \text{Disjunctions} \\
 \\
 \text{Logic Propositions} \\
 \\
 \text{Continuous Variables} \\
 \\
 \text{Boolean Variables}
 \end{array}
 \quad (29)$$

Observe that there are two disjunctions, each with two terms. In the first disjunction, each term is governed by a different Boolean variable: the first term is active if Y_1 is true and the second term is active if Y_2 is true. In the second disjunction, both terms are governed by the Boolean variable Y_3 : the first term applies if Y_3 is true and the second term applies if Y_3 is false.

Note that the logic propositions imply that if Y_1 is true and Y_2 is false, then Y_3 must be false, and that Y_2 and Y_3 cannot both be true.

This example can be implemented in GAMS EMP as follows:

```

Set i / 1*2 /
    j / 1*3 /;

Positive Variables x(i), c;
Variable          z;
Binary Variables  y(j);

x.up(i) = 5;
c.up    = 7;

Equations Obj, Eq1, Eq2, Eq3, Eq4, Eq5, Eq6;

Obj..    z =e= c + 2*x('1') + x('2');

* Equations for Disjunctions
Eq1..    x('2') - x('1') =l= - 2;
Eq2..    c =l= 5;
Eq3..    x('2') =g= 2;
Eq4..    c =l= 7;
Eq5..    x('1') - x('2') =l= 1 ;
Eq6..    x('1') =l= 1;

```

```

* Equations for Logic Propositions
Logic Equations  LEq1, LEq2, LEq3;

LEq1..  y('1') and not y('2') -> not y('3');
LEq2..  y('2') -> not y('3');
LEq3..  y('3') -> not y('2');

Model small1 / all /;

File emp / '%emp.info%' /;
put emp;
$onput
disjunction y('1') Eq1 Eq2 elseif y('2') Eq3 Eq4
disjunction y('3') Eq5 else Eq6
$offput
putclose;

Option optcr = 0.0;

solve small1 using EMP minimize z;

```

Note that in this model the Boolean variables Y_j are implemented as GAMS binary variables, the inequalities in the terms of the disjunctions are formulated as [GAMS equations](#), and the logic propositions are expressed as [GAMS logic equations](#). The disjunctive structure of the model is specified in the [EMP annotations](#) file `emp.info`. This file contains two lines (one per disjunction), each starting with the [EMP keyword](#) `disjunction` and specifying the structure and content of its disjunction. In the first line or disjunction, the binary variable `y('1')` that governs the first term is followed by the two equations contained in this term. The [EMP keyword](#) `elseif` denotes the start of a new term, here governed by the binary variable `y('2')` listed next and containing the two equations `Eq3` and `Eq4`. Similarly, in the second line, the binary variable `y('3')` that governs the first term of the second disjunction is followed by the equation `Eq5` contained in that term. As the binary variable governing the second term is just the negation of `y('3')`, the keyword `else` is enough to specify this and is followed by the equation `Eq6` of the second term.

Note

Much more complex logical constructs for disjunctions are possible. For details, see section [EMP Syntax for Disjunctive Programming](#) below.

Finally, note that the model type in the solve statement is `EMP`.

Given the annotations in the file `emp.info`, the solver JAMS reformulates the model as a MIP (Mixed Integer Programming) model and passes it to a subsolver. By default, the convex hull relaxation is used for the reformulation, but users may choose reformulations that use big M or indicator constraints: see section [EMP Syntax for Disjunctive Programming](#) for details.

Observe that the listing file will contain some additional information if the model type `EMP` is used. The *EMP Summary* and the *Disjunction Summary* may be particularly useful. The respective listings for our example model follow:

```

--- EMP Summary
    Logical Constraints = 3
    Disjunctions       = 2
...
...
--- Disjunction Summary
    Disjunction 1 Term 2 is active
    Disjunction 2 Term 2 is active

```

Note that the EMP summary lists the number of logic constraints and disjunctions and the disjunction summary reports which terms of the disjunctions are active in the optimal solution.

4.47.10.3 Disjunctive Programming with EMP: Example with No Logic Propositions

Consider the following simple example:

$$\begin{array}{ll}
 \text{Min} & t \\
 \text{s.t.} & t \geq x_A + 8 \\
 & t \geq x_B + 5 \\
 & t \geq x_C + 6 \\
 \\
 & \left[\begin{array}{c} Y_1 \\ x_A - x_C + 5 \leq 0 \end{array} \right] \vee \left[\begin{array}{c} \neg Y_1 \\ x_C - x_A + 2 \leq 0 \end{array} \right] \\
 & \left[\begin{array}{c} Y_2 \\ x_B - x_C + 1 \leq 0 \end{array} \right] \vee \left[\begin{array}{c} \neg Y_2 \\ x_C - x_B + 6 \leq 0 \end{array} \right] \\
 & \left[\begin{array}{c} Y_3 \\ x_A - x_B + 5 \leq 0 \end{array} \right] \vee \left[\begin{array}{c} \neg Y_3 \\ x_B - x_A \leq 0 \end{array} \right] \\
 \\
 & t, x_A, x_B, x_C \geq 0 \\
 & Y_j \in \{\text{True}, \text{False}\}, j = 1, 2, 3
 \end{array}
 \quad \begin{array}{l}
 \text{Objective Function} \\
 \text{Algebraic Constraints} \\
 \\ \\ \\ \\ \\ \\ \\
 \text{Disjunctions} \\
 \\ \\ \\ \\ \\ \\
 \text{Continuous Variables} \\
 \text{Boolean Variables}
 \end{array}
 \tag{30}$$

As this example has no logic propositions, the binary variables would not appear in any equations of a GAMS formulation like the one above. As a result, the binary variables would not be part of the model and any EMP annotations file that mentions these variables would be rejected by the EMP solver. To avoid this problem, we can introduce a dummy equation and include it in the EMP model: this ensures that the binary variables will be part of the GAMS model. The respective code follows:

```

set i / A, B, C /
    j / 1*3 /
;
positive variables x(i), t;
binary variables y(j);
variable          z;

equations obj, alg1, alg2, alg3,
           d1t1, d1t2, d2t1, d2t2, d3t1, d3t2
           dummy;

obj.. z =e= t;

* common algebraic equations
alg1.. t =g= x('A') + 8;
alg2.. t =g= x('B') + 5;
alg3.. t =g= x('C') + 6;

* equations for disjunctions
d1t1.. x('A') - x('C') + 5 =l= 0;
d1t2.. x('C') - x('A') + 2 =l= 0;
d2t1.. x('B') - x('C') + 1 =l= 0;
d2t2.. x('C') - x('B') + 6 =l= 0;
d3t1.. x('A') - x('C') + 5 =l= 0;
d3t2.. x('B') - x('C')      =l= 0;

* dummy equation
dummy.. sum(j, y(j)) =g= 0;

```

```

model small2 / all /;
file emp / '%emp.info%' /;

putclose emp
"disjunction y('1') d1t1 else d1t2" /
"disjunction y('2') d2t1 else d2t2" /
"disjunction y('3') d3t1 else d3t2" /
;
option optcr = 0.0;
solve small2 using EMP minimize z;

```

Apart from the dummy equation, this formulation is very similar to the formulation in the first example [above](#).

EMP also supports an alternative formulation for models that have no logic equations, a formulation using *implicit default binary variables*. These variables are denoted in the EMP annotations with the star symbol '*', which is internally replaced by a default binary variable. Note that this alternative model does not contain any explicit binary variables $Y(j)$ and hence the dummy equation may be omitted, as in the following GAMS code which can be added to the model above:

```

model small3 'no dummy equation needed' / small2 - dummy /;

putclose emp
"disjunction * d1t1 else d1t2" /
"disjunction * d2t1 else d2t2" /
"disjunction * d3t1 else d3t2" /
;
solve small3 using EMP minimize z;

```

4.47.10.4 EMP Syntax for Disjunctive Programming

The general syntax that EMP provides to write disjunctions to the [EMP annotations](#) file `emp.info` is as follows:

```

Disjunction [chull [chull eps] | bigM [big M value] | indic]
            [NOT] var|* [NOT] {equ} {ELSEIF [NOT] var|* [NOT] {equ}} [ELSE [NOT] {equ}]

```

The [EMP keyword](#) `Disjunction` is mandatory, it indicates that what follows is a disjunction. The three constructs that follow are optional and relate to the three possible reformulations: convex hull (`chull`), big M method (`bigM`) or indicator constraints (`indic`). Note that in the sequencing model `[SEQUENCE]` all three options are implemented. Note further, that currently, indicator constraints can only be handled by the solvers CPLEX, SCIP and XPRESS.

Note

- By default, the convex hull reformulation method is used.
- A different reformulation method may be used for each disjunction.

Observe that for the convex hull reformulation, the value of the parameter `epsilon` may optionally be specified. This parameter is an upper bound to check for constraint satisfaction, the default value is 0.0001.

Note that for the big M method, the value of M may optionally be specified. The value of M should be large enough to relax the constraint, but it should not be too large, to avoid infeasible solutions. The default value is 10000.

Following the EMP keyword `disjunction`, the first mandatory entry is a specification of the variable that governs the disjunction: `[NOT] var|*`. This may be either a binary variable, a negated binary variable or the symbol '*', that is internally replaced by default binary variables. For an example and more details on the symbol '*' in this context, see section [Disjunctive Programming with EMP: Example with No Logic Propositions](#). Further, `{equ}` denotes a set of GAMS equation names that must be satisfied if the first disjunction term is selected. The remainder of the syntax is self-explanatory.

Alternatively, the following syntax may be used:

```
Default [chull [chull eps] | bigM [big M value] | indic]
Disjunction [NOT] var|* [NOT] {equ} {ELSEIF [NOT] var|* [NOT] {equ}} [ELSE [NOT] {equ}]
```

Note that the first line is optional and serves to specify the reformulation method. The second line is identical to the first formulation of the general syntax where the specification of the reformulation method is omitted. Some users find this alternative syntax clearer, since the specification of the reformulation method and the disjunction are separated.

In addition to the sequencing model `[SEQUENCE]` that was already mentioned, the GAMS EMP Library has two other models for disjunctive programming: the manufacturing problem `[FOODEMP]` and the job scheduling problem `[MAKESPAN]`

4.47.11 Stochastic Programming

Stochastic programs are mathematical programs that involve data that is not known with certainty. Deterministic programs are formulated with fixed parameters, whereas real world problems frequently include some uncertain parameters. Often these uncertain parameters follow a probability distribution that is known or can be estimated. Thus stochastic programs approximate unknown data by probability distributions. The goal is to find some policy that is feasible for all (or almost all) the possible data instances and that maximizes the expectation of some function of the decision variables and the random variables. The EMP framework includes an extension for stochastic programming that allows users to model various stochastic problems as deterministic models, while information about the stochastic structure of the problem, like probability distributions for some data, is specified in the [EMP annotations](#). Thus formulating stochastic programs becomes straightforward.

In the remainder of this chapter we discuss the stochastic programming extension of GAMS EMP. We introduce the basics of stochastic programming with EMP using a [two-stage stochastic model](#) and then show how the logic can be extended to [multi-stage stochastic problems](#). In most stochastic problems the expected value of the objective is optimized. The EMP framework facilitates optimizing two additional [risk measures](#): [Value at Risk \(VaR\)](#) and [Conditional Value at Risk \(CVaR\)](#). These alternative risk measures are discussed next. Another type of stochastic programming includes constraints that hold only with certain probabilities. These constraints are called [chance constraints](#) (or *probabilistic constraints*), they are the topic of the last section on stochastic programming. At the end of each section we give an overview of the EMP annotations that are specific to each topic: [stochastic programming with recourse](#), [additional risk measures](#), and [chance constraints](#). A summary of all [EMP keywords for stochastic programming](#) is given in section [GAMS EMP Keywords for Stochastic Programming](#).

4.47.11.1 Stochastic Programming with Recourse

One way to think about stochastic problems is to require the decision maker to make a decision now and then to minimize the expected costs of the consequences of that decision. This paradigm is called the *recourse* model. The simplest form of the recourse model has two stages: a decision is made in the first stage, then the realization of the uncertain parameters is revealed at the start of the second stage and recourse actions can be taken given this new information. This simple model can be extended to include more stages. In a *multistage* problem, a decision is made in the first stage, then some uncertainty is resolved in the second stage and another decision is made based on this new knowledge, then some other uncertainty is resolved and so on. The objective is to minimize the expected costs of the decisions in all stages.

This section is organized as follows. We start with a [mathematical formulation](#) of the two-stage stochastic problem with recourse, then show how such problems can be modeled with EMP using a [simple example](#). The uncertain data in this first example follows a discrete distribution, there are just three different scenarios. [Continuous distributions](#) are more complex to model. Mostly, they are approximated to discrete distributions by [sampling](#), which is discussed next. The second example illustrates how the modeling approach for a simple two-stage problem can be extended to solve a [multi-stage problem](#). We conclude this section with a description of the [EMP annotations for stochastic programs with recourse](#).

4.47.11.1.1 Two-Stage Stochastic Programs: Mathematical Formulation The simplest form of a stochastic program is the two-stage stochastic linear program with recourse. In mathematical terms it is defined as follows.

Let $x \in \mathbb{R}^n$ and $y \in \mathbb{R}^m$ be two variables and let the set of all realizations of the unknown data be given by Ω , $\Omega = \{\omega_1, \dots, \omega_S\} \subseteq \mathbb{R}^r$, where r is the number of the random variables representing the uncertain parameters. Then the stochastic program is given by

$$\begin{aligned} \text{Min}_x \quad & z = c^T x + \mathbb{E}[Q(x, \omega)] \\ \text{s.t.} \quad & Ax = b, \quad x \geq 0, \\ \text{where} \quad & Q(x, \omega) = \text{Min}_y \quad q_\omega^T y(\omega) \\ \text{s.t.} \quad & T_\omega x + W_\omega y(\omega) = h_\omega, \quad y(\omega) \geq 0, \quad \forall \omega \in \Omega. \end{aligned} \tag{31}$$

The first two lines define the *first-stage* problem and the last two lines define the *second-stage* problem. In the first stage, x is the decision variable, c^T represents the cost coefficients of the objective function and $\mathbb{E}[Q(x, \omega)]$ denotes the expected value of the optimal solution of the second stage problem. In addition, A denotes the coefficients and b the right-hand side of the first stage constraints. In the second stage, y is the decision variable, T represents the transition matrix, W the recourse matrix (cost of recourse) and h the right-hand side of the second stage constraints. Note that all parameters and the decision variable of the second stage are dependent on the specific realization of the stochastic data ω . The objective variable z is also a random variable, since it is a function of ω . As a random variable cannot be optimized, stochastic solvers automatically optimize the *expected value* of the objective variable z . Note that the EMP framework allows other risk measures to be optimized in addition to the expected value. This is discussed [below](#).

In the first stage, a decision has to be made before the realization of the uncertain data is clear. The optimal solution of the first stage is fixed and only then it will become known which values the uncertain parameters will take. Given the fixed solution of the first stage and the new data, recourse action can be taken in the second stage and the optimal solution determined. Each possible realization of the uncertain data is represented by $\omega_s \in \Omega$ and is called a *scenario*. The objective is to find a feasible solution x that minimizes the total cost, namely the sum of the first-stage costs and the expected second-stage costs.

One of the most common methods to solve a two-stage stochastic LP is to build and solve the *deterministic equivalent*. Assume that the uncertain parameters follow a (finite) discrete distribution and that each scenario ω_s occurs with probability $P(\omega_s) = p_s$ for all $s = 1, \dots, S$ and $\sum_s p_s = 1$. Thus $\mathbb{E}[Q(x, \omega)] =$

$\sum_s p_s q^T y_s$, where y_s denotes the optimal second-stage decision for the scenario ω_s . Then the deterministic equivalent can be expressed as follows:

$$\begin{array}{rclcl}
 c^T x & + & p_1 q^T y_1 & + & p_2 q^T y_2 & + & \dots & + & p_S q^T y_S \\
 \text{s.t.} & & & & & & & & \\
 Ax & & & & & & & & = & b \\
 T_1 x & + & W_1 y_1 & & & & & & = & h_1 \\
 T_2 x & & & + & W_2 y_2 & & & & = & h_2 \\
 \vdots & & & + & & & \ddots & & \vdots \\
 T_S x & & & & & & & + & W_S y_S & = & h_S \\
 x \in \mathbb{R}^n & & y_1 \in \mathbb{R}^m & & y_2 \in \mathbb{R}^m & & & & y_S \in \mathbb{R}^m
 \end{array} \tag{32}$$

Note that for stochastic linear programs the deterministic equivalent is just another (potentially very large) linear program.

A GAMS EMP stochastic model has three parts: the *core model*, [EMP annotations](#) and the *dictionary*, which contains output-handling information. The *core model* is a deterministic model, where the uncertain data is given as fixed parameters. Often, the expected value of the probability distribution is chosen.

The *annotations* contain information about the stochastic features of the model: a specification of the random variables and their distributions, details about the stages and possibly directions concerning sampling.

Given the probability distributions of the random variables, the solvers of stochastic programming models create various scenarios and evaluate them. In the *dictionary* users specify which results from each scenario are to be stored in standard parameters in order to be accessed later. These three parts of a GAMS EMP stochastic model will become much clearer as they are illustrated in the next subsection.

4.47.11.1.2 A Simple Example: The News Vendor Problem Consider the following simple example adapted from the news vendor model [NBSIMPLE]. A news vendor has to decide early in the morning how many newspapers to buy from a distributor on a particular day in order to sell them to his customers. He knows from experience that the demand will be 45 in 70% of all cases, 40 with a probability of 20% and 50 with a probability of 10%. If the demand is less than the number of newspapers he bought in the morning, the left-over newspapers will be stored in an inventory at a cost per unit. If the demand exceeds his expectations and there are more customers than newspapers, then he will have to pay a penalty. He aims to maximize his profit by selling the newspapers at a higher price than he has bought them. Mathematically, the problem can be expressed as follows:

$$\begin{array}{ll}
 \text{Max}_x & Z(x, D) = -cx + \mathbb{E}[Q(x, D)], \quad x \geq 0, \\
 \text{where } Q(x, D) = & \text{Max}_{s, i, l} \quad vs_D - hi_D - pl_D \\
 \text{s.t.} & x - s_D - i_D = 0 \\
 & s_D + l_D = D, \quad s_D, i_D, l_D \geq 0
 \end{array} \tag{33}$$

where

- the variable x denotes the number of newspaper bought in the morning,
- c is the cost per newspaper,
- D is a random variable that denotes the uncertain demand; the set of all realizations of D is given by $\Omega = \{d_1, d_2, d_3\}$, with $d_1 = 45$, $d_2 = 40$ and $d_3 = 50$, and the respective probabilities $p_1 = 0.7$, $p_2 = 0.2$ and $p_3 = 0.1$,
- the variable s denotes the number of newspapers that are sold,

- v is the selling price,
- the variable i denotes the number of newspapers that could not be sold, in case the demand turned out to be less than expected,
- h is the holding cost in the inventory per unit,
- the variable l denotes the unsatisfied demand, in case the demand turned out to be higher than expected,
- p is the penalty per unit of unsatisfied demand.

Note that x is the first-stage decision variable and the variables s , i and l are the second-stage decision variables. The second-stage decision variables are dependent on D . An overview of the stages in this problem is given in the following table:

1st Stage Decision Variable	2nd Stage Decision Variable; $\Omega = \{d_1, d_2, d_3\}$	Probabilities
x	$y_{d_1} = (s_{d_1}, l_{d_1}, i_{d_1})$	Scenario 1: $p_1 = 0.7$
x	$y_{d_2} = (s_{d_2}, l_{d_2}, i_{d_2})$	Scenario 2: $p_2 = 0.2$
x	$y_{d_3} = (s_{d_3}, l_{d_3}, i_{d_3})$	Scenario 3: $p_3 = 0.1$

Table 3: Two stages in the News Vendor Problem

Observe that the decision x has to be made before the realization of the demand D is known. Given the uncertainty of the demand, we aim to maximize the *expected value* of the profit, denoted by $\mathbb{E}[Z(x, D)]$. The expected value of the profit is the profit *on average*. Note that as we have a finite number of scenarios and their probabilities are known, the expected value of the profit $\mathbb{E}[Z(x, D)]$ can be expressed as a weighted sum:

$$\mathbb{E}[Z(x, D)] = -cx + \mathbb{E}[Q(x, D)] - cx + \sum_{k=1}^3 p_k Q(x, d_k). \quad (34)$$

Note that in this example there are no first stage equations $Ax = b$.

The *core model* is the first part of the respective GAMS EMP model:

```

Variable z      "profit";
Positive Variables
    x      "units bought"
    i      "inventory"
    l      "lost sales"
    s      "units sold";

Scalars c      "purchase costs per unit"      / 30 /
p      "penalty shortage cost per unit"      / 5 /
h      "holding cost per leftover unit"      / 10 /
v      "revenue per unit sold"              / 60 /
d      "demand, random parameter"          / 45 /;

Equations profit "profit to be maximized"
row1  "demand = UnitsSold + LostSales"
row2  "inventory = UnitsBought - UnitsSold";

```

```

profit..  z =e= v*s - c*x - h*i - p*l;
row1..    d =e= s + l;
row2..    i =e= x - s;

Model nv / all /;

```

Observe that the model is defined in the usual way. In particular, the demand **d** is modeled as a fixed parameter.

The [EMP annotations](#) are the second part. Here we specify the stochastic structure:

```

File emp / '%emp.info%' /;
put emp '* problem %gams.i%' /;
$onput
randvar d discrete 0.7 45 0.2 40 0.1 50
stage 2 i l s d
stage 2 Row1 Row2
$offput
putclose emp;

```

First, we define the parameter **d** to be a random variable using the [EMP keyword](#) **randvar** and we specify the probability distribution. The EMP keyword **discrete** indicates that **d** follows a discrete distribution: with probability 0.7 it takes a value of 45, with probability 0.2 it takes a value of 40, and with probability 0.1 it takes a value of 50.

Note

If the sum of the probabilities of a discrete distribution is smaller or larger than 1, the EMP framework will automatically normalize the probabilities so that the sum equals 1 and a corresponding remark will appear in the log and listing file.

Observe that continuous distributions are also possible, see section [Random Variables with Continuous Distributions](#) below for details.

Secondly, we specify which variables and equations belong to stage 2 using the EMP keyword **stage**. Note that the variables and equations that are not listed in the annotations are automatically assigned to a stage, by default stage 1. Only the objective variable (in this case **Z**) and the objective equation (**profit**) are assigned to the highest stage specified instead (stage 2 in this example). Observe that **Z** is in fact a random variable since it is a function of the random variable **D**. As such it cannot be optimized directly, EMP implicitly maximizes the *expected value* of **Z**. This might lead to some confusion since the expected value of **Z** belongs to **stage 1**. We show in section [Expected Value Revisited](#) how to specify more clearly the fact that we are maximizing $\mathbb{E}(Z)$.

All keywords that can be used in EMP annotations in the context of stochastic programming are introduced in subsequent examples and they are summarized in section [GAMS EMP Keywords for Stochastic Programming](#).

The dictionary with output-handling information and the solve statement are the third part of the model. After solving a stochastic programming model, only the solution of the expected value problem may be accessed via the regular **.l** and **.m** fields. The results of the scenarios that were created and evaluated by the stochastic solvers may be stored in standard parameters in the following way:

```

Set scen          "scenarios" / s1*s3 /;
Parameter
  s_d(scen)       "demand realization by scenario"
  s_x(scen)       "units bought by scenario"
  s_s(scen)       "units sold by scenario"
  s_rep(scen,*)   "scenario probability"    / #scen.prob 0/;

Set dict / scen .scenario.''
  d   .randvar .s_d
  s   .level   .s_s
  x   .level   .s_x
  ''  .opt     .s_rep /;

solve nv max z use EMP scenario dict;
display s_d, s_x, s_s, s_rep;

```

The size of the set **scen** defines the maximal number of scenarios we are willing to store results for. It does not have to match the number of scenarios that are actually generated in the solution process. Assume that the size of the set **scen** is n and n is smaller than the number of generated scenarios. In this case only the results for the first n scenarios will be stored. On the other hand, if the size of **scen** is larger than the number of generated scenarios, then the positions of the surplus elements of **scen** will be empty in the parameters (e.g. **s_d**).

The elements of the three-dimensional set **dict** determine which scenario-dependent values will be stored. The set contains mapping information between the symbols in the model in the first position and the symbols in which scenario solution information is stored in the third position. The type of storing is specified in the second position. The following entries are allowed:

Label	Description
level	Stores the level values of a scenario solution of a variable or equation.
marginal	Stores the marginal values of a scenario solution of a variable or equation.
randvar	Stores the realization of a random variable.
opt	Stores the probability of each scenario.
scenario	The symbol in the first position of the tuple is used as the scenario index.

Table 4 Entries in the second position of the tuples in the scenario dictionary

Attention

The first two tuples in the set **dict** are mandatory, all other elements of the set are optional. If one of the first two tuples is missing, the stochastic model cannot be solved and an error will be generated.

In the example above, we store the realization for each scenario of the random variable **d** in the parameter **s_d**, the level values of the variables **s** and **x** in the parameters **s_s** and **s_x** respectively and the actual probability of each scenario in the parameter **s_rep**.

Note

Storing and retrieving the actual probabilities of the scenarios may be particularly relevant if the probabilities have been normalized such that their sum equals 1.

Finally, the solve statement needs to be adjusted: we use the model type **EMP** and add **scenario dict** to indicate that a stochastic problem is to be solved.

4.47.11.1.3 Random Variables with Continuous Distributions Now we assume that the random variable D in the example [above](#) has a continuous distribution, say a Normal distribution with mean 45 and standard deviation 10. The structure of the problem remains unchanged, the only difference is that the set Ω , that is the set of all realizations of D , contains an infinite number of scenarios. There are various ways of modeling this. For example, a sampling procedure implemented in the solver can be used: a finite number of scenarios is generated to approximate Ω and thus the problem is converted to a problem with a finite [discrete distribution](#).

We can model a continuous distribution of the random variable in GAMS EMP by changing the annotations in the following way:

```
randvar d normal 45 10
```

Note that currently only the solver LINDO has implemented a sampling procedure for parametric distributions so that it can solve such a problem directly. If the solver DE is used, the sampling can be performed by the LINDO system behind the scenes. More details about sampling are given in the next section. All parametric distributions that can be modeled are listed in [Table 5](#).

Distribution	Parameter 1	Parameter 2	Parameter 3
Beta	shape 1	shape 2	
Cauchy	location	scale	
Chi_Square	deg. of freedom		
Exponential	lambda		
F	deg. of freedom 1	deg. of freedom 2	
Gamma	shape	scale	
Gumbel	location	scale	
Laplace	mean	scale	
Logistic	location	scale	
LogNormal	mean	std dev	
Normal	mean	std dev	
Pareto	scale	shape	
StudentT	deg. of freedom		
Triangular	low	mid	high
Uniform	low	high	
Weibull	shape	scale	
Binomial	n	p	
Geometric	p		
Hyper_Geometric	total	good	trials
Logarithmic	p-factor		
Negative_Binomial	failures	p	
Poisson	lambda		

Table 5: Parametric distributions supported by LINDO

Recall that there are two ways to specify that a specific solver should be used (that is not the default solver for the problem type): with a [command line parameter](#) (e.g. `emp=lindo`) and with an [option statement](#) (e.g. `option emp = lindo;`).

Examples with random variables that follow parametric distributions include the multistage example [below](#) (three random variables with Gamma distributions) and the production model **[PRODSP3]** in the GAMS EMP Model Library (one random variable that follows a Normal distribution and one random variable that is uniformly distributed).

4.47.11.1.4 Sampling Currently, only the solver LINDO has the ability to perform sampling for parametric distributions directly. Note that LINDO generates 6 samples by default and users need a LINDO license for sample sizes larger than 10 (smaller sample sizes are included in the demo version, but just for certain distributions). There are three ways to customize sampling: [including additional information in the EMP annotations](#), [generating a sample with the LINDO library lsadclib](#) (these two options allow to pass on the samples to other solvers with EMP SP capabilities) and setting various [options in the solver LINDO](#). We discuss each method in more detail in the next three subsections.

4.47.11.1.4.1 Customizing Sampling in the EMP Annotations The EMP framework provides two keywords to facilitate sampling: `sample` and `setSeed`. The keyword `sample` allows users to specify the size of the sample in the EMP annotations. Consider the following example:

```
randvar d normal 45 10
sample d 9
```

The second line specifies that the size of the sample of the distribution of the random variable D is 9. Note that currently the [LINDO Sampling Library](#) is used for this sampling. If the solver DE is used and a parametric distribution for the random variable is specified, the second line with the keyword `sample` is *mandatory*. Otherwise the following error message will appear:

```
*** Only random variables with sampled continuous distributions supported.
```

In addition to specifying the size of the sample, information about a mathematical variance reduction method may be added in the line that starts with the keyword `sample`. Variance reduction is a procedure used to increase the precision of the estimated values from the distribution. LINDO provides three methods for reducing the variance: Monte Carlo sampling, Latin Square sampling and Antithetic sampling. We illustrate with an example.

Consider a stochastic model with four random variables: E , F , G and H . Assume that E follows a Normal distribution with mean 23 and standard deviation 5, F follows a Normal distribution with mean 37 and standard deviation 8, G is uniformly distributed on the interval $[0, 1]$ and H is binomially distributed with $n = 100$ and $p = 0.55$. We wish that three variance reduction methods are applied: Antithetic sampling is to be used for E and F , Monte Carlo sampling for G and Latin Square sampling for H . We insert the following lines in the EMP annotations:

```
randvar e normal 23 5
randvar f normal 37 8
randvar g uniform 0 1
randvar h binomial 100 0.55
sample e f 10 method1
sample g 12 method2
sample h 8 method3
```

First, the random variables and their distributions are defined. Next, details about the sampling procedures are given. Note that the keyword `sample` can take more than one random variable if the sample size and the variance reduction method for these random variables are identical. We need to add the following lines before the solve statement to specify the content of `method1`, `method2` and `method3` (we assume that the name of the model is `nv`):

```
$onecho > lindo.opt
SVR_LS_ANTITHETIC=method1
SVR_LS_MONTECARLO=method2
SVR_LS_LATINSQUARE=method3
$offecho
nv.optfile=1;
```

If Latin Square sampling should also be used for E and F , we would simply change the EMP annotations to replace the label `method1` with the label `method3`. For more details on variance reduction methods, please consult the LINDO manual.

In addition, the EMP keyword `setSeed` may be used to further customize the sampling procedure:

```
setSeed <seed>
```

This line sets the seed (an integer number) for the random number generator of the sampling routines. If `setSeed` is used in the EMP annotations, the seed will be set once before all samples are generated. Please note that `setSeed` only works with a valid LINDO license.

4.47.11.1.4.2 Separating Sampling and Solving Users may want to sample from a distribution with the LINDO system and solve the model with another solver, say DECIS. This is possible with the sampling routines from the [LINDO Sampling Library](#) `lsadclib`. We could solve the news vendor model by first drawing a sample from a Normal distribution with mean 45 and standard deviation 10 and then using the sample in the EMP annotations. The GAMS code for sampling from a Normal distribution where the sample size is 9 follows:

```
$funcplibin mslib lsadclib

Function setSeed          / mslib.setSeed /
        sampleNormal      / mslib.sampleLSNormal /
        getSampleValues    / mslib.getSampleValues /;

Scalar k;
k = sampleNormal(45,10,9);

Set g /1*9/; parameter sv1(g);
loop(g,
    sv1(g) = getSampleValues(k);
);
display sv1;
```

The directive in the first line makes the LINDO sampling library available, `mslib` is the internal library name (see also [\\$funcLibIn](#) for more information). For further details and a list of the available probability distributions, see section [The LINDO Sampling Library](#).

In the following lines we demonstrate how the sample is used in the EMP annotations:

```
File emp / '%emp.info%' /;
put emp;
put 'randvar d discrete ' ; loop(g, put (1/card(g)) ' ' sv1(g) ' ');
$onput
stage 2 I L S d
stage 2 Row1 Row2
$offput
putclose emp;
```

Note that the third line states that the random variable D follows a discrete distribution and the probabilities and values are taken from the previously generated sample. The other lines of the annotations remain unchanged.

4.47.11.1.4.3 Sampling Options for the Solver LINDO There are some customizable sampling options in LINDO. Users could control the number of sampled scenarios by setting any of the following LINDO/SP options in the file LINDO options file `lindo.opt`:

STOC_NSAMPLE_PER_STAGE	- list of sample sizes per stage (starting at stage 2)
STOC_NSAMPLE_SPAR	- common sample size per stochastic parameter
STOC_NSAMPLE_STAGE	- common sample size per stage

For example, we could insert the following three lines before the solve statement:

```
option emp = lindo;
$echo STOC_NSAMPLE_STAGE = 100 > lindo.opt
nv.optfile = 1;
```

The first line directs GAMS to solve models of the type `emp` with the LINDO solver. The second line writes `STOC_NSAMPLE_STAGE = 100` to the file `lindo.opt`, it communicates to the solver to generate 100 samples per stage. The third line informs GAMS to use the solver option file (i.e. `lindo.opt`).

The following example shows how to use large samples and instruct LINDO to use a Benders decomposition algorithm to tackle the problem:

```
$onecho > lindo.opt
STOC_MAX_NUMSCENS = 1000000
STOC_NSAMPLE_STAGE = 40
STOC_METHOD = 1
$offecho
```

In the second line we ensure that the maximum number of scenarios is large enough. The options in the following lines state the sample size and determine the stochastic method to be used (1 means Nested Benders Decomposition). For further details on LINDO options, please consult the LINDO user manual.

4.47.11.1.5 Multistage Stochastic Programming Example The modeling principles for two-stage stochastic models can be easily extended to multistage stochastic models. At the beginning of each stage some uncertainty is resolved and recourse decisions or adjustments are made after this information has become available. At the point where decisions are made only outcomes of the current stage and previous stages are available. This logic can be pictured schematically as follows:

$$\begin{array}{c}
 \underbrace{\text{Make decision}}_{\text{Stage 1}} \rightarrow \underbrace{\text{Random Variable is realized} \rightarrow \text{Make decision}}_{\text{Stage 2}} \\
 \rightarrow \cdots \rightarrow \underbrace{\text{Random Variable is realized} \rightarrow \text{Make decision}}_{\text{Stage n}}
 \end{array} \tag{4.26}$$

Observe that random variables which are realized in stage k are fixed parameters in stage $k + 1$ and following; stage 1 random variables are in fact simply given deterministic values and will create a warning or an error dependent on the solver selected.

Consider an inventory problem. At the end of each week the decision how many hats should be bought in order to satisfy the stochastic demand in the following week must be made. The aim is to maximize the profit. We assume that the stochastic demand can be modeled using a Gamma distribution. The planning horizon is 3 weeks. *Before* the first week starts an initial purchase decision has to be made and

the goods are stored in the inventory for use in week 1. At this point only the *distribution* of the demand of the first week is known. During the first week the *actual* demand is revealed and some items that were stored in the inventory are sold. Some items may be left over; they are stored as the inventory for the second week. In addition, a purchase decision for the second week has to be made given the size of the inventory and the *distribution* of the demand in the second week. Again, the *actual* demand is revealed in the course of the second week. The same holds for the third week.

We will model the problem with 4 stages, where the first stage corresponds to the preparation time before the first week, the second stage corresponds to decisions made in the first week, the third stage corresponds to decisions made in the second week and the fourth stage corresponds to decisions made in the third week. Let t denote the stages. Note that while the stages range from $t = 1$ to $t = 4$, demand variables are realized only at $t = 2$ to $t = 4$. Let y_t be the amount bought and i_t the amount stored at the end of each stage and let D_t denote the demand in each week and s_t the amount sold each week. Note that we denote the demand with a capital D since it is a random variable. Let $\alpha = 10$ be the cost per hat bought, $\beta = 20$ the revenue per hat sold and $\delta = 4$ the storage cost per unit. Further, in the storage facility a maximum of $\kappa = 5000$ hats can be stored.

Mathematically, this problem can be expressed as follows:

$$\begin{aligned}
 \text{Max}_{s_t, y_t, i_t} \quad & z = -\alpha y_1 - \gamma i_1 + \mathbb{E}[\text{Max} \quad \beta s_2(D_2) - \alpha y_2(D_2) - \delta i_2(D_2) + \cdots + \\
 & \mathbb{E}[\text{Max} \quad \beta s_4(D_4) - \alpha y_4(D_4) - \delta i_4(D_4)] \dots] \\
 \text{s.t.} \quad & i_1 = y_1 \\
 & i_{t-1} + y_t = s_t + i_t \\
 & s_t \leq i_{t-1} \\
 & s_t \leq D_t \\
 & i_t \leq \kappa \\
 & y_1, i_1, s_t, y_t, i_t \geq 0,
 \end{aligned} \tag{35}$$

where $t = 2, \dots, 4$ and D_t follows a Gamma distribution. Note that s_t , y_t and i_t depend on the realization of D_t .

As discussed [above](#), the solvers use a sampling procedure to approximate a problem with a continuous random variable by a problem with a discrete distribution. [Figure 1](#) illustrates the stages assuming a sample size of 6 (per stage). Note that this results in a total of $6^3 = 216$ scenarios.

The problem can be modeled with GAMS EMP as follows:

```

* Core Model
Set t          "stages" / 1*4 /;
Set st(t)      "stages where sales occur" / 2*4 /;

Positive Variables
    y(t)        "units to be bought in time period t"
    i(t)        "ending inventory in period t"
    s(t)        "units sold in time period t" ;

Free Variable
    profit ;

Scalars
    kappa       "capacity of storage building" / 5000 /
    alpha       "cost per unit bought" / 10 /
    beta        "revenue per unit sold" / 20 /
    delta       "cost per unit stored at the end of time period" / 4 /;

Parameters

Set scen          "scenarios" / s1*s216 /;
Parameters
    s_d(scen,st) "demand realization by scenario"
    s_y(scen,t)  "units bought by scenario"
    s_s(scen,t)  "units sold by scenario"
    s_i(scen,t)  "units stored by scenario" ;

Set dict /
    scen .scenario.''
    d    .randvar .s_d
    s    .level   .s_s
    y    .level   .s_y
    i    .level   .s_i /;

option emp=lindo;
solve inventory max profit using emp scenario dict;
display s_d, s_s, s_y, s_i;

```

Observe that in the [core problem](#) the values of the demand $d(t)$ are replaced by the expected values of the random variable D_t which follows a Gamma distribution. Note that as expected, in stage 1 we have only the variables y and i , but no variables s and d . Recall that currently only the solver LINDO can solve models with parametric distributions, see sections [Random Variables with Continuous Distributions](#) and [Sampling](#) for more information.

4.47.11.1.6 EMP Syntax for Stochastic Programs with Recourse The general syntax of the [EMP annotations](#) used to specify stochastic problems with recourse is as follows:

```

[randvar rv discrete prob val {prob val}]
[randvar rv distr par {par}]
[jrandvar rv rv {rv} prob val val {val} {prob val val {val}}]
[setSeed number]
[sample rv1 [rv2 ... rvn] sampleSize [varRedMethod]]
stage stageNo rv | equ | var {rv | equ | var}
{stage stageNo rv | equ | var {rv | equ | var}}

```

The first three lines present three ways to specify random variables: a single random variable with a discrete distribution, a single random variable with a parametric distribution and joint random variables with discrete distributions. Note that **randvar**, **jrandvar** and **discrete** are [EMP keywords](#). The distribution of single discrete random variables is defined by pairs of the probability **prob** of an outcome and the corresponding realization **val**, see example [above](#). The distribution of parametric random variables is defined by the name of the distribution **distr** and the respective parameter(s) **par**. An overview of all supported parametric distributions can be found in [Table 5](#). All possible values for **distr** and the related parameters **par** are listed there. The keyword **jrandvar** is used to define discrete random variables that are *jointly* distributed. At least two random variables must be named. For an example, see the news vendor model [\[NBDISCJOINT\]](#).

Note

At least one random variable must be defined and all three ways to define random variables may appear in the EMP annotations. See the scheduling model [\[AIRLIFT\]](#) for an example with both, a discrete random variable and a continuous random variable.

The keywords `setSeed` and `sample` are optional. The seed for the random number generator may be set with `setSeed`. The random number generator is used for the sampling routines that are called with the keyword `sample`. If `setSeed` is used, the seed will be set once before all samples will be generated. The keyword `sample` is followed by the name of the respective random variable, the sample size (a number) and - optionally - a variance reduction method. Note that the random variable must have been previously declared to follow a parametric distribution. Note further, that the sample size of more than one random variable may be customized simultaneously. Observe that the default sample size is 6. For details on available variance reduction methods, see section [Customizing Sampling in the EMP Annotations](#).

Note

- A valid LINDO license is required to use the keywords `setSeed` and `sample`. The keyword `sample` may be used with the demo version of the LINDO license that is included with all GAMS distributions, but it is limited to the Normal and Binomial distributions with a maximum sample size of 10.
- If a parametric distribution is used with any solver but LINDO, the keyword `sample` is mandatory, see [above](#) for details.

With the keyword `stage` random variables, variables and equations are assigned to their respective stages, where `StageNo` defines the stage number. Note that the default stage for all random variables, equations and variables is 1, except for the objective equation and variable. The default for those is the highest stage in the problem.

4.47.11.2 Risk Measures with EMP

The literature on stochastic programming usually assumes that the expected value of the objective is optimized. The EMP tool follows this trend and implicitly optimizes the expected value. However, there are other risk measures that could be taken into consideration and that are frequently used in practice, particularly in finance. For example, a fund manager might be more interested in the expected value of the 10% worst cases of the projected wins than in the expected value of the overall distribution. The expected value of a partition of the distribution at one tail is called *Conditional Value at Risk*. The EMP framework provides special keywords to facilitate optimizing this risk measure. On a more abstract level, risk measures can be understood as mechanisms to evaluate the effects of uncertainty in the underlying system on the outcomes of interest. They can be used to modify the distribution of outcomes.

Using the example of an investor who wishes to balance expected rewards and the risk of loss when she decides how to allocate assets in a portfolio, we explore how stochastic optimization problems involving risk measures can be modeled with EMP. Note that this example is adapted from the stochastic portfolio model [\[PORTFOLIO\]](#). For simplicity of exposition, we only describe two-stage models here. In the examples that follow, the period $(0, T)$ is the period between investing in a portfolio of assets and return from this portfolio.

We first present the example problem and introduce a new EMP keyword to model the [expected value explicitly](#). Then we introduce and discuss [Value at Risk \(VaR\)](#) and [Conditional Value at Risk \(CVaR\)](#). At the end of this section, we give a [summary of the EMP annotations](#) that are specific to risk measures.

Note

The stochastic extension of EMP facilitates the optimization of a single risk measure or a combination of risk measures (for example, the weighted sum of Expected Value and CVaR). In addition, the modeler can choose to trade off risk measures.

4.47.11.2.1 Expected Value Revisited Suppose an investor has the opportunity to invest a certain amount in three assets. She is given the probability distribution in [Table 6](#) that links each asset with a possible return at time T . The question arises how she should allocate her funds between the three assets at time 0 in order to maximize her *expected* return at time T .

Scenario	Probability	ATT	GMC	USX
s1	1/12	1.300	1.225	1.149
s2	1/12	1.103	1.290	1.260
s3	1/12	1.216	1.216	1.419
s4	1/12	0.954	0.728	0.922
s5	1/12	0.929	1.144	1.169
s6	1/12	1.056	1.107	0.965
s7	1/12	1.038	1.321	1.133
s8	1/12	1.089	1.305	1.732
s9	1/12	1.090	1.195	1.021
s10	1/12	1.083	1.390	1.131
s11	1/12	1.035	0.928	1.006
s12	1/12	1.176	1.715	1.908

Table 6: Return by scenario

Mathematically, the problem can be expressed as follows:

$$\begin{aligned}
 &\text{Max} \quad \mathbb{E}[R] \\
 &\text{s.t} \quad R = \sum_j w_j v_j \\
 &\quad \sum_j w_j = 1 \\
 &\quad w_j \geq 0,
 \end{aligned} \tag{36}$$

where the variable R denotes the return and is a function of the random variable v , $\mathbb{E}[R]$ is the expected return, w_j is the weight associated with each asset j , and v_j is the return of each asset j . The weights can also be interpreted as proportions of the amount to be invested, their sum must equal 1. Note that w_j is the decision variable in this problem. Note further, that v_j is a random variable that depends on which scenario is realized.

We present two different ways to model this problem in GAMS EMP: in the first version the expected value of the return is modeled *implicitly* and in the second version it is modeled *explicitly*. Both models have two stages, in the first stage the weights are chosen without knowing which scenario will be realized, in the second stage the 12 scenarios are taken into account. We start with the part of the code where the data is given. It is named `data.gms` and it will be included in all models in this section.

```

Sets    j          "assets"      / att, gmc, usx /
        s          "scenarios"   / s1*s12 / ;

```

Table vs(s,j) "scenario returns from assets"

	att	gmc	usx
s1	1.300	1.225	1.149
s2	1.103	1.290	1.260
s3	1.216	1.216	1.419
s4	0.954	0.728	0.922
s5	0.929	1.144	1.169
s6	1.056	1.107	0.965
s7	1.038	1.321	1.133
s8	1.089	1.305	1.732
s9	1.090	1.195	1.021
s10	1.083	1.390	1.131
s11	1.035	0.928	1.006

```
s12  1.176   1.715   1.908 ;

    s_v(s,j)   "return from assets by scenario"  
    s_r(s)     "return from portfolio by scenario" ;
```

```
Set    dict / s .scenario. ''
```

```
        v .randvar .s_v
```

```
        r .level .s_r /;
```

```
solve portfolio using emp max r scenario dict;
```

```
display s_v, s_r;
```

As usual, the core model is defined first and the specifications relating to the stochastic structure of the model are written to the file `emp.info`. Note that the statement `emp.nd=4` ensures that 4 decimal places are used for the values of the parameter `vs`. In the first line of the [EMP annotations](#), the variables `v` and `r` and the equation `defr` are assigned to the second stage. Note that the other variables and equations (in this case, the variable `w` and the equation `budget`) are automatically assigned to the first stage. In the second line of the annotations, the [EMP keyword](#) `jrandvar` is used to declare that `v('att')`, `v('gmc')`

and `v('usx')` are *joint* random variables, i.e. they are jointly distributed (thus we have 12 scenarios and not $12 \times 12 \times 12 = 1728$ scenarios). The respective probabilities and values are specified with a [loop statement](#). Observe that the syntax of the solve statement suggests that the return `r` is maximized. However, `r` is in fact a random variable, since it is a function of random variables, so actually the *expected* return is maximized.

In the second model we introduce a new variable for the expected return, `evr`. This new variable is linked to the [EMP keyword](#) `ExpectedValue` in the annotations, thus it is made explicit that the expected value of the return is optimized.

```
* Core Model
$include data.gms
Variables
    r          "value of portfolio under each scenario"
    w(j)       "portfolio selection"
    evr        "expected value of r"
    obj        "objective variable" ;
Positive Variables
    w ;

Equations
    defr       "return of portfolio"
    budget     "budget constraint"
    defobj     "objective equation" ;

defr..        r =e= sum(j, v(j)*w(j));
budget..      sum(j, w(j)) =e= 1;
defobj..      obj =e= evr;

Model portfolio / all /;

* EMP Annotations

emp.nd=4;
put emp '* problem %gams.i%'
    / 'ExpectedValue r evr'
    / 'stage 1 obj defobj evr'
    / 'stage 2 v defr r'
    / "jrandvar v('att') v('gmc') v('usx')";
loop(s,
    put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
    s_v(s,j) "return from assets by scenario"
    s_r(s)   "return from portfolio by scenario" ;

Set dict / s .scenario.'
    v .randvar .s_v
    r .level .s_r /;

solve portfolio using emp max obj scenario dict;
```

In the EMP annotations, the [EMP keyword](#) `ExpectedValue` is followed by the variable `r` and the variable `evr`. In this way the variable `evr` is declared to be the expected value of the (random) variable `r`. Note that the new variables `evr` and `obj` belong to stage 1 and the variable `evr` is maximized (via `obj`). The

remainder of the annotations and the code referring to the output-handling information in the dictionary are the same like in the [first model](#). Both models have the same solution. We prefer the second model since the syntax is more explicit and clearer.

Observe that the keyword `ExpectedValue` is particularly useful if users wish to model an objective that is the weighted sum of several risk measures, thus trading-off different risk measures. An [example](#) with the weighted sum of the expected value and Value at Risk as objective and an [example](#) with the weighted sum of the expected value and Conditional Value at Risk as objective are given below.

4.47.11.2.2 Value at Risk (VaR) The Value at Risk (VaR) is the value of the distribution at a given cut-off point; for example, the value of the standard Normal distribution at the point x such that 95% of the distribution is to the left. In this subsection we introduce the notion of VaR in more detail by developing a [mathematical formulation](#), demonstrating how VaR can be modeled with GAMS EMP using a [simple example](#) and showing how to optimize the [weighted sum of the expected value and VaR](#).

4.47.11.2.2.1 VaR: Mathematical Formulation Suppose $G(x, \xi)$ is a real valued function of the decision vector x and a random data vector ξ and that it denotes the *loss* function of a portfolio of assets. We aim to restrict potential losses and so we choose a portfolio composition such that the loss only exceeds a certain threshold γ ($\gamma \in \mathbb{R}$) with a probability smaller or equal to α , $\alpha \in (0, 1)$, where α is small. This condition can be modeled as a [chance constraint](#) and has the following form:

$$P(G(x, \xi) > \gamma) \leq \alpha \quad (37)$$

It is easy to see that this can be written in the following way:

$$P(G(x, \xi) - \gamma \leq 0) \geq 1 - \alpha. \quad (38)$$

Consider the random variable $Z_x := G(x, \xi) - \gamma$. For a given value of x , let $F_Z(z) := P(Z \leq z)$ be the cumulative distribution function of Z . Now, the point x satisfies the constraint (37) if and only if $F_Z(0) \geq 1 - \alpha$. This is equivalent to saying that x satisfies the constraint (39) if and only if $F_Z^{-1}(1 - \alpha) \leq 0$.

The (left-side) quantile $F_Z^{-1}(\theta)$ is called *Value at Risk*. It is denoted by $VaR_\theta(Z)$, i.e.

$$VaR_\theta(Z) = \inf\{t : F_Z(t) \geq \theta\}. \quad (39)$$

Hence constraint (38) can be written in the following equivalent form:

$$VaR_{1-\alpha}(G(x, \xi)) \leq \gamma. \quad (40)$$

Value at Risk as introduced in equation (39) refers to a percentile on the *left* tail of a distribution. From now on it will be denoted by $\underline{VaR}_\theta(Z)$. When considering the Value at Risk at the *right* tail of the distribution, θ typically equals 0.9 or 0.95, it is denoted by $\overline{VaR}_\theta(Z)$.

[Figure 2](#) illustrates $\underline{VaR}_{0.05}(Z)$, where Z is normally distributed with mean $\mu = 0.645$ and standard deviation $\sigma = 1$.

The EMP framework provides the [EMP keywords](#) `varlo` and `varup` as a convenient alternative to chance constraints to model Value at Risk.

Figure 4.2 VaR and CVaR

4.47.11.2.2.2 VaR with EMP: A Simple Example We continue to illustrate with the stochastic portfolio model that we have already used [above](#). Consider that the investor might be interested in a strategy that maximizes the threshold at a certain cutoff, say at 10% on the left tail of the return curve. Mathematically, the problem can be expressed as follows:

$$\begin{aligned}
 &\text{Max} \quad \underline{VaR}_\theta[R] \\
 &\text{s.t} \quad R = \sum_j w_j v_j \\
 &\quad \quad \sum_j w_j = 1 \\
 &\quad \quad w_j \geq 0,
 \end{aligned} \tag{41}$$

where $\underline{VaR}_\theta$ is the Value at Risk at the lower θ th percentile.

In the [EMP annotations](#) of the corresponding GAMS model we introduce a new variable for VaR (`varr`), a scalar to specify the percentile we are interested in (`theta`) and the [EMP keyword](#) `varlo`:

```

* Core Model
$include data.gms
Variables
    r          "value of portfolio under each scenario"
    w(j)       "portfolio selection"
    varr       "value at risk of r"
    obj        "objective variable" ;
Positive Variables
    w ;

```

```

Scalar
    theta    "relative volume" / 0.1 /;

Equations
    defr      "return of portfolio"
    budget    "budget constraint"
    defobj    "objective equation" ;

defr..      r =e= sum(j, v(j)*w(j));
budget..    sum(j, w(j)) =e= 1;
defobj..    obj =e= varr;

Model portfolio / all /;

* EMP Annotations
File emp / '%emp.info%' /
put emp '* problem %gams.i%'
    / 'varlo r varr ' theta
    / 'stage 1 obj defobj varr'
    / 'stage 2 r defr v'
    / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
    put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
    s_v(s,j) "return from assets by scenario"
    s_r(s)   "return from portfolio by scenario" ;

Set    dict / s   .scenario.''
        v   .randvar .s_v
        r   .level  .s_r /;

solve portfolio using emp max obj scenario dict;

```

The first line in the [EMP annotations](#) begins with the EMP keyword `varlo`. This line specifies that the variable `varr` is the Value at Risk relating to the random variable `r` and the scalar `theta` is the percentile (in range 0 to 1) we consider. The other lines in the annotations are similar to the [second model above](#). Note that the objective equals the Value at Risk at the left tail, denoted by $\underline{VaR}$.

Observe that the EMP keyword `varlo` specifies VaR at the *left* tail of the probability distribution. For the *right* tail of the distribution, the EMP keyword to be used is `varup`.

Note

- The keyword `var` is identical to `varup` which refers to the right tail of the distribution.
- Currently only the solver DE supports the keywords for VaR.

Note further, that it is only appropriate to maximize $\underline{VaR}_\alpha$ and minimize $\overline{VaR}_\alpha$.

The implementation of the keywords `varlo` and `varup` is based on a mixed integer program similar to that described in section [Example with a Single Chance Constraint](#). Observe that these implementations are likely to be hard and/or time consuming to solve. There is an option that allows users to customize the big M value (default is 1000) in the same manner that we outline [below](#):

```
$onecho > de.opt
VaRBigM = 500
$offecho
portfolio.optfile=1;
```

Observe that the EMP framework offers an alternative, shorter way to model VaR. There is no additional variable for VaR, hence in the EMP annotations, the EMP keyword `varlo` is only followed by `theta` and the objective variable in the solve statement is `r`. As `varlo` is specified in the annotations, the risk measure is applied to the objective variable implicitly. The modified EMP annotations and the new solve statement follow.

```
File emp / '%emp.info%' /;
put emp '* problem %gams.i%'
      / 'varlo ' theta
      / 'stage 2 r defr v'
      / "jrandvar v('att') v('gmc') v('usx')"
loop(s, put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;
...
solve portfolio using emp max r scenario dict;
```

Note that this alternative notation is shorter, but it is also opaque, therefore we recommend the first way.

4.47.11.2.2.3 Combining VaR and Expected Value In a variation of the example [above](#), consider an investor who aims to take into account both, the expected return and the Value at Risk of the return at a certain threshold θ . She combines the two risk measures and uses a scalar (λ) as a weight. A mathematical formulation of the problem reads as follows:

$$\begin{aligned}
 \text{Max} \quad & \lambda \mathbb{E}[R] + (1 - \lambda) \underline{VaR}_\theta[R] \\
 \text{s.t} \quad & R = \sum_j w_j v_j \\
 & \sum_j w_j = 1 \\
 & w_j \geq 0,
 \end{aligned} \tag{42}$$

where $\mathbb{E}[R]$ is the expected value of the return and $\underline{VaR}_\theta$ is the Value at Risk at the θ th percentile.

This problem can be modeled in GAMS EMP as follows:

```
* Core Model
$include data.gms
Variables
    r          "value of portfolio under each scenario"
    w(j)       "portfolio selection"
    varr       "value at risk of r"
    evr        "expected value of r"
    obj        "objective variable" ;
Positive Variables
    w ;

Scalars
    theta      "relative volume" / 0.1 /
    lambda     "weight EV versus VaR" / 0.2 /;

Equations
```

```

    defr      "return of portfolio"
    budget    "budget constraint"
    defobj    "convex combination of both risk measures" ;

defr..      r =e= sum(j, v(j)*w(j));
budget..    sum(j, w(j)) =e= 1;
defobj..    obj =e= lambda*evr + (1-lambda)*varr;

Model portfolio_ext / all /;

* EMP Annotations
File emp / '%emp.info%' /
put emp '* problem %gams.i%'
      / 'ExpectedValue r evr'
      / 'varlo r varr ' theta
      / 'stage 2 r defr v'
      / 'stage 1 defobj obj'
      / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
  put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
  s_v(s,j) "return from assets by scenario /s1.att 1/"
  s_r(s)   "return from portfolio by scenario" ;

Set  dict / s  .scenario.''
      v  .randvar .s_v
      r  .level   .s_r /;

solve portfolio_ext using EMP max obj scenario dict;

```

Note that we introduced a variable for the expected value of the return like in the [example above](#) where we modeled the expected return explicitly. Note further, that we added the parameter `lambda` and we defined the variable `obj` to be the weighted sum of the expected value of the return `evr` and the lower VaR `varr`. Observe that in the EMP annotations both keywords `ExpectedValue` and `varlo` are used. The other parts of the model remain unchanged.

4.47.11.2.3 Conditional Value at Risk (CVaR) The Conditional Value at Risk (CVaR) is the expected value of the left or right tail of the distribution; for example, the expected value of the left 5% of the standard Normal distribution. Note that CVaR is also called *expected shortfall*. In this subsection we introduce and discuss CVaR in more detail by presenting a [mathematical formulation](#), demonstrating how CVaR can be modeled with GAMS EMP using a [simple example](#) and showing how to optimize the [weighted sum of the expected value and CVaR](#).

4.47.11.2.3.1 CVaR: Mathematical Formulation $\underline{CVaR}_\alpha$ is the expected average return (in a given time period) given that we are in the $(\alpha \times 100)\%$ *left tail* of the return distribution, where $\alpha \in (0, 1)$. In other words, $\underline{CVaR}_\alpha$ is a mean of the left tail. For example, if we are interested in the 5% worst cases, i.e. $\alpha = 0.05$, $\underline{CVaR}_\alpha$ is the conditional expectation of the return, given the return is no greater than VaR.

Let ξ be a random variable with probability density function $p(\xi)$, let $G(\xi)$ be a function of the random variable ξ denoting the *return* of a portfolio of assets and let $\alpha \in (0, 1)$ be a probability. Then the conditional value at risk of $G(\xi)$ is defined as

$$\underline{CVaR}_\alpha(G(\xi)) = \frac{1}{\alpha} \int_{-\infty}^{\text{VaR}_\alpha} G(\xi) \cdot p(\xi) d\xi, \quad (43)$$

where VaR_α is the value at risk.

4.47.11.2.3.2 CVaR with EMP: A Simple Example In the stochastic portfolio example that we have used throughout this section, the investor might be interested to make sure that in the worst cases she loses as little as possible. Thus she could consider only the worst 10% of possible cases and allocate her funds such that the expected mean return in these cases is maximized. Mathematically, the problem can be expressed as follows:

$$\begin{aligned} \text{Max} \quad & \underline{CVaR}_\theta[R] \\ \text{s.t} \quad & R = \sum_j w_j v_j \\ & \sum_j w_j = 1 \\ & w_j \geq 0, \end{aligned} \tag{44}$$

where $\underline{CVaR}_\theta$ is the CVaR at the confidence level θ at the *left* tail of the distribution.

Like in the case of Value at Risk [above](#), we introduce a new variable for CVaR (`cvarr`), a scalar to specify the percentile we are interested in (`theta`) and the EMP keyword `cvarlo` in the [EMP annotations](#):

```
* Core Model
$include data.gms
Variables
    r          "value of portfolio under each scenario"
    w(j)       "portfolio selection"
    cvarr      "conditional value at risk of r"
    obj        "objective variable" ;
Positive Variables
    w ;

Scalar
    theta      "relative volume" / 0.1 /;

Equations
    defr       "return of portfolio"
    budget     "budget constraint"
    defobj     "objective equation" ;

defr..        r =e= sum(j, v(j)*w(j));
budget..      sum(j, w(j)) =e= 1;
defobj..      obj =e= cvarr;

Model portfolio / all /;

* EMP Annotations
File emp / '%emp.info%' /
put emp '* problem %gams.i%'
    / 'cvarlo r cvarr' theta
    / 'stage 1 obj defobj cvarr'
    / 'stage 2 r defr v'
    / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
    put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
```

```

s_v(s,j) "return from assets by scenario"
s_r(s)   "return from portfolio by scenario" ;

Set dict / s .scenario.''
        v .randvar .s_v
        r .level   .s_r /;

solve portfolio using emp max obj scenario dict;

```

In the EMP annotations, the first line starts with the EMP keyword `cvarlo`. This line specifies that the variable `cvarr` is the left-tail CVaR relating to the random variable `r` and the scalar `theta` is the fraction (in range 0 to 1) we consider. Like in the previous section, the objective variable, the objective equation and the variable in the objective equation belong to the first stage while the equation that handles the random data and all its variables belong to the second stage. Observe that the objective equals the Conditional Value at Risk.

Note that the keyword `cvarlo` specifies CVaR at the *left* tail of the probability distribution. For the *right* tail of the distribution the keyword to be used is `cvarup`.

Note

- The EMP keyword `cvar` is identical to the keyword `cvarup`.
- Currently only the solver DE supports the keywords for CVaR.

The conditional value at risk denoting the mean of the *right* tail of the distribution can be denoted by $\overline{CVaR}$ and is defined as:

$$\overline{CVaR}_\alpha(G(\xi)) = \frac{1}{1-\alpha} \int_{VaR_\alpha}^{\infty} G(\xi) \cdot p(\xi) d\xi. \quad (45)$$

Observe that it is only appropriate to maximize $\underline{CVaR}_\alpha$ and minimize $\overline{CVaR}_\alpha$. Furthermore, $\underline{CVaR}_\alpha$ is a concave function and so should only be constrained using e.g.

$$\underline{CVaR}_\alpha \geq \gamma$$

and $\overline{CVaR}_\alpha$ is convex, so should only appear in constraints like

$$\overline{CVaR}_\alpha \leq \gamma.$$

The EMP framework offers an alternative way to model CVaR. In this alternative formulation, there is no additional variable for CVaR, hence in the EMP annotations, the EMP keyword `cvarlo` is only followed by `theta` and the objective variable in the solve statement is `r`. As `cvarlo` is specified in the annotations, the risk measure is applied to the objective variable implicitly. The modified EMP annotations and the new solve statement follow.

```

File emp / '%emp.info%' /
put emp '* problem %gams.i%'
      / 'cvarlo ' theta
      / 'stage 2 r defr v'
      / "jrandvar v('att') v('gmc') v('usx')"
loop(s, put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;
...
solve portfolio using emp max r scenario dict;

```

Note that this alternative notation is shorter, but it is considerably less clear, therefore we recommend the explicit notation of the first model.

4.47.11.2.3.3 Combining CVaR and Expected Value In a final variation on the portfolio example, we consider an investor who aims to take into account both, the expected return and the Conditional Value at Risk of the return at a certain threshold θ . She combines the two risk measures and uses a scalar (λ) to weigh the two summands. A mathematical formulation of the problem reads as follows:

$$\begin{aligned} \text{Max} \quad & \lambda \mathbb{E}[R] + (1 - \lambda) \underline{CVaR}_\theta[R] \\ \text{s.t} \quad & R = \sum_j w_j v_j \\ & \sum_j w_j = 1 \\ & w_j \geq 0, \end{aligned} \tag{46}$$

where $\mathbb{E}[R]$ is the expected value of the return and $\underline{CVaR}_\theta$ is the CVaR at the confidence level θ .

This problem can be modeled with GAMS EMP as follows:

```
* Core Model
$include data.gms
Variables
    r          "value of portfolio under each scenario"
    w(j)       "portfolio selection"
    cvarr      "conditional value at risk of r"
    evr        "expected value of r"
    obj        "objective variable" ;
Positive Variables
    w ;

Scalars
    theta      "relative volume" / 0.1 /
    lambda      "weight EV versus CVaR" / 0.2 /;

Equations
    defr        "return of portfolio"
    budget      "budget constraint"
    defobj      "convex combination of both risk measures" ;

defr..         r =e= sum(j, v(j)*w(j));
budget..       sum(j, w(j)) =e= 1;
defobj..       obj =e= lambda*evr + (1-lambda)*cvarr;

Model portfolio_ext / all /;

* EMP Annotations
File emp / '%emp.info%' /
put emp '* problem %gams.i%'
    / 'ExpectedValue r evr'
    / 'cvarlo r cvarr ' theta
    / 'stage 2 r defr v'
    / 'stage 1 defobj obj'
    / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
    put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
    s_v(s,j) "return from assets by scenario"
    s_r(s)   "return from portfolio by scenario" ;
```

```

Set    dict / s .scenario.'
        v .randvar .s_v
        r .level   .s_r /;

solve portfolio_ext using emp max obj scenario dict;

```

Note that apart from the EMP keyword `varlo` being replaced by `cvarlo`, the code is identical to the code [above](#), where we maximized the weighted sum of the expected value and VaR. Observe that by decreasing the value of λ from 1 to 0 we can explore the results of an increasingly risk averse behavior.

4.47.11.2.4 EMP Syntax for Risk Measures The EMP annotations where risk measures are used have the same general syntax like [stochastic models with recourse](#). In addition, the following keywords may be used:

```

ExpectedValue rv var
varlo [rv var] scalar
varup [rv var] scalar
cvarlo [rv var] scalar
cvarup [rv var] scalar

```

The EMP keyword `Expected Value` is used to state that the variable `var` is the expected value of the random variable `rv`. Note that the random variable `rv` must be defined to be a random variable in the EMP annotations.

The EMP keywords `varlo`, `varup`, `cvarlo` and `cvarup` refer to VaR at the left tail of the distribution ($\underline{VaR}_\alpha$), VaR at the right tail of the distribution ($\overline{VaR}_\alpha$), CVaR at the left tail of the distribution ($\underline{CVaR}_\alpha$) and CVaR at the right tail of the distribution ($\overline{CVaR}_\alpha$) respectively.

Note

The EMP keyword `var` is a synonym to `varup` and `cvar` is a synonym to `cvarup`.

The specifications that follow all four keywords have a long and a short version. In the long version, the random variable `rv` and the variable that is assigned to be the respective risk measure (VaR or CVaR) are named explicitly. The scalar is a number in the interval $(0, 1)$, it defines the percentile in VaR and confidence level in CVaR. In the short version, only the scalar is specified. In this case the risk measure will be applied to the objective variable implicitly.

Note

These five keywords are only supported by the solver DE.

4.47.11.3 Chance Constraints with EMP

In stochastic programs with chance constraints the goal is to make an optimal decision prior to the realization of random data while allowing the constraints (or some of them) to be violated with a certain probability. Note that chance constraints are also called *probabilistic constraints*.

This section is organized as follows. After introducing a [mathematical formulation](#) of chance constraints, we show how such problems can be modeled with GAMS EMP using a simple example with only [one chance constraint](#). Then we extend the model to include [multiple chance constraints](#). We discuss the two ways to model problems with multiple chance constraints: using *joint chance constraints* and using *individual chance constraints*. [Joint chance constraints](#) require that all constraints are satisfied simultaneously with a given probability. [Individual chance constraints](#) require each constraint to be satisfied with a given probability independently of other constraints. Further, the EMP framework offers the option to penalize the violation of chance constraints. This is the topic of subsection [Penalizing Violations of Chance Constraints](#). We conclude this section with an overview of the EMP annotations that are [specific to chance constraints](#).

4.47.11.3.1 Chance Constraints: Mathematical Formulation Mathematically, a stochastic linear program with chance constraints can be expressed as follows:

$$\begin{aligned} \text{Min}_x \quad & c^T x \\ \text{s.t.} \quad & P(Ax \leq b) \geq p \\ & x \geq 0, \end{aligned} \tag{47}$$

where $x \in \mathbb{R}^n$ is the decision variable and c^T denotes the coefficients of the objective function, $A \in \mathbb{R}^{m \times n}$ is a random matrix and represents the coefficients and $b \in \mathbb{R}^m$ is a random vector and denotes the right-hand side of the constraints. The distinctive feature of stochastic programs with chance constraints is that the constraints (or some of them) may be violated with probability $\epsilon = 1 - p$, where $0 < p \leq 1$. Note that ϵ is sometimes called the *risk tolerance*.

One way to solve a stochastic problem with chance constraints is to convert it to a mixed-integer problem (MIP) first and then solve the MIP equivalent. The idea is to introduce a set of scenarios S and a vector with binary variables, say $y_k \in \mathbb{R}^m$, for each scenario $k \in S$. The binary variables take value 1 if the corresponding constraint is satisfied in a scenario and 0 otherwise. A scenario-based formulation of the chance-constrained stochastic linear program above can be written as:

$$\begin{aligned} \text{Min}_x \quad & c^T x \\ \text{s.t.} \quad & A^k x \leq b^k + M^k(1 - y_k) \\ & \sum_{k \in S} y_k \geq p \times |S| \\ & x \geq 0, \quad y \in (0, 1)^{|S|}, \end{aligned} \tag{48}$$

where $M^k \in \mathbb{R}^m$ is a chosen big-M vector. The entries of the vector M^k should be chosen such that it does not cut off any feasible solution if $y_k = 0$.

4.47.11.3.2 Example with a Single Chance Constraint We start with the simplest case, where the random matrix A consists of just one random vector a , resulting in a problem with a single chance constraint. The following example is adapted from model [SIMPLECHANCE].

$$\begin{aligned} \text{Min} \quad & x_1 + x_2 \\ \text{s.t.} \quad & P(\omega x_1 + x_2 \geq 7) \geq 0.75, \quad \omega \in \Omega = \{1, 2, 3, 4\} \\ & x_1, x_2 \geq 0. \end{aligned} \tag{49}$$

Here the random parameter ω has four possible realizations. Thus we have four scenarios and we assume that each scenario is equally likely to be realized, i.e. $\pi^k = \frac{1}{4}$, where π^k denotes the probability that scenario k is realized. Note that in this example b is fixed at 7. As $p = 0.75$ and each scenario is equally likely to be realized, we need to choose x_1 and x_2 such that the inequality is satisfied in at least 3 scenarios. For clarity, we spell out the inequalities for the scenarios:

$$\begin{aligned} k = 1 : \quad & \omega_1 = 1 \quad \omega_1 x_1 + x_2 \geq 7 \\ k = 2 : \quad & \omega_2 = 2 \quad \omega_2 x_1 + x_2 \geq 7 \\ k = 3 : \quad & \omega_3 = 3 \quad \omega_3 x_1 + x_2 \geq 7 \\ k = 4 : \quad & \omega_4 = 4 \quad \omega_4 x_1 + x_2 \geq 7. \end{aligned} \tag{50}$$

The MIP equivalent of problem (49) is given below:

$$\begin{aligned}
 &\text{Min} && x_1 + x_2 \\
 &\text{s.t.} && 1x_1 + x_2 \geq 7 - M(1 - y_1) \\
 &&& 2x_1 + x_2 \geq 7 - M(1 - y_2) \\
 &&& 3x_1 + x_2 \geq 7 - M(1 - y_3) \\
 &&& 4x_1 + x_2 \geq 7 - M(1 - y_4) \\
 &&& cc_1 = 1 - \sum_k \pi^k y_k, \quad k = 1, \dots, 4, \pi^k = \frac{1}{4} \\
 &&& x_1, x_2 \geq 0 \\
 &&& 0 \leq cc_1 \leq (1 - 0.75) \\
 &&& y_k \in (0, 1).
 \end{aligned} \tag{51}$$

Observe that the first four constraints cover the four possible scenarios with ω taking the values 1, 2, 3 and 4 respectively. On the right-hand side we introduce a big-M factor and y_k , a binary indicator variable. y_k takes the value 1 if the constraint is satisfied and zero otherwise. The new variable cc_1 represents the probability that the constraint is violated. If cc_1 equals zero, the sum will equal 1, indicating that the constraint is satisfied in all four scenarios. If $cc_1 = 0.25$, the constraint will be unsatisfied in one scenario out of four (for this scenario $y_k = 0$).

The problem can be modeled in GAMS EMP as follows:

```

* Core Model
Positive Variables x1, x2;
Variables          z;

Scalar om / 1 /;

Equations obj, e1;

obj..    z =e= x1 + x2;
e1..     om*x1 + x2 =g= 7;

Model sc / all /;

* EMP Annotations
File emp / '%emp.info%' /;
put emp;
$onput
randvar om discrete 0.25 1 0.25 2 0.25 3 0.25 4
chance e1 0.75
$offput
putclose emp;

* Dictionary
Set scen "scenarios" / s1*s4 /;
Parameter s_om(scen)
          x1_l(scen)
          x2_l(scen)
          e1_l(scen);

Set dict / scen .scenario.'
          om .randvar .s_om
          x1 .level .x1_l
          x2 .level .x2_l

```

```

e1 .level .e1_l/;

solve sc min z use EMP scenario dict;
display s_om, x1_l, x2_l, e1_l;

```

Like other EMP stochastic programming models, the model consists of three parts: the [core model](#), the [EMP annotations](#) and the [dictionary](#) with output-handling information. As usual, the core model is defined as a deterministic model and the specifications relating to the stochastic structure of the problem are written to the file `emp.info`. In the EMP annotations, the EMP keyword `randvar` is used to declare a parameter from the core model as a random variable. The keyword is followed by `om`, the random variable, and the distribution. The EMP keyword `discrete` indicates that we have a discrete distribution. The discrete distribution is specified via probability-numerical value pairs. Note that continuous distributions are also possible. See section [Random Variables with Continuous Distributions](#) for more information. The second line in the EMP annotations starts with the EMP keyword `chance` followed by the equation `e1` and a probability. The specification means that the constraints `e1` must hold for at least 75% of all scenarios. We can verify that this requirement has been enforced by checking in the listing file the level value of the constraint `e1_l`. We will see that in the first scenario the constraint was violated, but is was satisfied in all other scenarios.

Observe that the EMP keyword `chance` allows for an optional specification that is related to a penalization factor for constraints that are violated. This topic is discussed in section [Penalizing Violations of Chance Constraints](#) below.

Note

Currently, there are no stages in stochastic problems with chance constraints, unlike in stochastic problems with recourse.

As the problem is solved as a MIP, it is important that the options [OptCA](#) and [OptCR](#) are assigned appropriate values.

Note that the default value of M is $1e7$ for the solver Lindo. To customize this and set it to, e.g., 1000 instead, one could insert the following five lines before the solve statement:

```

option emp = lindo;
$onecho > lindo.opt
STOC_BIGM 1e3
$offecho
sc.optfile = 1;

```

For DE the default value of M is 10000 and it could be changed to 1000 in a similar way as seen above for Lindo:

```

option emp = de;
$onecho > de.opt
ccreform bigM 1e3
$offecho
sc.optfile = 1;

```

Note that `ccreform` is a DE option. This option allows to specify two alternative solution strategies: a reformulation using a convex hull and a reformulation using indicator variables and indicator constraints. The following line indicates that a convex hull with $M = 1000$ and $\epsilon = 0.00001$ is to be used:

```
ccreform cHull 1e3 1e-6
```

For indicator variables and constraints, the following line is used:

```
ccreform indic
```

Note that currently only the solver CPLEX supports indicator variables, so the resulting reformulated problem has to be solved with CPLEX.

4.47.11.3.3 Examples with Multiple Chance Constraints Stochastic problems with multiple chance constraints have two different forms: problems with *joint* chance constraints and problems with *multiple individual* chance constraints. In problems with joint chance constraints the constraints all have to be satisfied simultaneously with probability p . In problems with multiple individual chance constraints each constraint carries its own risk tolerance. We illustrate with two examples.

4.47.11.3.3.1 Joint Chance Constraints We illustrate joint chance constraints by extending the example [above](#) by one constraint resulting in a problem with two chance constraints:

$$\begin{aligned} \text{Min} \quad & x_1 + x_2 \\ \text{s.t.} \quad & P(\omega_1 x_1 + x_2 \geq 7; \omega_2 x_1 + 3x_2 \geq 12) \geq 0.6, \quad (\omega_1, \omega_2) \in \Omega \\ & x_1, x_2 \geq 0, \end{aligned} \quad (52)$$

where

$$\Omega = \{(1, 1), (1, 2), (1, 3), (2, 1), (2, 2), (2, 3), (3, 1), (3, 2), (3, 3), (4, 1), (4, 2), (4, 3)\} \quad (4.27)$$

and

$$\pi^k = \pi(\omega_1, \omega_2) = \frac{1}{12} \quad \text{for all } (\omega_1, \omega_2) \in \Omega. \quad (4.28)$$

Note that both random variables follow discrete uniform distributions, ω_1 has four realizations and ω_2 has three realizations. Thus we have 12 scenarios that are all equally likely. The MIP equivalent takes the following form:

$$\begin{aligned} \text{Min} \quad & x_1 + x_2 \\ \text{s.t.} \quad & 1x_1 + x_2 \geq 7 - M(1 - y_1) \\ & 1x_1 + 3x_2 \geq 12 - M(1 - y_1) \\ & 2x_1 + x_2 \geq 7 - M(1 - y_2) \\ & 1x_1 + 3x_2 \geq 12 - M(1 - y_2) \\ & \vdots \\ & 4x_1 + x_2 \geq 7 - M(1 - y_{12}) \\ & 3x_1 + 3x_2 \geq 12 - M(1 - y_{12}) \\ & cc_1 = 1 - \sum_k \pi^k y_k, \quad k = 1, \dots, 12, \pi^k = \frac{1}{12} \\ & x_1, x_2 \geq 0 \\ & 0 \leq cc_1 \leq (1 - 0.6) \\ & y_k \in (0, 1). \end{aligned} \quad (53)$$

Note that the first set of constraints covers the 12 scenarios, where each scenario has two constraints. The other constraints are similar to those introduced in [the previous model](#).

The problem can be modeled with GAMS EMP as follows:

```
* Core Model
Positive Variables x1, x2;
Variables          z;

Scalars om1, om2;
om1 = 1;
om2 = 1;
```

```

Equations obj, e1, e2;

obj..    z =e= x1 + x2;
e1..     om1*x1 +    x2 =g= 7;
e2..     om2*x1 + 3*x2 =g= 12;

Model sc / all /;

* EMP Annotations
File emp / '%emp.info%' /;
put emp '* problem %gams.i%' /;
$onput
randvar om1 discrete 0.25 1 0.25 2 0.25 3 0.25 4
randvar om2 discrete 0.3333 1 0.3334 2 0.3333 3
chance e1 e2 0.6
$offput
putclose emp;

* Dictionary
Set scen "scenarios" / s1*s12 /;
Parameters  s_om1(scen)
             s_om2(scen)
             x1_l (scen)
             x2_l (scen)
             e1_l (scen)
             e2_l (scen);

Set dict / scen .scenario. ''
          om1  .randvar .s_om1
          om2  .randvar .s_om2
          x1   .level   .x1_l
          x2   .level   .x2_l
          e1   .level   .e1_l
          e2   .level   .e2_l/;

solve sc min z use emp scenario dict;
display s_om1, s_om2, x1_l, x2_l, e1_l, e2_l;

```

In the [EMP annotations](#), the line `chance e1 e2 0.6` specifies that in at least 60% of all scenarios both constraints `e1` and `e2` must be satisfied at the same time. There are a total of 12 scenarios, hence both constraints must be satisfied in at least 8 scenarios (i.e. $12 \times 0.6 = 7.2 \leq 8$). We can verify that this requirement has been enforced by checking in the listing file the level values of the constraints, `e1_l` and `e2_l`. Indeed, in the optimal solution both constraints hold in scenarios 4 to 12, meaning that there are 9 scenarios that satisfy both inequalities.

4.47.11.3.3.2 Individual Chance Constraints In stochastic problems with individual chance constraints there is no correlation between the probabilities of the rows of the matrix A . Hence problem (47) takes the following form:

$$\begin{aligned}
 & \text{Min}_x && c^T x \\
 & \text{s.t.} && P(A_i x \leq b_i) \geq p_i, \quad i = 1, \dots, m \\
 & && x \geq 0.
 \end{aligned} \tag{54}$$

To illustrate, we use an extended version of the the example from the [previous section](#) and replace the joint chance constraints by individual chance constraints:

$$\begin{aligned}
 \text{Min} \quad & x_1 + x_2 \\
 \text{s.t.} \quad & P(\omega_1 x_1 + x_2 \geq 7) \geq 0.75, & \omega_1 \in \Omega_1 = \{1, 2, 3, 4\} \\
 & P(\omega_2 x_1 + 3x_2 \geq 12) \geq 0.6, & \omega_2 \in \Omega_2 = \{1, 2, 3\} \\
 & P(\omega_1 x_1 + \omega_2 x_2 \geq 10) \geq 0.5, & (\omega_1, \omega_2) \in \Omega_1 \times \Omega_2 = \Omega \\
 & x_1, x_2 \geq 0.
 \end{aligned} \tag{55}$$

Note that Ω is defined as in (52) above, we have again 12 scenarios, each with probability $\pi^k = \frac{1}{12}$. However, in this example, the first inequality must hold in 9 out of 12 scenarios ($0.75 \times 12 = 9$), the second inequality must hold in 8 out of 12 inequalities ($0.6 \times 12 = 7.2 \leq 8$) and the third inequality must hold in 6 out of 12 scenarios. Note further, that we may have four types of scenarios: scenarios where all constraints are violated, scenarios where two constraints are violated, scenarios where one constraint is violated and scenarios where all three constraints are satisfied. The only condition is that for each constraint there is the respective number of scenarios where the constraint is satisfied. Observe that the random data in the third inequality is a combination of the random data of the first two inequalities. The inequalities for the scenarios are given below:

$$\begin{aligned}
 k = 1 : \quad & \omega_1^1 = 1, \omega_2^1 = 1 & \omega_1^1 x_1 + x_2 &\geq 7 \\
 & & \omega_2^1 x_1 + 3x_2 &\geq 12 \\
 & & \omega_1^1 x_1 + \omega_2^1 x_2 &\geq 10 \\
 k = 2 : \quad & \omega_1^2 = 1, \omega_2^2 = 2 & \omega_1^2 x_1 + x_2 &\geq 7 \\
 & & \omega_2^2 x_1 + 3x_2 &\geq 12 \\
 & & \omega_1^2 x_1 + \omega_2^2 x_2 &\geq 10 \\
 & \vdots & & \\
 k = 12 : \quad & \omega_1^{12} = 4, \omega_2^{12} = 3 & \omega_1^{12} x_1 + x_2 &\geq 7 \\
 & & \omega_2^{12} x_1 + 3x_2 &\geq 12 \\
 & & \omega_1^{12} x_1 + \omega_2^{12} x_2 &\geq 10
 \end{aligned} \tag{56}$$

The MIP equivalent follows:

$$\begin{aligned}
 \text{Min} \quad & x_1 + x_2 \\
 \text{s.t.} \quad & 1x_1 + x_2 \geq 7 - M(1 - y_1^1) \\
 & 1x_1 + 3x_2 \geq 12 - M(1 - y_1^2) \\
 & 1x_1 + 1x_2 \geq 10 - M(1 - y_1^3) \\
 & 2x_1 + x_2 \geq 7 - M(1 - y_2^1) \\
 & 1x_1 + 3x_2 \geq 12 - M(1 - y_2^2) \\
 & 2x_1 + 1x_2 \geq 10 - M(1 - y_2^3) \\
 & \vdots \\
 & 4x_1 + x_2 \geq 7 - M(1 - y_{12}^1) \\
 & 3x_1 + 3x_2 \geq 12 - M(1 - y_{12}^2) \\
 & 4x_1 + 3x_2 \geq 10 - M(1 - y_{12}^3) \\
 & cc_1 = 1 - \sum_k \pi^k y_k^1, \quad k = 1, \dots, 12, \quad \pi^k = \frac{1}{12} \\
 & cc_2 = 1 - \sum_k \pi^k y_k^2, \quad k = 1, \dots, 12, \quad \pi^k = \frac{1}{12} \\
 & cc_3 = 1 - \sum_k \pi^k y_k^3, \quad k = 1, \dots, 12, \quad \pi^k = \frac{1}{12} \\
 & x_1, x_2 \geq 0 \\
 & 0 \leq cc_1 \leq (1 - 0.75) \\
 & 0 \leq cc_2 \leq (1 - 0.6) \\
 & 0 \leq cc_3 \leq (1 - 0.5) \\
 & y_k^j \in (0, 1).
 \end{aligned} \tag{57}$$

As expected, there are three constraints for every scenario. Note that we introduced three new variables, cc_1 , cc_2 and cc_3 and three corresponding constraints. Each of the variables has a different range reflecting the different probabilities with which a constraint may be violated.

The core model of the GAMS code is very similar to the core model with joint chance constraints. We just add the third inequality:

```
Equations obj, e1, e2, e3;
```

```
obj..    z =e= x1 + x2;
e1..    om1*x1 + x2 =g= 7;
e2..    om2*x1 + 3*x2 =g= 12;
e3..    om1*x1 + om2*x2 =g= 10;
```

There is a slight modification in the annotations:

```
File emp / '%emp.info%' /;
put emp '* problem %gams.i%' /;
$onput
randvar om1 discrete 0.25 1 0.25 2 0.25 3 0.25 4
randvar om2 discrete 0.3333 1 0.3334 2 0.3333 3
chance e1 0.75
chance e2 0.6
chance e3 0.5
$offput
putclose emp;
```

Observe that we have three lines that start with the [EMP keyword](#) **chance**: every constraint is listed separately with its respective probability.

Note

In case one constraint has to be satisfied in all scenarios (so it is strictly speaking not a chance constraint), then it has to be listed with probability 1.0.

An overview of which constraints are satisfied in which scenarios in the optimal solution is given in the following table:

Scenarios	1	2	3	4	5	6	7	8	9	10	11	12
Scenarios where e1 is satisfied				x	x	x	x	x	x	x	x	x
Scenarios where e1 is satisfied		x	x		x	x		x	x		x	x
Scenarios where e1 is satisfied						x	x	x	x	x	x	x

Table 7: Overview of constraint satisfaction per scenario

Observe that all constraints are satisfied in as many scenarios as required and there are scenarios where all three constraints are satisfied ($k = 6, 8, 9, 11, 12$), scenarios where only two constraints are satisfied ($k = 5, 7, 10$), scenarios where only one constraint is satisfied ($k = 2, 3, 4$) and one scenario where all constraints are violated ($k = 1$).

The choice whether joint or individual chance constraints should be used depends on the system being modeled. Both approaches have their own advantages. Individual chance constraints are weaker since not

all constraints have to be satisfied at the same time. This can be clearly observed in the optimal solution for example (55). The objective value is 5.20 in the model with joint chance constraints and 4.75 in the model with individual chance constraints (assuming that each constraint is satisfied in 60% of all scenarios). As it is a minimizing problem, the model with individual chance constraints yields the better result. However, in this solution we have only 6 scenarios where both constraints are simultaneously satisfied while each constraint is satisfied in eight scenarios in total for the joint chance constraint formulation, as required.

4.47.11.3.4 Penalizing Violations of Chance Constraints The EMP framework provides the syntax for a penalty factor for each scenario that violates one or more constraints. In the example with joint constraints above, the EMP annotations could be modified in the following way:

```
$onput
randvar om1 discrete 0.25 1 0.25 2 0.25 3 0.25 4
randvar om2 discrete 0.3333 1 0.3334 2 0.3333 3
chance e1 e2 0.6 3
$offput
```

Note that we added the number 3 at the end of the last line. This new entry represents a penalty factor. Recall that the MIP equivalent (53) takes the following form:

$$\begin{aligned}
 \text{Min} \quad & z = x_1 + x_2 \\
 \text{s.t.} \quad & 1x_1 + x_2 \geq 7 - M(1 - y_1) \\
 & 1x_1 + 3x_2 \geq 12 - M(1 - y_1) \\
 & \vdots \\
 & 4x_1 + x_2 \geq 7 - M(1 - y_{12}) \\
 & 3x_1 + 3x_2 \geq 12 - M(1 - y_{12}) \\
 & cc_1 = 1 - \sum_k \pi^k y_k, \quad k = 1, \dots, 12, \quad \pi^k = \frac{1}{12} \\
 & x_1, x_2 \geq 0 \\
 & 0 \leq cc_1 \leq (1 - 0.6) \\
 & y_k \in (0, 1).
 \end{aligned} \tag{58}$$

Observe that the probability with which the constraints are allowed to be violated is stored in the variable cc_1 . Introducing a penalty factor or weight w has the effect that the term $(w \times cc_1)$ is added to the objective function:

$$z = x_1 + x_2 + w \times cc_1 = x_1 + x_2 + 3 cc_1 \tag{4.29}$$

Similarly, we could add weights in the [example with individual chance constraints](#):

```
chance E1 0.75 5
chance E2 0.6 6
chance E3 0.5 7
```

Given these annotations, we obtain the following objective function in the MIP equivalent:

$$z = x_1 + x_2 + 5 cc_1 + 6 cc_2 + 7 cc_3. \tag{4.30}$$

Penalty terms can be useful to explore sensitivities to slight changes.

Note

Like in the context of [soft constraints](#), the penalty term is *added* in *minimization* problems and *subtracted* in *maximization* problems.

Moreover, the probability expression cc_1 in the MIP equivalent may be used as a variable in the original model. For example, in the joint chance constraints problem [above](#), we could introduce a new variable, $viol$, in the objective function:

$$\text{Min } z = x_1 + x_2 + 3 * viol \quad (4.31)$$

Then we write the chance constraint specification in the EMP annotations as follows:

```
chance E1 E2 0.6 viol
```

The addition of the variable $viol$ as penalty factor causes cc_1 to be replaced by $viol$ in the MIP equivalent. Thus we have:

$$viol = 1 - \sum_k \pi^k y_k, \quad k = 1, \dots, 12, \quad \pi^k = \frac{1}{12}, \quad viol \in [0, 0.4]. \quad (4.32)$$

Note that the corresponding model is equivalent to the joint chance constraints model with penalty factor 3 with which we started this subsection.

4.47.11.3.5 EMP Syntax for Chance Constraints The general syntax of the [EMP annotations](#) used to specify stochastic problems with chance constraints is as follows:

```
[randvar rv discrete prob val {prob val}]
[randvar rv distr par {par}]
[jrandvar rv rv {rv} prob val val {val} {prob val val {val}}]
chance equ {equ} [holds] minRatio [weight|var]
{chance equ {equ} [holds] minRatio [weight|var]}
```

The first three lines present three ways to specify random variables. The syntax and logic is the same as in stochastic problems with recourse, see [above](#) for details. Note that at least one random variable has to be specified. The [EMP keyword chance](#) is used to define the constraint(s) that only have to hold for a certain ratio of the possible outcomes. This ratio is given with the number `minRatio` ($0 \leq \text{minRatio} \leq 1$). The keyword `holds` is optional and does not affect the solver. The remaining specifications are optional and relate to the [penalization of chance constraints that are violated](#). If `weight` is defined, the violation of a chance constraint will be penalized in the objective function (`weight × violationRatio`). Alternatively, if the name of a variable of the model (`var`) is specified, the violation will be multiplied by the value of this variable instead of the fixed multiplier `weight`.

In this section we have introduced various versions of problems with chance constraints with simple examples. For a more complex example, see the farming model [\[KILOSAFARM\]](#) in the GAMS EMP Model Library.

4.47.12 EMP Keywords

Some words act as keywords in the context of the [EMP annotations](#) in the file `emp.info`, but they are *not* [GAMS reserved words](#), i.e. they are not keywords in the GAMS code apart from the EMP annotations. In this section we present an overview of all GAMS EMP keywords, ordered according to the type of programming where they are used.

4.47.12.1 GAMS EMP Keywords for Soft Constraints

EMP Keyword	Description
abs	Penalty function : absolute value of the equation.
adjustequ	Indicates that the specification(s) that follow relate to equations that are converted from constraints to penalty terms in the objective function.
maxz	Penalty function : the maximum of the equation and zero. An example is given above .
sqr	Penalty function : least squares applied to the equation. An example is given above .

4.47.12.2 GAMS EMP Keywords for Variational Inequalities

EMP Keyword	Description
VI	Indicates that the specifications that follow are a variational inequality. See the discussion of EMP specifications for VI and the example above .
QVI	Indicates that the specifications that follow are a quasi-variational inequality. See the discussion of EMP specifications for QVI and the example above .

4.47.12.3 GAMS EMP Keywords for Equilibrium Problems

EMP Keyword	Description
dualvar	See below .
Equilibrium	Indicates that the specifications that follow define the structure of an equilibrium problem. For examples, see sections Equilibrium Problems with EMP: A Simple Example and Equilibrium Problems with EMP: Example with Dual Variables . The general syntax of EMP annotations for equilibrium problems is introduced in section EMP Syntax for Equilibrium Problems .
implicit	Specifies a shared variable and its defining constraint. For details, see section Equilibrium Problems with Shared Variables .
max	This keyword is followed by the objective variable, the decision variable(s) and the equation(s) of the <i>maximization</i> problem of one agent.
min	This keyword is followed by the objective variable, the decision variable(s) and the equation(s) of the <i>minimization</i> problem of one agent.
VI	Indicates that the specifications that follow define a VI , as in this example .
VIso1	Specifies that the equation that follows is a shared constraint and prompts the EMP framework to use the MCP reformulation where a variational inequality is associated with the shared constraint. For more information and an example, see section Equilibrium Problems with Shared Constraints .

4.47.12.4 GAMS EMP Keywords for Embedded Complementarity Systems

EMP Keyword	Description
DualEqu	This keyword is followed by an equation-variable pair. It establishes a complementarity relationship between an external equation and the named variable of the model. An example is given above . See also the spatial price equilibrium model [HARK-MONOP] .
DualVar	This keyword is followed by a variable-equation pair. It specifies that the variable is the dual of the equation. Examples are discussed in sections Equilibrium Problems with EMP: Example with Dual Variables and Embedded Complementarity Systems .

Note that problems with embedded complementarity systems can be recast as equilibrium problems. Details are given in section [Embedded Complementarity Systems](#).

4.47.12.5 GAMS EMP Keywords for Bilevel Programming

EMP Keyword	Description
bilevel	Indicates that the specifications that follow relate to a bilevel programming problem. The keyword is followed by the decision variable(s) of the upper-level problem and the definitins(s) of the lower-level problem(s). For examples and more details, see section Bilevel Programs .
dualvar	See above .
max	This keyword is followed by the objective variable, the decision variable(s) and the equation(s) of the <i>maximization</i> problem of one agent.
min	This keyword is followed by the objective variable, the decision variable(s) and the equation(s) of the <i>minimization</i> problem of one agent, as in this example .
VI	Indicates that the specifications that follow define a VI , as in this example .

4.47.12.6 GAMS EMP Keywords for Disjunctive Programming

EMP Keyword	Description
bigM	Indicates that the big M reformulation method shall be used.
chull	Indicates that a convex hull shall be used for the reformulation. Note that this is the default method.
default	Indicates that the specification that follows is the reformulation method.
disjunction	Indicates that the specification that follows is a disjunction. For a discussion of the general syntax following this keyword, see above .
indic	Indicates that indicator constraints shall be used as reformulation method.
star (*)	The symbol * will be replaced by internal default binary variables, thus explicit binary variables that model the Boolean variables are not needed. Note that default binary variables may only be used if there are no logic equations in the model. For an example and more details, see above .

4.47.12.7 GAMS EMP Keywords for Stochastic Programming

EMP Keyword	Description
chance	Defines individual or joint chance constraints .
cvar	Synonym to cvarup .
cvarlo	This keyword assigns a variable to have the value $\underline{CVaR}_\alpha$, where α is a scalar that represents the confidence level for the Conditional Value at Risk. Note that cvarlo refers to the left tail of the distribution. For more details and examples, see section Conditional Value at Risk (CVaR) .
cvarup	This keyword assigns a variable to have the value $\overline{CVaR}_\alpha$. α is a scalar that represents the confidence level for the Conditional Value at Risk. Note that cvarup refers to the right tail of the distribution.
discrete	Indicates that the specification that follows is the discrete distribution of one or more random variables.
ExpectedValue	This keyword is used to state that a variable is the expected value of a random variable.

EMP Keyword	Description
jrandvar	This keyword is used to define discrete random variables that are <i>jointly</i> distributed. At least two random variables must be named. For an example, see the news vendor model [NBDISJOINT].
randvar	This keyword declares that a parameter of the model is in fact a stochastic random variable. The keyword is followed by the name of the parameter and details about the probability distribution (discrete or parametric). A list of all supported parametric distributions is given in Table 4.
sample	This keyword allows users to customize the size of the sample of one or more random variables from a continuous distribution and - optionally - to determine the variance reduction method to be used. An example and further details are given above. Note that without a valid LINDO license this is limited to the Normal and Binomial distributions with a maximum sample size of 10.
setSeed	This keyword sets the seed for the random number generator of the sampling routines that are called via the keyword sample . If setSeed is used in EMP annotations, the seed will be set once before all samples will be generated. Note that a valid LINDO license is required to use this keyword.
stage	This keyword is followed by a number and the names of the random variables, variables and equations that are assigned to the respective stage. Stage 1 is the default stage for all random variables, variables and equations that are not assigned a stage explicitly except for objective equation and variable. Their default stage is the highest stage in the model.
var	Synonym to varup .
varlo	This keyword assigns a variable to have the value VaR_{α} , where α is a scalar that represents the percentile of the Value at Risk. Note that varlo refers to the left tail of the distribution. For more details and examples, see section Value at Risk (VaR).
varup	This keyword assigns a variable to have the value $\overline{VaR}_{\alpha}$, where α is a scalar that represents the percentile of the Value at Risk. Note that varup refers to the right tail of the distribution and α typically equals 0.95 or 0.9. For further information, see section Value at Risk (VaR).

Currently, three GAMS solvers can be used to solve stochastic programming models with EMP: DE, DECIS, and LINDO. Not all keywords mentioned above are supported by all those solvers. The following table specifies which keywords can be used with which solvers. The keywords not mentioned in the table are supported by all solvers mentioned.

	DE	DECIS	LINDO
chance	✓		✓
jrandvar	✓	✓	✓
randvar (discrete)	✓	✓	✓
randvar (parametric)	✓		✓
sample	✓		✓
setSeed			✓
var	✓		
cvar	✓		
ExpectedValue	✓		

Table 8: Solver capabilities

Further information about these solvers can be found in the corresponding solver manuals. The stochastic programming options for the solver LINDO might be of particular interest.

4.48 Accessing Model Libraries

Professor Paul Samuelson is fond of saying that he hopes each generation economists will be able to "**stand on the shoulders**" of the previous generation. The library of models included with the GAMS system is a reflection of this desire. We believe that the quality of modeling will be greatly improved and the productivity of modelers enhanced if each generation can stand on the shoulders of the previous generation by beginning with the previous models and enhancing and improving them. The Model Libraries includes a large number of models, collectively organized as

- **GAMS Model Library** - includes GAMS models representing interesting and sometimes classic problems, ranged from production and shipment by firms, investment planning, cropping patterns in agriculture, operation of oil refineries and petrochemical plants, macroeconomics stabilization, applied general equilibrium, international trade in aluminum and in copper, water distribution networks, and many more.
- **GAMS Test Library** - includes GAMS models developed for testing and quality control, both for the GAMS base module and the many solvers distributed with the GAMS system.
- **GAMS Data Utilities Library** - includes GAMS models demonstrating various utilities to interface GAMS with other tools and applications such as spreadsheets and database interface.
- **GAMS EMP Library** - includes GAMS Extended Mathematical Programming (EMP) models that illustrate and test the capabilities of GAMS/EMP.
- **GAMS API Library** - includes GAMS Models used as scripts to compile and execute application programs in various programming languages interfacing to GAMS.
- **FIN Library** - includes GAMS practical financial optimization models described in the book *Practical Financial Optimization: Decision Making for Financial Engineers* by Consiglio, Nielsen and Zenios,
- **NOA Library** - includes GAMS nonlinear optimization applications models based on the book *Nonlinear Optimization Applications Using the GAMS Technology* by Neculai Andrei.
- **PSOPT Library** - includes GAMS optimization models based on the book *Power System Optimization Modelling in GAMS* by Alireza Soroudi.

The models included have been selected not only because they collectively provide strong shoulders for new users to stand on, but also because they represent interesting and sometimes classic problems. For example the trade-off between consumption and investment is richly illustrated in the Ramsey problem, which can be solved using nonlinear programming methods. Examples of other problems included in the library are production and shipment by firms, investment planning in time and space, cropping patterns in agriculture, operation of oil refineries and petrochemical plants, macroeconomics stabilization, applied general equilibrium, international trade in aluminum and in copper, water distribution networks, and relational databases.

Another criterion for including models in the library is that they illustrate the modeling capabilities GAMS offers. For example, the mathematical specification of cropping patterns can be represented handily in GAMS. Another example of the system's capability is the style for specifying initial solutions as starting points in the search for the optimal solution of dynamic nonlinear optimization problems.

Finally, some models have been selected for inclusion because they have been used in other modeling systems. Examples are network problems and production planning models. These models permit the user to compare how problems are set up and solved in different modeling systems.

Most of the models have been contributed by GAMS users. The submission of new models is encouraged. If you would like to see your model in a future release of the library, please send the model and associated documents and reports to GAMS Development Corporation.

4.48.1 Usage

4.48.1.1 Command Line Approach

One way to access the library is through command line. The following commands copy a model from the library directory into the current directory.

Command	Library to access
<code>gamslib</code>	GAMS Model Library
<code>testlib</code>	GAMS Test Library
<code>datalib</code>	GAMS Data Library
<code>emplib</code>	GAMS EMP Library
<code>apilib</code>	GAMS API Library
<code>finlib</code>	FIN Library
<code>noalib</code>	NOA Library
<code>psoptlib</code>	PSOPT Library

Take the command `gamslib` for an example, if you enter `gamslib` without any parameters, the command syntax will be displayed as shown below:

```
> gamslib modelname [target]
```

or

```
> gamslib modelnum [target]
```

where

- `modelname` is the modelname
- `modelnum` is the model sequence number, and
- `target` is the target file name.

If the target file name is not provided, the default is `modelname.gms`. The file will be automatically copied into the current working directory. For example, the **[TRANSPORT]** model from the **GAMS Model library** has sequence number 1 and could be copied in any of the following ways.

To copy **[TRANSPORT]** model file to target file `trnsport.gms` under the current directory:

```
> gamslib trnsport
```

```
> gamslib 1
```

To copy **[TRANSPORT]** model file to target file `myname.gms` under the current directory:

```
> gamslib trnsport myname
```

```
> gamslib 1 myname
```

The other commands have similar usage to `gamslib` command.

4.48.1.2 IDE Approach

A convenient way (Windows only) to access the model library is from within the **GAMS IDE** by going through : Model Libraries.

Invoking the GAMS Model Library menu will pop up the window in following screen.

The grid filled with model names is a scrollable list of files with column entries describing file attributes. At the bottom is a more lengthy description of the file highlighted. In turn double clicking in a row causes the file to be loaded in the IDE for editing and into your project directory. Simultaneously all files it includes and other files the library creator nominated are placed in the project directory.

There are several features of this manager that merit description

- The window contains a search box as in the blue box below. When one types an entry into that box the window automatically scrolls forward to a file that contains the typed text somewhere in it. For example typing in the string "chem" causes the screen below to appear

where the ALYKL command is the first one that contains the string "chem". If one wants to find the next occurrence of the string one can press the down arrow key while the up arrow reveals the previous one.

- The gray bar at the top of the grid allows one to alter the tabular sort order. By clicking the mouse on the gray bar one changes that order. For example touching the word Type causes the files to be sorted by model type as illustrated below.

Name	Application Area	Type +	Contributor	Description
CAMCNS	Applied General Equilibrium	CNS	Condon, T	Cameroon General Equilibrium Model Using CNS
GANCNS	Applied General Equilibrium	CNS	Mitra, P	Macro-Economic Framework for India - CNS
GANCNSX	Applied General Equilibrium	CNS	Mitra, P	Macro-Economic Framework for India - Tracking CNS
KORCNS	Applied General Equilibrium	CNS	Lewis, J	General Equilibrium Model for Korea - CNS
AIRSP2	Stochastic Programming	DECIS	Dantzig, G B	Aircraft Allocation - stochastic optimization with DECIS
APL1P	Stochastic Programming	DECIS	Infanger, G	Stochastic Programming Example for DECIS
APL1PCA	Stochastic Programming	DECIS	Infanger, G	Stochastic Programming Example for DECIS
FARM	Stochastic Programming	DECIS	Birge, J R	The Farmer's Problem formulated for DECIS
PRODSP2	Stochastic Programming	DECIS	King, A J	Stochastic Programming Example - reformulated for DECIS
LINEAR	Econometrics	DNLP	Bracken, J	Linear Regression with Various Criteria
WATER	Engineering	DNLP	Brooke, A	Design of a Water Distribution Network
REPAY	Finance	GAMS	GAMS Develop	Repayment Factors for Loans
CALENDAR	GAMS Language Features	GAMS	GAMS Develop	Calendar Function Examples
GAMSHM	GAMS Language Features	GAMS	GAMS Develop	HTML generation of model library
GAMSUTIL	GAMS Language Features	GAMS	GAMS Develop	Generates some useful files from the Model Library

The column sorted on is marked with a + if in forward order and a minus if in reverse order.

The sort order also uses a secondary sort key where it remembers the previous columns you have sorted on. Consequently if you first click on Name then Type you the files will be arranged by alphabetical order of their names under a problem type. But if you sorted first on Application Area then most recently on Type they would be organized by Application Area under each problem type.

- A left click with the mouse on a file name causes its description to be placed in the text box at the bottom. A double click loads the file into the IDE.

Name	Application Area +	Type	Contributor	Description
AGRESTE	Agricultural Economics	LP	Kutcher, G P	Agricultural Farm Level Model of NE Brazil
CHINA	Agricultural Economics	LP	Wiens, T B	Organic Fertilizer Use in Intensive Farming
DEM01	Agricultural Economics	LP	Kutcher, G P	Simple Farm Level Model

SARF	Agricultural Economics	LP	Husain, T	Farm Credit and Income Distribution Model
CHAMCF	Agricultural Economics	NP	Bracken, J	Chance Constrained Feed Mix Problem

North-East Brazil Regional Agricultural Model (NEBRAZIL, SEQ=87)

This model was used to study the root causes of stagnation and poverty in the rural economy of the northeast of Brazil. It was used to quantify the effects of policy and project intervention.

Reference:
Kutcher, G P, and Scandizzo, P L, The Agricultural Economy of Northeast Brazil. The Johns Hopkins University Press, Baltimore and London, 1981.

- A right click with the mouse brings up a menu box.

NEBRAZIL	Agricultural Economics	LP	Kutcher, G P	North-East Brazil Regional Agricultural Model
PAKLIVE	Agricultural Economics	LP	World Bank	Pakistan Punjab Livestock Model
SARF	Agricultural Economics	LP	Husain, T	Farm Credit and Income Distribution Model
CHAMCF	Agricultural Economics	NP	Bracken, J	Chance Constrained Feed Mix Problem

If one chooses the view model choice the GAMS code is placed in the box where the description appeared with a gray background.

NEBRAZIL	Agricultural Economics	LP	Kutcher, G P	North-East Brazil Regional Agricultural Model
PAKLIVE	Agricultural Economics	LP	World Bank	Pakistan Punjab Livestock Model
SARF	Agricultural Economics	LP	Husain, T	Farm Credit and Income Distribution Model
CHAMCF	Agricultural Economics	NP	Bracken, J	Chance Constrained Feed Mix Problem

```

Set zz      zones / west , sertao , southeast , east , agreste /

z(zz)      zone of choice for submodel solution

zr(zz)     zone with rotation restrictions / sertao , west /

zrc(zz)    zones for which rotation constraint is binding / west , sertao /

```

Another right click will bring up the box again and the view model choice can be unclicked.

- You may change column widths, allocation of top and bottom screen parts and window size just as in other programs through use of the mouse. The IDE will remember **some but not all** of your choices.
- Users may define their own library by using a GLB file, see [Creating a User Library for use in the IDE](#) and [Example](#) by Bruce A. McCarl.

4.49 Mathematical Programming System for General Equilibrium analysis (MPSGE)

- [Introduction to MPSGE](#)
- [MPSGE Models in GAMS](#)
- [Demand Theory and General Equilibrium: An Intermediate Level Introduction to MPSGE](#)
- [Constant Elasticity of Substitution Functions: Some Hints and Useful Formulae](#)
- [A Library of Small Examples for Self-Study](#)

- [Kevin O'Rourke: CGE and Economic History](#)
- [Linking Implan Social Accounts to MPSGE](#)
- [A partial list of publications based on MPSGE](#)
- The MPSGE guide is also available as [PDF](#).

4.49.1 Introduction to MPSGE

MPSGE is a language used for formulating and solving Arrow–Debreu economic equilibrium models and exists as a subsystem within GAMS. The name stands for ‘mathematical programming system for general equilibrium’. MPSGE provides a short-hand non-algebraic representation for the systems of nonlinear inequalities which underly general equilibrium models. The MPSGE framework is based on nested constant elasticity of substitution utility and production functions. The data requirements for a model include share and elasticity parameters, endowments, and tax rates for all the consumers and production sectors in the model. These may or may not be calibrated from a consistent benchmark equilibrium dataset.

The main benefit of using MPSGE is that modelers are released from having to write the equations of the model and the calibrated demand and supply functions. Experience shows that even computing the parameters of the functions is error-prone. The tabular input format of MPSGE facilitates a compact, non-algebraic representation of the equations of a model. Thus algebraic tedium and the scope for programming errors are reduced, and more attention can be paid to economic interpretation and testing of alternative formulations.

This chapter offers an introduction to MPSGE for users who are familiar with GAMS. For more information on MPSGE and details on more advanced features, see [207] and [168]. In addition, a library of small examples for self-study is available [here](#) .

This chapter is organized as follows. We start with an overview of some [basic economic ideas](#) and general remarks on [specifying an MPSGE model](#). Next, we introduce a first [simple example](#). Then we demonstrate how [intermediate demand and joint production](#) are modeled with MPSGE. We follow with a third model that features a [small open economy](#) and also includes taxes on inputs and outputs, labor-leisure choice, classical unemployment, and nested demand functions. We conclude the chapter with an overview of [MPSGE keywords](#) and the syntax for specifying functions, some other features like [domain restrictions on variable declarations](#), and a few brief comments on [MPSGE-specific output](#) in the GAMS listing file. Note that a full version of all MPSGE models that are discussed, including standard GAMS versions, are given in the [Appendix](#).

4.49.1.1 Some Basic Economic Ideas

MPSGE models are based on the following economic ideas. In each model there are multiple interacting agents, where each agent solves an optimization problem. For example, consumers maximize utility subject to their budget constraint, and producers minimize their cost given available technology. Agent interactions are mediated by markets and prices and the optimal solution is an equilibrium where prices and activity levels have adjusted so that markets for produced goods and input factors clear. In equilibrium, each agent cannot do better by altering their behavior (given the constraints they face). In this section we give more details on these basic economic ideas. In particular, we offer brief introductions to [consumer demand theory](#), [producer supply theory](#) and [general economic equilibrium](#).

4.49.1.1.1 Consumer Demand Theory Consumer choice is modeled using an optimization paradigm: consumers form a consumption bundle which maximizes welfare subject to a budget constraint. As an abstract notion, this seems plausible, but certain details must be dealt with to provide an operational application of the idea.

Consider the following example. Thomas lives in Ann Arbor where he spends 30% on housing and the rest of his income on other goods. This information is essentially an observation of a *benchmark equilibrium*, consisting of the prevailing prices and quantities of goods demanded. Now, Thomas has an employment offer in Berlin which pays 50% more than he currently earns, but he is hesitant to take the job since rental rates in Berlin are three times higher than in Ann Arbor. The question is: On purely economic grounds, should he move?

Thomas' choices are illustrated below. Point *a* represents the benchmark point, where he spends the amount H_a on housing in Ann Arbor. Point *b* represents a potential trade-off between housing and other goods in Berlin, where he spends a lower percentage of his income on housing and more on other goods.

Figure 4.3 Thomas' Choices

Whether Thomas derives the same welfare from the choices represented by point *b* like those represented by point *a* depends on the *elasticity of substitution*. The elasticity of substitution is the willingness to exchange some amount of one good for more of the other good. The three curves in the figure above represent three elasticities of substitution. Note that the less convex (flatter) the curve is, the higher is the elasticity, i.e. the more willing is Thomas to substitute housing for other goods.

If the elasticity of substitution equals σ^* , Thomas is *indifferent* between choices *a* and *b*, since both points lie on the respective *indifference curve*. However, if the elasticity of substitution is lower, say it equals σ_L , or higher, say it equals σ_H , then *b* will be worse than *a* and Thomas will not choose it. Hence, the elasticity of substitution is crucial in determining whether Thomas should move on economic grounds. Note that the elasticity of substitution is a measure for Thomas' preferences.

The utility function can be deduced if prices and the associated choices are observed and the elasticity of substitution is given. Thus, in MPSGE, a utility function is represented by benchmark (or observed) quantities, benchmark prices and the associated elasticity of substitution. Benchmark quantities determine an anchor point for the set of indifference curves. Benchmark prices fix the slope of the indifference curve at that point. The elasticity of substitution is a measure of the curvature of the indifference curve and specifies the utility function unambiguously.

4.49.1.1.2 Producer Supply Theory While consumers aim to maximize their utility subject to a budget, producers aim to reduce their cost of production given available technology. The activity of a firm is modeled as a *production function* that maps inputs into outputs. Inputs are primary factors like labor, capital, land, raw materials etc. and outputs are goods and services. Similarly to utility functions, in MPSGE, a production function is represented by reference quantities of reference prices of inputs and outputs, elasticities of substitution and elasticities of transformation.

Summarizing, the main principle for both, consumers and producers, is choice. Consumers choose quantities of goods given their preferences, prices and budgets. Producers choose quantities of primary factors and output levels given available technology. Available technology is modeled via elasticities of substitution between inputs and elasticities of transformation between outputs.

4.49.1.1.3 General Economic Equilibrium As mentioned above, MPSGE is a system for modeling general economic equilibria. General economic equilibrium analysis studies the working of an economic system as a whole. The basic assumption is that there are two types of agents in the economy: producers and consumers. Producers are assumed to operate with constant return to scale and to be perfectly competitive price-taking firms. Further, they are assumed to select factor inputs and output levels in order to maximize their profits given available technology. Consumers are assumed to maximize their welfare subject to budget constraints (incomes and endowments). An economy is in economic equilibrium if all consumers spend their given incomes such that they gain maximum satisfaction, all firms in each sector minimize their costs given available technology, and prices (for primary factors and commodities) and activity levels have adjusted such that all agents cannot do better by altering their behavior given the constraints they face. In equilibrium, all markets have cleared: in both, goods and factors markets, total demand equals total supply.

Mathematically, such an economy is modeled as a system of weak inequalities, where each inequality is associated with a non-negative variable denoting a price or a quantity. If a particular weak inequality holds as an equation, then the associated variable is strictly positive. If it holds as a strict inequality, then the associated variable equals zero. This is a mixed complementarity problem that can be formulated and solved with standard GAMS syntax. For details see section [Mixed Complementarity Problems \(MCPs\)](#). As we will demonstrate, MPSGE models can be translated to standard GAMS MCP models. However, the framework that MPSGE offers is much more user-friendly, since modelers do not have to input the complex equations manually.

4.49.1.2 Specifying an MPSGE Model

In this section we give an overview of the MPSGE model specification, a simple introductory example follows in the [next section](#). Like any standard GAMS program, a program with an embedded MPSGE model begins with set and parameter definitions that will later be used in the model. The MPSGE model is specified within an `$ontext` / `$offtext` block.

First, the name of the model must be defined:

```
$MODEL:mymodel
```

Here `$MODEL` is an [MPSGE keyword](#) and the model name `mymodel` is a GAMS [identifier](#).

In a GAMS program lines within `$on/offtext` are treated as a block comment. However, if the preprocessor encounters the MPSGE model definition statement, it will recognize that an MPSGE model specification follows and will process the code accordingly.

Note

Like GAMS, MPSGE is not case sensitive.

Secondly, the variables for an MPSGE model are declared. In every model, there are three classes *central variables*:

- **\$SECTORS**: variables for activity levels associated with constant returns to scale production sectors in the economy, which are non-negative,
- **\$COMMODITIES**: variables for commodity prices including all final goods, intermediate goods and primary factors of production, which are also non-negative, and
- **\$CONSUMERS**: variables for income levels, one for each “household” in the model, including any government entities.

In addition, models may include *auxiliary* variables (**\$AUXILIARY**) that are used to introduce endogenous tax instruments or endogenous endowment quantities to a model.

Note

Unlike GAMS models, variables in an MPSGE model must be declared over an explicit domain. Only variables that have been declared as one of the four MPSGE variable types may be used in the MPSGE model. Error messages are generated for variables which are declared but not referenced.

Thirdly, the parameters for functions are specified in a structured manner. The general syntax for all possible entries is given in section [Syntax for Production and Demand Functions](#) below. The MPSGE framework uses these specifications to automatically generate the respective market-clearing and income-balance equations. There are two types of functions:

- **\$PROD**: This block defines a production function, specifying inputs, outputs and elasticities of substitution and transformation. A production function must be given for each sector in the model. Note that most of the power and subtleties of the MPSGE framework center on the **\$PROD** tables.
- **\$DEMAND**: This block defines a demand function. This function represents preferences (using reference demands), initial factor endowments and elasticities of substitution. A demand function must be specified for each consumer in the model.

Finally, any auxiliary variable has an associated equilibrium condition that is defined by the user with conventional GAMS algebraic syntax and placed in a block called **\$CONSTRAINT**.

These four parts - model definition, variable declarations, function specifications and possibly side constraints for auxiliary variables - are the core of the MPSGE model specification. The model specification is followed by the dollar control option **\$offtext** and the following compiler directive:

```
$sysinclude mpsgeset mymodel
```

This compiler directive instructs MPSGE to compile the functions and generates an external file called **MYMODEL.GEN**. This external file is then loaded to the GAMS file with the following directive:

```
$include MYMODEL.GEN
```

Finally, a standard GAMS [solve statement](#) follows and the model will be handed for solution to one of the MCP solvers:

```
solve mymodel using mcp;
```

Observe that the appropriate GAMS model type is [MCP](#).

Most often the model is first evaluated at the benchmark point to test whether it is properly calibrated and everything works as expected. This is achieved by setting the option [iterlim](#) to zero. Then one or more counterfactuals are solved: first some parameter is modified using standard GAMS syntax, then the **\$include** statement is repeated and the model is solved again.

4.49.1.3 An Introductory Example: Two Goods and Two Factors in a Closed Economy

In the canonical 2x2 model, two final goods, X and Y , are produced with two primary factors, labor L and capital K , and there is a single representative agent (consumer) RA . The model is defined by technology, preferences and endowments. We can describe preferences by a utility function which provides an ordinal ranking of consumption levels for X and Y . We assume that both factors are in fixed supply, thus in equilibrium, factor endowments equal factor demands, and the supply of the two goods equal their demand.

The problem can be cast as consisting of three production activities, X , Y and U , and five markets X , Y , U , K and L . The initial data for the model are given by the following matrix.

Markets	Production Sectors			Consumers	Row Sums
	X	Y	U	RA	
PX	100		-100		0
PY		50	-50		0
PU			150	-150	0
PK	-50	-20		70	0
PL	-50	-30		80	0
Column Sums	0	0	0	0	

The data describes a representative equilibrium. Rows correspond to markets, where PX , PY , PU , PK and PL are the prices for the commodity X , the commodity Y , the utility U , and capital and labor respectively. Positive entries denote the value of commodity flows *into* the economy (sales or factor supplies) and negative entries represent the value of commodity flows *out* of the economy (factor demands and good demands). Observe that the sum of a row will equal zero if the market clears, i.e. the total amount of commodity that flows into the economy equals the total amount of this commodity that flows out of the economy. The matrix is called *balanced* if all rows and columns sum to zero.

Note that the layout of the matrix ensures that a complete list of the transactions associated with an activity is given in each production column. The sum of a production sector column is zero if the value of the outputs equals the costs of the inputs. A consumer column is balanced if the sum of primary factor sales equals the value of final demands. Hence columns that sum to zero indicate zero profits. This type of matrix is related to the concept of a *social accounting matrix* (or short: *SAM*).

The problem can be modeled with GAMS MPSGE as follows:

```
Parameter    endow      index of labour endowment      / 1.0 /;
```

```
*          MPSGE model declaration follows
```

```
$ontext
```

```
$MODEL:twobytwo
```

```
$SECTORS:
```

```
  X  ! Activity level for sector X -- benchmark=1
  Y  ! Activity level for sector Y -- benchmark=1
  U  ! Activity level for sector U -- benchmark=1
```

```
$COMMODITIES:
```

```
  PX ! Relative price index for commodity X -- benchmark=1
  PY ! Relative price index for commodity Y -- benchmark=1
  PU ! Relative price index for commodity U -- benchmark=1
```

```

    PL ! Relative price index for labor -- benchmark=1
    PK ! Relative price index for capital -- benchmark=1

$CONSUMERS:
    RA ! Income level for representative agent -- benchmark=150;

$PROD:X s:1
    O:PX Q:100
    I:PL Q: 50 ! Variable LX in the algebraic model
    I:PK Q: 50 ! Variable KX in the algebraic model

$PROD:Y s:1
    O:PY Q: 50
    I:PL Q: 20 ! Variable LY in the algebraic model
    I:PK Q: 30 ! Variable KY in the algebraic model

$PROD:U s:1
    O:PU Q:150
    I:PX Q:100 ! Variable DX in the algebraic model
    I:PY Q: 50 ! Variable DY in the algebraic model

$DEMAND:RA
    D:PU
    E:PL Q: (70*endow)
    E:PK Q: 80

$offtext

* Compiler directive instructing MPSGE to compile the functions

$sysinclude mpsgeset twobytwo

* Benchmark replication

twobytwo.iterlim = 0;
$include TWOBYTWO.GEN
solve twobytwo using mcp;
abort$(abs(twobytwo.objval) gt 1e-7) "*** twobytwo does not calibrate ! ***";
twobytwo.iterlim = 1000;

* Counterfactual : 10% increase in labor endowment

endow = 1.1;

* Solve the model with the default normalization of prices which
* fixes the income level of the representative agent. The RA
* income level at the initial prices equals 80 + 1.1*70 = 157.

$include TWOBYTWO.GEN
solve twobytwo using mcp;

```

Note that an algebraic version of this model using standard GAMS syntax is given in the [Appendix](#).

After the model statement where the model is named, variables are declared in each of the three central variable classes. Unlike conventional GAMS syntax, in MPSGE, trailing comments in variable declarations (starting with the symbol !) are interpreted as variable descriptors that will appear in the listing file.

Then three production blocks \$PROD - one for each sector - follow. Output parameters are specified in the line starting with the label O and input parameters are given in the line starting with the label I,

the respective quantities are listed in the field `Q`. Note that the first input in the production block for sector `X` represents labor demand in sector `X` and the second input represents capital demand in sector `X`. Similarly, the inputs in the production block for sector `Y` represent labor and capital demand for sector `Y`. In the production block for sector `U`, the inputs represent demand for `X` and `Y` in sector `U`. In the field `s`: next to the name of the sector the elasticity of substitution between the inputs is specified.

A demand block `$DEMAND` for the consumer `RA` completes the model specification. Demand parameters are specified in the line starting with the label `D` and endowment parameters are given in the line starting with the label `E`. Note that all possible entries for production and demand blocks are discussed in section [Syntax for Production and Demand Functions](#). Observe that there is no algebraic formulation of equations, only parameter specifications. Given this input, the MPGSGE framework generates the respective equations automatically.

Note that it is not necessary to fix a numeraire. If a numeraire is not specified, the normalization of prices is arbitrary. For example, in the model above, `RA` is used as a numeraire and the following remark appears in the listing file:

```
Default price normalization using income for RA
```

Note that the version of this model in the [Appendix](#) includes two additional counterfactual scenarios, where first sector `X` is used as numeraire commodity and then the wage rate `PL` is fixed as numeraire. In the [Appendix](#), there are also two alternative versions of the model above: a model in [standard GAMS syntax](#) where the equations that are automatically generated by the MPSGE framework are given explicitly, and an [MPSGE model](#) that uses vector notation instead of scalars.

4.49.1.4 Modeling Intermediate Demand and Joint Production

In this section we extend the two by two model above in the following three ways:

1. We distinguish between production sectors and produced goods.
2. Each sector produces both goods, so we have *joint production*.
3. In addition to primary factors like labor and capital, goods enter the production process as inputs. Thus we have *intermediate demand*.

The full MPSGE model and MCP and NLP versions of the model are given in the [Appendix](#). Here we reproduce and discuss only selected code snippets. The main difference to the simple model above is the specification of the production block:

```
$PROD:X(j)   s:1   t:1
      O:P(i)   Q:make0(i,j)   ! S(i,j) in the MCP and NLP models
      I:P(i)   Q:use0(i,j)    ! D(i,j) in the MCP and NLP models
      I:PF(f)  Q:fd0(f,j)     ! FD(f,j) in the MCP and NLP models
```

Note that the supply is specified in the output line, the intermediate demand is given in the first input line and the factor demand is listed in the second input line. Thus each sector `j` produces the goods `i` using the intermediate goods `i` and the primary factors `f`. Consider the fully spelled-out production block for sector `s1`:

```
$PROD:X("s1")   s:1   t:1
      O:P("g1")   Q:6.0
      O:P("g2")   Q:2.0
      I:P("g1")   Q:4.0
      I:P("g2")   Q:2.0
      I:PF("labor") Q:1.0
      I:PF("capital") Q:1.0
```

At benchmark, sector `s1` produces 6 units of good `g1` and 2 units of good `g2`. The input for this output is 4 units of the good `g1`, 2 units of the good `g2` and labor (one unit) and capital (one unit).

Note

Double quotes have to be used if a singleton set element is referenced in an MPSGE model. Single quotes are not recognized.

Observe that the technology used to combine these four production factors is based on a Cobb-Douglas production function, i.e. the elasticity of substitution equals 1, as indicated by the value in field **s**. In addition, the curvature of the production possibility frontier (the constant elasticity of transformation function) is given in field **t**.

4.49.1.5 Modeling a Small Open Economy

An open economy is one in which goods are traded on international markets, typically at fixed international prices, i.e. there are imports and exports. One class of models for small open economies are known as "123 models" [64]. In the original 123 model, there was one small country, two producing sectors and three goods (one domestic good, one import good and one export good). The 123 model we present and discuss in this section has exogenously given world prices for imports and exports, taxes, labor-leisure choice, classical unemployment and joint production. The programming language keeps track of tax revenue flows, equations which are otherwise tedious to program. The model is a tiny version of the open economy GTAP model [149]. It follows the canonical microeconomic optimization framework: (i) consumers maximize welfare subject to a budget constraint with fixed levels of investment and public expenditure, and (ii) producers combine intermediate inputs and primary factors at least cost for given technology.

Note that the full MPSGE model **mge123** and an algebraic version are given in the [Appendix](#). In addition, we introduce and discuss a version of the model that includes [nesting](#). Note further, that the data for the model and its variants are included in a [separate GAMS file](#). Observe that the input-output matrix in the data file provides data on value flows for primary production factors, intermediate goods and final consumption products. In the following, we comment on selected code snippets and thereby discuss the most important features of the model.

Consider the production block for the entire production of the small economy:

```
$PROD:Y  t:etadx s:esubkl
          O:PD    Q:d0    P:1                      ! YD
          O:PX    Q:x0    P:px0  A:GOVT  T:tx          ! YX
          I:RK    Q:kd0    P:rr0  A:GOVT  T:tk          ! KD
          I:PL    Q:ly0    P:pl0  A:GOVT  T:t1  N:TAU_TL ! LY
```

Note that the first output line represents production for the domestic market, which is denoted by the variable **YD** in the algebraic version of the model. The reference price at benchmark is given in the new field **P**.

Note

The default value for both **P** and **Q** fields is 1.0

The second output line represents production for the export market (variable **YX** in the algebraic version). Observe that taxes are specified in the two new fields **A** and **T**: the tax recipient is specified in field **A** and the tax rate is listed in field **T**. Note that the tax recipient must reference a **\$CONSUMER** variable and the tax rate **tx** (tax rate on exports) is given *exogenously*.

Attention

In MPSGE, the way exogenous taxes are computed depends on whether they are imposed on outputs or inputs. Taxes on *outputs* are specified on a *gross* basis. Hence, if a tax on outputs has proportional rate t , the producer price will be $p(1 - t)$, where p is the market price. However, taxes on *inputs* are specified on a *net* basis. Hence, if a tax on inputs has ad valorem rate t , the user cost will be $p(1 + t)$, where p is the market price.

The first input line represents capital demand (variable KD in the algebraic version). The model includes investment by the private (domestic) households, thus the variable RK denotes a rental price index. Observe that capital is taxed exogenously at the capital tax rate tk.

The second input line represents labor demand (variable LY in the algebraic version). In addition to an exogenous labor tax t1, an *endogenous* tax is imposed on this input. The endogenous tax rate is determined by the auxiliary variable TAU_TL, which is the entry in the field N at the end of the line. Note that an equation associated with the auxiliary variable is specified in the following block:

```
$CONSTRAINT:TAU_TL
      GOVT =e= PA * g0;
```

Note

When an auxiliary variable is fixed no constraint is required. When the lower bound of the auxiliary variable is less than the upper bound, a constraint is required.

Note further, that the variable TAU_TL is a wage replacement tax and at benchmark, it is fixed at zero. It is positive in two of the four counterfactual scenarios.

Domestic demand is modeled using the Armington assumption: consumers demand one single good which is an aggregation of *composite goods* consisting of the goods produced domestically and the imported versions, where imports and domestic goods in the same sector are imperfect substitutes. The aggregated composite good is given by a constant elasticity of substitution aggregation function of the domestic goods and the imported goods with elasticity of substitution **sigmadm**. In our model, **sigmadm** equals 4 (domestic versus imported goods). The production of the Armington good is specified in the following block:

```
$PROD:A  s:sigmadm
      O:PA    Q:a0    A:GOVT  t:ta
      I:PD    Q:d0
      I:PM    Q:m0    p:pm0 A:GOVT t:tm  ! DA
                                     ! MA
```

Note that both inputs are intermediate goods. The first input line represents domestic absorption (variable DA in the algebraic version of the model) and the second input line represents imports (variable MA in the algebraic version). Imports are taxed with the import tariff rate tm and the composite good is taxed with the excise and sales tax rate ta. Both taxes are exogenous.

In addition, the model contains production blocks for imports and exports. Foreign exchange (denoted by the MPSGE variable PFX) is used in these two production blocks. It is the input in the production block for imports and the output in the production block for exports.

The two consumers in the model are the government (MPSGE variable GOVT) and aggregated private households (MPSGE variable HH). The demand block for the government agent is as follows:

```

$DEMAND:GOVT
    E:PFX    Q:bopdef
    E:PA     Q:dtax
    E:PA     Q:g0          R:TAU_LS
    D:PA

```

Note that the first endowment line represents the balance of payment in the current account (denoted by the \$COMMODITIES variable PFX). In our model, exports exceed imports resulting in the deficit `bopdef`. If imports are larger than exports there will be a surplus. The other two endowment lines represent taxes that are paid by the households: a direct tax `dtax` and a lumpsum labor replacement tax that is specified as an auxiliary variable and determined by the respective complementarity equation. In this model the labor replacement tax is either a lumpsum tax (TAU_LS) or it is levied on labor at a tax rate of TAU_TL (see above). Note that the direct tax and the lumpsum tax feature in the demand block for HH as *negative* endowments. Negative endowments represent payments to be made. The demand block for HH follows:

```

$DEMAND:HH  s:sigma
    E:PA     Q:(-g0)          R:TAU_LS
    E:PA     Q:(-dtax)
    E:RK     Q:kd0
    E:PA     Q:(-i0)
    E:PL     Q:(1y0+10)      ! Labor endowment = 1y0+10 - UR * (1y0+10)
    E:PL     Q:(-(1y0+10))   R:UR
    D:PA     Q:c0
    D:PL     Q:l0

```

Households demand two goods: the Armington composite good PA (first demand line) and leisure (second demand line). Note that the first two endowment lines represent taxes as discussed above. The third and fourth endowment line relate to capital: the third line represents the income generated by capital investment and the fourth line represents capital investments. The last two endowment lines refer to labor. Labor endowment for the aggregated households equals the sum of labor and leisure minus the percentage of unemployment. Note that at benchmark, the unemployment rate `UG` is fixed at zero, other scenarios are explored in the counterfactuals.

In model `mge123`, the rate of substitution for domestic and imported goods that constitute the Armington good PA is fixed at `sigmadm = 4`. Suppose that we want more control over substitution possibilities. For example, we may wish to model a substitution rate in final demand that is different than for other uses of the Armington good. MPSGE facilitates modeling this additional degree of freedom through *nesting*. Consider the following demand block for HH from model `mgenested`, a variant of model `mge123`:

```

$DEMAND:HH  s:sigma    c:sigmac
    E:PA     Q:(-g0)          R:TAU_LS
    E:PA     Q:(-dtax)
    E:RK     Q:kd0
    E:PA     Q:(-i0)
    E:PL     Q:(1y0+10)      ! Labor endowment = 1y0+10 - UR * (1y0+10)
    E:PL     Q:(-(1y0+10))   R:UR
    D:PD     Q:cd0    c:
    D:PM     Q:cm0    c:
    D:PL     Q:l0

```

Note that in this formulation the endowment lines are unchanged and we have three demand lines. The first two demand lines have an additional field (`c:`). This tag indicates that these two goods are part of a nest: they are combined to an intermediate good called C. The rate of substitution for the goods in the nest is given in the first line of the demand block: `c:sigmac`. Observe that except for the substitution

rate, **C** equals **PA**. The structure of the final demand can be presented graphically using the following nesting diagram:

Figure 4.4 Structure of nested demand for **HH**

The nested utility function, expressed as a *unit function* is:

$$U = \left[\theta \left(\frac{\ell}{\bar{\ell}} \right)^{1-1/\sigma} + (1-\theta) \left(\alpha \left(\frac{D}{\bar{D}} \right)^{1-1/\sigma_C} + (1-\alpha) \left(\frac{M}{\bar{M}} \right)^{1-1/\sigma_C} \right)^{\frac{1-1/\sigma}{1-1/\sigma_C}} \right]^{1/1-1/\sigma}$$

in which θ is the budget share of leisure (ℓ) in aggregate expenditure, and α is the budget share of domestic goods (D) in commodity expenditure, both evaluated at the benchmark point:

$$\theta = \frac{\bar{\ell}}{\bar{\ell} + \bar{D} + \bar{M}}$$

and

$$\alpha = \frac{\bar{D}}{\bar{D} + \bar{M}}$$

The demand for leisure is a function of extended income (**HH**):

$$\ell = \bar{\ell} \left(\frac{p_U}{p_\ell} \right)^\sigma \frac{HH}{p_U (\bar{\ell} + \bar{D} + \bar{M})}$$

The demand for domestic and imported goods is a function of both the top-level elasticity of substitution, σ , as well as the elasticity of substitution between consumption goods, σ_C :

$$D = \bar{D} \left(\frac{p_U}{p_C} \right)^\sigma \left(\frac{p_C}{p_D} \right)^{\sigma_C} \frac{HH}{p_U (\bar{\ell} + \bar{D} + \bar{M})}$$

and

$$M = \bar{M} \left(\frac{p_U}{p_C} \right)^\sigma \left(\frac{p_C}{p_M} \right)^{\sigma_C} \frac{HH}{p_H (\bar{\ell} + \bar{D} + \bar{M})}$$

The graph illustrates the two-level nesting structure. Domestic goods and imports are combined in the second-level nest with an elasticity of substitution of **sigmac**. Here we use the identifier **C**.

Note

The name space of nesting assignments is segmented from that of sets, parameters and variables in the GAMS code. Two set identifiers are predefined: `s:` and `t:`. All other identifiers are accepted provided they have four or fewer characters.

The full model `mgenested` is given in the [Appendix](#). Observe that as the substitution rate of the Armington good in final demand has changed, some parameters are modified at the beginning of the program in order to recalibrate the model.

A tariff reform is similar to a tax reform, it has a major influence on the structure of the budget of a government. Suppose we wish to keep government expenditure constant and experiment with different scenarios that represent different combinations of tax instruments. For example, at benchmark, in our model the unemployment rate `UR` and the endogenous wage tax `TAU.TL` are fixed at zero. Four alternative closures are explored in the counterfactuals. They depend on revenue replacement (lumpsum versus wage tax) and labor market (flexible versus fixed wages). An overview of the outcomes are given in the following table:

----- 1914 PARAMETER report Tariff Remove with Revenue Replacement (% impact)

	Lump Sum		Wage Tax	
	Flexible	Rigid Wage	Flexible	Rigid Wage
PFX	4.6	4.6	13.0	9.4
PD	-2.1	-2.1	5.9	2.6
RK	0.6	0.6	7.9	-1.6
PA	-4.5	-4.5	3.3	2.22045E-14
GOVT	3299.9	3299.9	3574.4	3458.3
HH	40184.6	40184.6	42403.1	38219.6
PX	4.6	4.6	13.0	9.4
W	0.4	0.4	0.3	-7.5
Y	0.3	0.3	-0.5	-6.3
A	0.7	0.7	-4.15640E-2	-5.3
M	13.7	13.7	13.0	7.5
X	18.7	18.7	17.6	10.2
YD	-8.8	-8.8	-9.5	-14.6
YX	18.7	18.7	17.6	10.2

DA	-8.8	-8.8	-9.5	-14.6
MA	13.7	13.7	13.0	7.5
C	1.0	1.0	-5.89421E-2	-7.5
LD	-0.9	-0.9	1.2	-7.5
PM	4.6	4.6	13.0	9.4
TAU_LS	38.1	38.1		
TAU_TL			9.1	11.9
UR				10.0

Note that the classical unemployment part in this model provides a good way to motivate the usefulness of the modeling framework. We easily produce a model which illustrates the importance of the labor market formulation. When the real wage is downward rigid, replacement of tariffs with wage taxes reduces welfare (denoted by `W`) by 7.9%, output by 6.6% and employment by 10%. If the wage is flexible, replacement of tariffs by wage taxes leads to a 0.1% decrease in welfare.

4.49.1.6 MPSGE Keywords and Syntax

In the presentation of the general syntax in this section, we use the usual GAMS syntax symbols: `[ ]` (the enclosed construct is optional), `{ }` (the enclosed construct may be repeated zero or more times) and `|` (exclusive OR). EOL means "end-of-line" and `num.expr` denotes a number or [GAMS numerical expression](#) that may include a [dollar condition](#) for exception handling.

4.49.1.6.1 MPSGE Keywords MPSGE provides nine keywords that are used to specify an MPSGE model. They are given in [Table 1](#). Note that these keywords are *not* [GAMS reserved words](#), i.e. they are not keywords in the GAMS code apart from the MPSGE model specification.

MPSGE Keyword and Syntax	Description
<code>\$MODEL:model_name</code>	This keyword is used to assign the identifier <code>model_name</code> to the model. <code>Model_name</code> must be a valid file name, since it is used to form <code>model_name.GEN</code> . This must be the first statement within the <code>\$ontext - \$offtext</code> block containing the MPSGE code; all lines in an <code>\$ontext - \$offtext</code> block before this keyword are treated as comments.
<code>\$SECTORS:</code> <code>sect1 ! Description1</code> <code>sect2 ! Description2</code> ...	This keyword is used to declare one or more variables for sectors that are used in the model.
<code>\$COMMODITIES:</code> <code>com1 ! Description1</code> <code>com2 ! Description2</code> ...	This keyword is used to declare one or more variables for commodities that are used in the model.
<code>\$CONSUMERS:</code> <code>cons1 ! Description1</code> <code>cons2 ! Description2</code> ...	This keyword is used to declare one or more variables for consumers that are used in the model.
<code>\$AUXILIARY:</code> <code>aux1 ! Description1</code> <code>aux2 ! Description2</code> ...	This keyword is used to declare one or more auxiliary variables. It is only used in models with side constraints and endogenous taxes or rationed endowments.
<code>\$PROD:sector</code>	This keyword is used to specify a production function. A production function must be specified for each sector in the model. Note that <code>sector</code> must have been previously declared with a <code>\$SECTORS</code> statement.
<code>\$DEMAND:consumer</code>	This keyword is used to define a demand function. A demand function must be specified for each consumer in the model. Note that <code>consumer</code> must have been previously declared with a <code>\$CONSUMERS</code> statement.
<code>\$CONSTRAINT:auxiliary</code>	This keyword is used to specify a side constraint to be associated with the auxiliary variable <code>auxiliary</code> . Note that <code>auxiliary</code> must have been previously declared with an <code>\$AUXILIARY</code> statement.
<code>\$REPORT:</code>	This keyword identifies the set of additional variables to be calculated. These variables are used for reports and include outputs and inputs by sector, and demands and welfare by individual consumers. The variables declared in <code>\$REPORT</code> blocks may not be used in model equations. Note that we did not discuss report blocks in this chapter. For details see [168] .

Table 1: MPSGE Keywords

4.49.1.6.2 Syntax for Production and Demand Functions In addition to the keywords above, MPSGE provides a fixed structure for specifying production and demand functions. This structure has a tabular format with pre-specified fields (or labels). The names of most fields are single letters that are reserved words in MPSGE. The exception are nest identifiers: they are arbitrary names with up to four characters.

The syntax for the definition of a production function is as follows.

```

$PROD:sector      [s:num_expr]    [t:num_expr]    [a:num_expr {b:num_expr}]
0:commodity1      [Q:num_expr]    [P:num_expr]    [A:consumer]    [T:num_expr {T:num_expr}] [N:auxiliary]
I:commodity2      [Q:num_expr]    [P:num_expr]    [A:consumer]    [T:num_expr {T:num_expr}] [N:auxiliary]

```

Note that the numerical expression `num_expr` may be a parameter or a value.

Each production function block starts with the MPSGE keyword `$PROD` and the respective `sector`. Note that the variable `sector` must have been previously defined in the `$SECTORS` block. The labels that follow are optional. They include the following:

- **s**: Top level elasticity of substitution between inputs. The default value is zero.
- **t**: Elasticity of transformation between outputs in production. Can be zero, but not infinity.
- **a**;**b**;**:****:****:** Elasticities of substitution in individual input nests. Here **a** and **b** are nest identifiers.

Each production block has at least one output line **O** and one input line **I**. The value in the fields **O** and **I** is a `commodity` that has been previously declared in the `$COMMODITIES` block. Note that only this first field is mandatory, all other entries are optional and depend on the model. The valid labels for both lines include the following:

- **Q**: Reference quantity. Default value is 1. When specified, it must be the second entry.
- **P**: Reference price. Default value is 1.
- **A**: Tax revenue agent, the entry must be a `consumer` that has been previously defined in the `$CONSUMERS` block. This field must appear *before* the corresponding **T** or **N** field.
- **T**: Tax rate of the *exogenous* tax rate. Note that more than one tax rate may be listed in one line.
- **N**: *Endogenous* tax, the entry is an `auxiliary` variable that has been previously defined in the `$AUXILIARY` block.
- **M**: Endogenous tax multiplier. The ad valorem tax rate is the product of the value of the endogenous tax and this multiplier. Note that if the **M** field is omitted in a line with an **N** field, **M:1** will be assumed. Observe that the **M** field cannot be included in the absence of an **N** field.
- **a**;**b**;**:****:****:** Nesting assignments. Only one such label may appear per line.

The syntax for the specification of a demand function is as follows.

```

$DEMAND:consumer  [s:num_expr]    [a:num_expr {b:num_expr}]
D:commodity1      [Q:num_expr]    [P:num_expr]                    [a: | b:]
E:commodity2      [Q:num_expr]    [R:auxiliary]

```

Each demand function block starts with the MPSGE keyword `$DEMAND` and the respective `consumer`. Note that the variable `consumer` must have been previously declared in the `$CONSUMERS` block. The labels that follow are optional. They include the following:

- **s**: Top level elasticity of substitution between demands.
- **a**;**b**;**:****:****:** Elasticities of substitution in individual demand nests.

Each demand block has at least one demand line **D** and it may have one or more endowment lines **E**. The value in the fields **D** and **E** is a `commodity` that has been previously declared in the `$COMMODITIES` block. Note that only this first field is mandatory, all other entries are optional and depend on the model. The valid labels in a **D** line include the following:

- **Q**: Reference quantity. Default value is 1. When specified, it must be the second entry.
- **P**: Reference price. Default value is 1.
- **a**;**b**;**:**... Nesting assignments. Only one such label may appear per line.

The valid labels in an **E** line include the following:

- **Q**: Reference quantity. Default value is 1. When specified, it must be the second entry.
- **R**: Rationing instrument, the entry is an **auxiliary** variable that has been previously defined in the **\$AUXILIARY** block.

Auxiliary constraints in MPSGE models conform to standard [GAMS equation syntax](#). They may refer to any of the four classes of variables, **\$SECTORS**, **\$COMMODITIES**, **\$CONSUMERS** and **\$AUXILIARY**, but they may not reference variables names declared within a **\$REPORT** block. Complementarity conditions apply to upper and lower bounds on auxiliary variables and the associated constraints. For this reason, the orientation of the equation is important. When an auxiliary variable is designated **POSITIVE** (the default), the auxiliary constraint should be expressed as an equation of the type **=g=**. If an auxiliary variable is designated **FREE**, the associated constraint must be expressed as an equality (**=e=**).

4.49.1.6.3 Domain Restrictions on Variable Declarations Domain restrictions on variable declarations are a crucial difference between models formulated in GAMS and those formulated in MPSGE. In GAMS, variables are defined over a domain, but the explicit domain used in the model is determined by CMEX at the point when the model is generated. In an MPSGE model, users are required to declare the explicit domain for every variable. If they include variables which are not referenced in the model, they will get a "No source" or "No sink" error message. If a variable is referenced which is not declared, an error message will be generated by the MPSGE function evaluator.

Consider the following example of a sector declaration in MPSGE:

```
$SECTORS:
  Y(i)$y0(i)
  M(i)$m0(i)
...
```

The corresponding production blocks need to have the corresponding exception operators:

```
$PROD:Y(i)$y0(i)
...
$PROD:M(i)$m0(i)
...
```

For more information on exception handling in GAMS, see chapter [Conditional Expressions, Assignments and Equations](#).

4.49.1.6.4 The Nest Labor Operator and the Spanning Operator The nest labor operator (`.tl`) is used to create a set of nests. The following example serves as illustration and is self-explanatory:

```
$PROD:Y      s:0.5    m:0    i.tl(m):esubdm(i)    va:1
O:PY        Q:y0
I:PD(i)     Q:d0(i)      i.tl:
I:PM(i)     Q:m0(i)      i.tl:
I:PK        Q:k0                      va:
I:PL        Q:l0                      va:
```

The spanning operator (`#`) is a way to provide multiple inputs of one commodity. For example, a commodity with price `PM` is a wholesale/retail trade margin. The benchmark value of margins on commodity `i` is `md0(i)`, and the net of margin (wholesale) value of commodity `i` sales is `d0(i)`. If goods trade off in a Cobb-Douglas nest at the gross of margin price, we can represent this in an MPSGE model as:

```
$PROD:A      s:1      i.tl:0
O:PA        Q:a0
I:P(i)      Q:d0(i)    i.tl:
I:PM#(i)    Q:md0(i)  i.tl:
```

4.49.1.7 MPSGE-Specific Output

The output in the listing file of an MPSGE model has some distinctive features. Note that the MPSGE model specification is reproduced in the [echo print](#). After the directive `$offtext`, the echo print is interrupted and a [symbol reference map](#) is inserted. In this map, both, the identifiers defined using standard GAMS syntax and MPSGE variables are listed. In addition to the [standard GAMS data types](#), the following MPSGE shorthand symbols may appear in this listing:

Shorthand Symbol	MPSGE Data Type
ACTIV	sector variable
AUXIL	auxiliary variable
CONSU	consumer variable
PRICE	commodity variable

Table 2: Shorthand Symbols for MPSGE Data Types

For example, the symbol reference map for the first simple model in vector notation reads as follows:

Symbol Listing

Symbol	Type	References							
=====	=====	=====							
CONS	PARAM	19	23						
DEMAND	PARAM	20							
ENDOW	PARAM	24							
F	SET	9	16	16	24	24			
FACTOR	PARAM	16							
I	SET	3	14	15	15	16	20	20	
PC	PRICE	8	15	20					
PF	PRICE	9	16	24					
PU	PRICE	7	19	23					

RA	CONSU	12	22
SUPPLY	PARAM	15	
U	ACTIV	4	18
Y	ACTIV	3	14

Note that if the normalization was done automatically, a comment will appear after the [solve summary](#) detailing which variable was used as a numeraire. For example,

```
Default price normalization using income for RA
```

Observe that the lower, level, upper and marginal values of the MPSGE variables are given in the [solution listing](#) like for any other GAMS variable. For more information on standard GAMS output, see chapter [GAMS Output](#).

4.49.2 MPSGE Models in GAMS

MPSGE is a *mathematical programming system for general equilibrium analysis* which operates as a subsystem within GAMS. MPSGE is essentially a library of function and Jacobian evaluation routines which facilitates the formulation and analysis of AGE models. MPSGE simplifies the modeling process and makes AGE modeling accessible to any economist who is interested in the application of these models. In addition to solving specific modeling problems, the system serves a didactic role as a structured framework in which to think about general equilibrium systems.

MPSGE requires the GAMS/BASE Module including the [MILES](#) MCP solver. Optionally it can use the [PATH 4.7](#) MCP solver.

4.49.2.1 Introduction

This paper introduces a programming language for economic equilibrium modeling. The paper presents the motivation for the system, the programming syntax, and three small scale examples. A library of larger models are provided with the program. The purpose of the paper is to provide a concise introduction to the modeling environment.

MPSGE is a modeling language specially designed for solving Arrow-Debreu economic equilibrium models. (See Rutherford (1987, 1989).) The name stands for "mathematical programming system for general equilibrium". The idea of the *MPSGE* program is to provide a transparent and relatively painless way to write down and analyze complicated systems of nonlinear inequalities. The language is based on nested constant elasticity of substitution utility functions and production functions. The data requirements for a model include share and elasticity parameters for all the consumers and production sectors included in the model. These may or may not be calibrated from a consistent benchmark equilibrium dataset.

GAMS, the "Generalized Algebraic Modeling System", is a modeling language which was originally developed for linear, nonlinear and integer programming. This language was developed over 15 years ago by Alex Meeraus when he was working at the World Bank. (See Brooke, Kendrick and Meeraus (1988).) Since that time, *GAMS* has been widely applied for large-scale economic and operations research modeling projects.

MPSGE and *GAMS* embody different philosophies in their designs. *MPSGE* is appropriate for a specific class of nonlinear equations, while *GAMS* is capable of representing any system of algebraic equations. While *GAMS* is applicable in several disciplines, *MPSGE* is only applicable in the analysis of economic models within a particular domain. The expert knowledge embodied in *MPSGE* is of particular use to

economists who are interested in the insights provided by formal models but who are unable to devote many hours to programming. *MPSGE* provides a structured framework for novice modellers. When used by experts, *MPSGE* reduces the setup cost of producing an operational model and the cost of testing alternative specifications.

Prior to the connection with *GAMS*, the "achilles heel" of *MPSGE* had been the process by which input data was translated into the tabular format of the *MPSGE* input file. For small models, this translation was not difficult. Given a calibrated "benchmark equilibrium dataset", a couple of hours with a word processor is usually enough time to generate and investigate a moderately large model. If, however, a model involves several classes of sectors and agents, a wide range of tax instruments and large tables of input data, the word-processor approach is impossible. When there are many numbers, there are many opportunities for oversights and typographical errors.

In contrast, the *GAMS* modeling language is designed for managing large datasets. The use of sets and detached-coefficient matrix notation makes the *GAMS* environment very nice for both developing balanced benchmark datasets and for writing solution reports. For large complicated models, a shortcoming of the *GAMS* modeling environment lies in the specification of the nonlinear equations. Economic equilibrium models, particularly those based on complicated functions such as nested CES, are easier to understand at an abstract level than they are to specify in detail, and the translation of a model from input data into algebraic relations can be a tedious and error-prone undertaking.

The interface between *GAMS* and *MPSGE* combines the strengths of both programs. The system uses *GAMS* as the "front end" and "back end" to *MPSGE* facilitating data handling and report writing. The language employs an extended *MPSGE* syntax based on *GAMS* sets, so that model specification is very concise. In addition, the system includes two large-scale solvers, MILES (Rutherford (1993)) and PATH (Ferris and Dirkse (1993)), which may be used interchangeably. The availability of two algorithms greatly enhances robustness and reliability.

The remainder of this paper is organized as follows. Section 2 introduces *MPSGE* input syntax and the *GAMS* interface using a small two-sector model of taxation. Section 3 extends the 2x2 model to illustrate how the software is used to perform equal-yield (differential) tax policy analysis and to analyze tax reform in a model with endogenous taxation. Section 4 provides a brief summary and conclusion. The paper introduces language features largely through example. Details on language syntax and program structure are provided in two appendices. Appendix A provides a complete statement of *MPSGE* syntax and a summary of differences with the original (1989) language. Appendix B provides an overview of the modeling environment and the structure of *GAMS* input files which employ *MPSGE*.

Before proceeding, both to placate impatient readers and to provide some hands-on experience for novices, I recommend that readers install the *GAMS* system, then retrieve and process the library file *THREEMGE* which contains three *MPSGE* models (*HARBERGER*, *SHOVEN* and *SAMUELSON*). Two commands to retrieve and run these models:

```
gamslib threemge
gams threemge
```

After having processed this file, print the listing files (*THREEMGE.LST*) for reference.

4.49.2.2 A Mathematical Introduction

Mathiesen (1985) demonstrated that an Arrow-Debreu general economic equilibrium model could be formulated and efficiently solved as a complementarity problem. Mathiesen's formulation may be posed in terms of three sets of "central variables":

p = a non-negative n -vector of commodity prices including all final goods, intermediate goods and primary factors of production;

y = a non-negative m -vector of activity levels for constant returns to scale production sectors in the economy; and

M = an h -vector of income levels, one for each "household" in the model, including any government entities.

An equilibrium in these variables satisfies a system of three classes of nonlinear inequalities.

Zero Profit

The first class of constraint requires that in equilibrium no producer earns an "excess" profit, i.e. the value of inputs per unit activity must be equal to or greater than the value of outputs. This can be written in compact form as:

$$-\Pi_j(p) = C_j(p) - R_j(p) \geq 0 \quad \forall j$$

where $\Pi_j(p)$ is the unit profit function, the difference between unit revenue and unit cost, defined as:

$$C_j(p) = \min\left\{\sum_i p_i x_i \mid f_j(x) = 1\right\}$$

and

$$R_j(p) = \max\left\{\sum_i p_i y_i \mid g_j(y) = 1\right\}$$

where f and g are the associated production functions characterizing feasible input and output. For example, if we have:

$$f(x) = \phi \prod_i x_i^{\alpha_i} \quad \sum_i \alpha_i = 1, \quad \alpha_i \geq 0$$

and

$$g(y) = \psi \max_i \frac{y_i}{\beta_i} \quad \beta_i \geq 0$$

then the dual functions will be:

$$C(p) = \frac{1}{\phi} \prod_i \left(\frac{p_i}{\alpha_i}\right)^{\alpha_i}$$

and

$$R(p) = \sum_i \beta_i p_i$$

Market Clearance

The second class of equilibrium conditions is that at equilibrium prices and activity levels, the supply of any commodity must balance or exceed excess demand by consumers. We can express these conditions as:

$$\sum_j y_j \frac{\partial \Pi_j(p)}{\partial p_i} + \sum_h \omega_{ih} \geq \sum_h d_{ih}(p, M_h)$$

in which the first sum, by Shepard's lemma, represents the net supply of good i by the constant-returns to scale production sectors, the second sum represents the aggregate initial endowment of good i by households, and the sum on the right-hand-side represents aggregate final demand for good i by households, given market prices p and household income levels M . Final demand are derived from budget-constrained utility maximization:

$$d_{ih}(p, M_h) = \operatorname{argmax}\{U_h(x) \mid \sum_i p_i x_i = M_h\}$$

in which U_h is the utility function for household h .

Income Balance

The third condition is that at an equilibrium, the value of each agent's income must equal the value of factor endowments:

$$M_h = \sum_i p_i \omega_{ih}$$

We always work with utility functions which exhibit non-satiation, so Walras' law will always hold:

$$\sum_i p_i d_{ih} = M_h = \sum_i p_i \omega_{ih}$$

Aggregating market clearance conditions using equilibrium prices and the zero profit conditions using equilibrium activity levels, it then follows that:

$$\sum_j y_j \Pi_j(p) = 0$$

or

$$y_j \Pi_j(p) = 0 \quad \forall_j$$

Furthermore, it follows that:

$$p_i \left(\sum_j y_j \frac{\delta \Pi_j(p)}{\delta p_i} + \sum_h \omega_{ih} - \sum_h d_{ih}(p, M_h) \right) = 0 \quad \forall_i$$

In other words, complementary slackness is a feature of the equilibrium allocation even though it is not imposed as an equilibrium condition, per-se. This means that in equilibrium, a production activity which is operated makes zero profit and any production activity which earns a negative net return is idle. Likewise, any commodity which commands a positive price has a balance between aggregate supply and demand, and any commodity in excess supply has an equilibrium price of zero.

4.49.2.3 A small example: Harberger

This section of the paper introduces *MPSGE* model building using a two- good, two-factor (2x2) example. This is addressed to readers who may be unfamiliar with *GAMS* and/or the original (scalar) *MPSGE* syntax. The discussion provides some details on the formulation and specification of one small model from the *MPSGE* library. Subsequently, two extensions are presented, one which illustrates equal yield constraints and another which introduces a pure public good. These examples are by no means exhaustive of the classes of equilibrium structures which can be investigated using the software, but they do provide a starting point for new users.

The structure of *MPSGE* model **HARBERGER** is "generic" Arrow-Debreu with taxes. Households obtain income by supplying factors of production to industry or collecting tax revenue. This income is then allocated between alternative goods in order to maximize welfare subject to the budget constraint.

Firms operate subject to constant returns to scale, selecting factor inputs in order to minimize cost subject to technological constraints. For an algebraic description of a model closely related to this one, see Shoven and Whalley (1984). The present model differs in two respects from the Shoven-Whalley example. First, in this model there are intermediate inputs to production while in the Shoven-Whalley model goods are produced using only value-added. Second, this model incorporates a labor-leisure choice so that the excess burden of factor taxes here incorporates the disincentive to work associated with a lower net wage.

Benchmark Data

Table 1 presents most of the input data for a two good, two factor, closed economy model. This is an economy in which, initially, taxes are levied only on capital inputs to production. We treat tax revenue as though it were returned lump-sum to the households.

	Sectors		Consumers		
	X	Y	OWNERS	WORKERS	GOVT
PX	100	-20	-30	-50	
PY	-10	80	-40	-30	
PK	-20	-40	60		
PL	-50	-10		100	-40
TRNS			10	20	-30
TK	-20	-10			30

The input data is presented in the form of a balanced matrix, the entries in which represent the value of economic transactions in a given period (typically one year). Social accounting matrices (SAMs) can be quite detailed in their representation of an economy, and they are also quite flexible. All sorts of inter-account taxes, subsidies and transfers can be represented through an appropriate definition of the accounts.

Traditionally, a SAM is square with an exact correspondence between rows and columns. (For an introduction, see Pyatt and Round, "Social Accounting Matrices: A Basis for Planning", The World Bank, 1985.) The numbers which appear in a conventional SAM are typically positive, apart from very special circumstances, whereas the rectangular SAM displayed in Table 1 follows a sign convention wherein supplies or receipts are represented by positive numbers and demands or payments are represented by negative numbers. Internal consistency of a rectangular SAM implies that row sums and column sums are zero. This means that supply equals demand for all goods and factors, tax payments equal tax receipts, there are no excess profits in production, the value of each household expenditure equals the value of factor income plus transfers, and the value of government tax revenue equals the value of transfers to households.

With simple *MPSGE* models, it is convenient to use a *rectangular* SAM format. This format emphasizes how the *MPSGE* program structure is connected to the benchmark data. In the rectangular SAM, we have one row for every market (traded commodity). In the present model, there are four markets, for goods X and Y and factors L and K .

There are two types of columns in the rectangular SAM, corresponding to production sectors and consumers. In the present model, there are two production sectors (X and Y) and three consumers (OWNERS, WORKERS and GOVT).

Data Entry in GAMS

Consider a generalized version of the model in which the set of production sectors be denoted S (here, $S = \{X, Y\}$). Let the set of goods be G . Production sectors are mapped one-to-one with the goods, so we see that sets S and G are in fact the same set. Let F denote the set of primary factors (here, $F = L, K$), and let H denote the set of households (here $H = \{\text{OWNER}, \text{WORKER}\}$). Now that we have identified the underlying sets, we may interpret the input matrix as a set of parameters with which we can easily specify the benchmark equilibrium. (See Table 2.) It is quite common to begin a general equilibrium modeling project with a large input-output table or social accounting matrix which may then be mapped onto a number of submatrices, each of which is dimensioned according to the underlying sets used in the model.

	Sectors	Consumers	
	(S)	Households(H)	Government
Goods Markets (G):	$A(G,S)-B(G,S)$	$-C(G,H)$	
Factor Markets (F):	$-FD(F,S)$	$E(F,H)-D(F,H)$	
Capital taxes:	$-T("K",S)$		GREV
Transfers:		TRN(H)	-GREV

The *GAMS* specification of benchmark data is presented in Table 3 which begins with a statement of the underlying sets (G, F, H). The statement "ALIAS (S,G)"; simply says that S and G both reference X, Y . Thereafter follows the social accounting data table and declarations for the various submatrices. The parameters ELAS() and ESUB() are elasticities ("free parameters") which can be chosen independently from the benchmark accounts. The parameters TF and PF are calibrated tax and reference price arrays which are computed given benchmark factor and tax payments. (In this model, average and marginal tax rates are not distinguished, so the benchmark marginal tax rate is simply the tax payment divided by the net factor income.)

A general equilibrium model determines only relative prices. For purposes of reporting or constructing value-indices, we use Laspeyres quantity index, THETA(G), the elements of which correspond to shares of aggregate consumer expenditure in the benchmark period.

Table 3: Data Specification in *GAMS* for the 2x2 Model Harberger

*	SECTION (i)	DATA SPECIFICATION AND BENCHMARKING

```

Model Specification

The *MPSGE* description of this model is shown in [Table 4](#). Declarations following the `$MODEL` statement indicate that the model involves one class of production activities ($AL(S)$), three classes of commodities ($P(G)$, $W(F)$ and PT), and two types of consumers, private consumers ($RA(H)$), and a government "consumer" (GOVT).

One `$PROD:` block describes the single class of production activities, and two `$DEMAND:` blocks characterize endowments and preferences for the two classes of consumers.

Consider the records associated with production sector $AL(S)$. The entries on the first line of a `$PROD:` block are elasticity values. The "s:0" field indicates that the top-level elasticity of substitution between inputs is zero (Leontief). The entry "a:ELAS(S)" indicates that inputs identified as belonging to the "a:" aggregate trade off with an elasticity of substitution $ELAS(S)$ (at the second level of the production function). In these production functions, the primary factors ($W(F)$) are identified as entering in the a : *aggregate*.

The records within a \$PROD: block begin with "O:" or "I:". An "O:" indicates an output and an "I:" represents an input. In both types of records, "Q:" is a "quantity field" indicating a reference input or output level of the named commodity. A "P:" signifies a reference price field. This price is measured as a user cost, gross of applicable taxes. The default values for reference price and reference quantity are both unity (i.e., a value of 1 is installed if a P: or Q: field is missing).

The A: and T: fields in a \$PROD: block indicate tax agent and ad-valorem tax rate, respectively. The tax agent is specified before the tax rate. A single input or output coefficient may have two or more taxes applied. Consumers are treated symmetrically, and there is thus no restriction on the consumer to whom the tax is paid. Typically, however, one consumer is associated with the government.

To better understand the relationship between reference prices and tax rate specification, consider inputs of $W.K$ to sector $AL.X$ in this model. The benchmark payment to capital in the X sector is 20 and the tax payment is 20. Hence the ad-valorem tax rate in the benchmark equilibrium is 100% ($T: 1$), and the reference price of capital, market price of unity times $(1 + 100\%)$, is 2 ($P: 2$). If in a counterfactual experiment the tax rate on capital inputs to sector X is altered, this will change the $T:$ field but it will

not change the P : field. Q : and P : characterize a reference equilibrium point, and these are therefore unaffected by subsequent changes in the exogenous parameters.

It is important to remember that the `$PROD:AL(S)` block represents as many individual production functions as there are elements in set S (two in this case). Within the `$PROD:AL(S)` block, inputs refer to sets G and F , while the output coefficient, $O : P(S)$, refers only to set S . Sets referenced within a commodity name in an I : or O : field may be sets which are "controlled" by the sets referenced in the function itself, in which case only a scalar entry is produced. In `$PROD:AL(S)` there are only outputs of commodity S in sector S .

The first line of a `$DEMAND` block also contains fields (e.g., `s:`, `a:`, `b:` etc.) which represent elasticities of substitution. The subsequent records may begin with either an E : field or a D : field. These, respectively, represent commodity endowments and demands. In the demand fields, the P : and Q : entries are interpreted as reference price and reference quantity, analogous to the input fields in a `$PROD` block. Ad-valorem taxes may not be applied on final demands, so that if consumption taxes are to be applied in a model they must be levied on production activities upstream of the final demand.

The benchmark values for all activity levels and prices are equal to the default value of unity, and therefore we are able to specify values in the Q : fields directly from the benchmark data. An equivalent model could be specified in which the benchmark activity levels for `AL(S)` equal, for example, `A(S,S)`. This would then require rescaling the input and output coefficients for those sectors, and it would not necessarily be helpful, because in a scaled model it is more difficult to verify consistency of the benchmark accounts and MPSGE input file. Furthermore, for numerical reasons it is advisable to scale equilibrium values for the central variables to be close to unity.

Government transfers to households are accomplished through the use of an "artificial commodity" (PT). The government is identified as the agent who receives all tax revenue (see the `A:GOVT` entry in both of the `$PROD:` blocks). Commodity PT is the only commodity on which `GOVT` spends this income, hence government tax revenue is divided between the two households in proportion to their endowments of the artificial good. In order to scale units so that the benchmark price of PT is unity, the \$30 of government tax revenue chases 10 units of PT assigned to `OWNER` and 20 units assigned to `WORKER`. (See values for `TRN(H)` in [Table 3](#).)

The `$REPORT` section of the input file requests the solution system to return values for inputs, outputs, final demands or welfare indices at the equilibrium. Only those items which are requested will be written to the solution file. Each record in the report block begins with a V : (variable name) field. These names must be distinct from all other names in the model. The second field of the report record must have one of the labels I :, O : or D : followed by a commodity name, or the label W : followed by a consumer name. The third field's label must be "PROD:" in an I : or O : record, and it must be "DEMAND:" if it is a D : record.

An [algebraic formulation of the Harberger model](#) is provided for the interested reader.

MPSGE Formulation: Key Ideas

There are two points regarding the MPSGE function format which are important yet easily misunderstood by new users:

1. *The elasticities together with the reference quantities and reference prices of inputs and outputs completely characterize the underlying nested CES functions.* No other data fields in the `$PROD:` block alters the technology. If, for example, a tax rate changes as part of a counter-factual experiment, this has no effect on the reference price. The value in the P : field depends on the benchmark value of the T : field if the model has been calibrated, but subsequent changes in T : do not change the underlying technology.
2. *Tax rates are interpreted differently for inputs and outputs.* The tax rate on inputs is specified on a net basis, while the tax rate on outputs is specified on a gross basis. That is, the user cost of an input with market price p subject to an ad-valorem tax at rate t is $p(1 + t)$, while the user cost of an output subject to an ad-valorem tax at rate t is $p(1 - t)$. (A tax increases the producer cost of inputs and decreases the producer value of outputs.)

MPSGE provides a limited number of economic components with which complex models can be constructed. There are some models which lie outside the *MPSGE* domain, but in many cases it is possible to recast the equilibrium structure in order to produce an *MPSGE* model which is logically equivalent to the original model - usually after having introduced some sort of artificial commodity or consumer. In the present model, the use of commodity PT to allocate government revenue between households provides a fairly typical example of how this can be done. In the process of making such a transformation, one often gains a meaningful economic insight.

The Solution Listing

The detailed solution listing for model HARBERGER is shown in Table 5. The standard *GAMS* report facilities display solution values. Central variables are always either fixed (upper = lower), or they are non-negative (lower bound = 0, upper bound = +INF). The MARGINAL column in the solution report returns the value of the associated slack variable. Complementarity implies that in equilibrium, either the level value of a variable will be positive or the marginal value will be positive, but not both.

The output file (not shown) also provides details on the computational process. For an explanation of these statistics, see Rutherford (1993).

Computing Counter-factual Scenarios

Table 6 presents the *GAMS* code for specification and solution of three counterfactual equilibria. In these experiments, the nonuniform system of capital taxes from the benchmark is replaced by three alternative uniform factor tax structures: a tax on labor, a tax on capital, and a tax on both labor and capital. In each case, the tax rate is chosen to replace the benchmark tax revenue at benchmark prices and demand (ignoring induced substitution effects). Following each solution, the equilibrium values for tax revenue, welfare (Hicksian equivalent variation), employment, prices and output are stored in parameter **REPORT**.

4.49.2.4 Alternative models: Shoven and Samuelson

The "standard" *MPSGE* model is based on fixed endowments and tax rates, but many empirical models do not fit into this structure. For example, in the model **HARBERGER**, the level of each replacement tax was specified to be consistent with "equal yield", but as a result of the endogenous response of prices and quantities, the resulting tax revenues differed significantly from the benchmark levels. For example, when the capital tax is replaced by a uniform labor tax at a rate which, in the absence of labor supply response, produces "equal yield", we find that tax revenue in fact declines by 39%. In order to perform differential (equal yield) tax policy analysis, it is therefore necessary to accommodate the endogenous determination of tax rates as part of the equilibrium computation. This is one of many possible uses of "auxiliary variables" in *MPSGE*.

Tax Analysis with Equal Yield

[Table 7](#) presents the *MPSGE* model definition for test problem **SHOVEN**. This model is equivalent to the **HARBERGER**, apart from the addition of an auxiliary variable **TAU**. Within *MPSGE*, auxiliary variables can either represent price-adjustment instruments (endogenous taxes) or they can represent a quantity-adjustment instruments (endowment rations). In model **SHOVEN**, **TAU** is used to proportionally scale factor taxes in order to achieve a target level of government revenue. The auxiliary variable first appears in the **\$PROD:AL(S)** block, following the declaration of a tax agent. There are two fields associated with an endogenous tax. The first field (**N:**) gives the name of the auxiliary variable which will scale the tax rate. The second field (**M:**) specifies the multiplier. If the **M :** field is omitted, the multiplier assumes a default value of unity. If the value in the **M :** field is zero, the tax does not apply.

The auxiliary variable **TAU** also appears at the bottom of the file where it labels an associated inequality constraint. This constraint exhibits complementary slackness with the associated non-negative auxiliary variable (i.e., if **TAU** is positive, the constraint must hold with an equality, whereas if the constraint is non-binding **TAU** must be zero). An auxiliary variable may or may not appear in its associated constraint.

The constraint associated with TAU is based on a price index defined by THETA(G). The constraint assures a level of tax revenue such that the value of transfers to households is held constant. (Endowments of the commodity PT are fixed, so when the value of PT is fixed, then so too are the value of transfers from GOVT to each of the households.)

SHOVEN illustrates how an auxiliary variable can be interpreted as a tax instrument. In the *MPSGE* syntax, auxiliary variables may also be employed to endogenously determine commodity endowments. There is no restrictions on how a particular auxiliary variable is to be interpreted. A single variable could conceivably serve simultaneously as an endogenous tax as well as a endowment ratio, although this would be rather unusual.

An [algebraic formulation of the Shoven model](#) is provided for the interested reader.

Public Goods and Endogenous Taxation

Consider a final extension of the 2x2 model in which tax revenue funds a pure public good. Model SAMUELSON presented in Table 8. This model illustrates one of several ways that public goods can be modelled in *MPSGE*. Here the level of public provision is determined by a Samuelson-condition equating the sum of individual marginal rates of substitution (marginal benefit) with the marginal rate of transformation (marginal cost). Unlike the equal yield formulation, the tax revenues collected by GOVT are not returned lump-sum but are instead used to finance provision of a pure public good. This representation of government has not been widely adopted in the CGE literature, perhaps because of the difficulties involved in specifying preferences for public goods.

The relevant characteristic of a pure public good entering final demand is that each consumer "owns" the same quantity. Agents' attitudes toward public goods differ, and because there is no market, agents' valuations of the public good will also differ. In an *MPSGE* model, the separate valuations are accommodated through the introduction of "personalized" markets for public good - one market for each consumer. In the model, consumer expenditure encompasses both private and public "purchases", and consumer income encompasses both private and public "endowments". An individual is endowed with a quantity of her own version of the public good determined by the level of public expenditures. An increase in taxes, to the extent that it increases tax revenue, will increase the level of public provision.

In this model, the structure of relative factor taxes is exogenous but the aggregate level of taxes is not. Tax rates are scaled up or down so that the sum of individual valuations of the public good (the marginal benefit) equals the cost of supply of the public good (the direct marginal cost).

Consider features of model SAMUELSON which do not appear in SHOVEN:

1. There are new commodities PG and VG(H). The first of these represents the direct marginal cost of public output from sector GP, a Leontief technology which converts private goods inputs into the public good. For the SAMUELSON structure, all government revenues apply to purchases of the public good (observe that the only good demanded by consumer GOVT is PG). The prices VG(H) represent the individual consumer valuations of the public good. Commodity VG(H) appears only in the endowments and demands of consumer RA(H). The endowment record for VG(H) includes a quantity V(H) which is the benchmark valuation of the public good by agent H.
2. There are two auxiliary variables. TAU has the same interpretation as in the SHOVEN, determining the aggregate tax level. Auxiliary variable LGP is a rationing instrument representing an index of the "level of public goods provision", scale to equal 1 in the benchmark. Consumer RA(H) thus is endowed with a quantity of VG(H) given by $V(H) * LGP$.
3. The constraint for TAU in SAMUELSON differs from the TAU constraint in SHOVEN. Here the constraint represents the Samuelson condition, equating the marginal cost ($PG * GREV$) and the sum of individuals' marginal benefit ($SUM(H, VG(H) * V(H))$). The constraint for LGP simply assigns LGP equal to the sector GP activity level. (The LGP variable and constraint are only needed because the R: field only accepts auxiliary variables.)

Comparing Model Results

Although the foregoing discussion has focused on the nuances of *MPSGE* model syntax, but there are many interesting economic questions which can be addressed using even small-scale models such as the ones described here. Consider the output listing from parameter REPORT is displayed in [Table 9](#). It is perhaps surprising to note that none of the uniform tax structures represents a Pareto-superior choice compared to the benchmark tax structure. Furthermore, from the standpoint of aggregate welfare ("WELFARE.TOTAL" = income-weighted sum of individual EV's), only the uniform capital tax represents an improvement.

4.49.2.5 Summary

This paper has provided an introduction to a new *GAMS* subsystem for applied general modeling. This extension of *GAMS* accommodates a tabular representation of highly nonlinear cost and expenditure functions through which model specification is concise and transparent. The paper has presented three small examples which illustrate the programming environment and its application to traditional economic issues in public finance for which applied general equilibrium analysis is a standard tool. Further work is underway in the development and evaluation of solution algorithms for applied general equilibrium models implemented within *GAMS/MPSGE*. In addition to providing a convenient framework for model-builders, the new *GAMS/MPSGE* system also simplifies the implementation and testing of algorithms for complementarity problems. Information on the relative effectiveness of different solution strategies should prove quite helpful to users who are using the system to solve very large systems of nonlinear equations.

4.49.2.7 Appendix A: Language Syntax

General syntax rules

- All input is free format (spaces and tabs are ignored) except keywords for which "\$" must appear in column 1.
- End-of-line is significant. Continuation lines are indicated by a "+" in column 1.
- In general, input is not case sensitive, except in the specification of sub-nests for production and demand functions.
- Numeric expression involving GAMS parameters or constants must be enclosed in parentheses.

Keywords

Keywords typically appear in the following order:

Keywords	Description
\$ONTEXT	Indicate the beginning of a GAMS comment block containing an MPSGE model.
\$MODEL:model_name	<i>model_name</i> must be a legitimate file name. This name is subsequently used to form MODEL_NAME.GEN (this file name must be upper case when running under UNIX).
\$SECTORS:, \$COMMODITIES:, \$AUXILIARY:, \$CONSUMERS:	Four keywords define variables which are used in the model. Entries in these blocks share the same syntax. The \$AUXILIARY block is only used in models with side constraints and endogenous taxes or rationed endowments.
\$PROD:sector	Production functions must be specified for each production sector in the model.
\$DEMAND:consumer	Demand functions must be specified for every consumer in the model. General structure is the same as for production functions above.

Keywords	Description
\$CONSTRAINT:auxiliary	Specifies a side constraint to be associated with a specified auxiliary variable.
\$REPORT:	Identifies the set of additional variables to be calculated. These include outputs and inputs by sector and demands by individual consumers.
\$OFFTEXT	Indicates the end of model specification.

Variable Declarations

There are four classes of variables within an *MPSGE* model: activity levels for production sectors, prices for commodities, income levels for consumers and level values for auxiliary variables. These classes of variables are distinguished in order to permit additional semantic checking by the *MPSGE* preprocessor. For example, if P has been declared as a price (within the \$COMMODITIES: block), then the preprocessor would report an error if it encountered "\$PROD:P".

The \$SECTORS:, \$COMMODITIES:, \$CONSUMERS: and \$AUXILIARY: blocks contain implicit *GAMS* variable declarations in which the index sets must be specified in the *GAMS* program above and the variable names must be distinct from all other symbols in the *GAMS* program. One or more variables may be declared per line separated by one or more spaces.

```
$SECTORS:
      Y(R,T)      ! Output in region R in period T
      K(T)        ! "Aggregate capital stock, period T"
```

In these declarations, the trailing comments (signified by "!") are interpreted as variable name descriptors which subsequently appear in the solution listing.

The equivalent *GAMS* declaration for these variables would be:

```
VARIABLES  Y(R,T)  Output in region R in period T
            K(T)    "Aggregate capital stock, period T";
```

As with the usual *GAMS* syntax, when a variable descriptor contains a punctuation symbol such as ",", it is required to be enclosed in quotes.

```
$SECTORS:
      X(R,T)$ (X0(R) GT 0)
```

Here, the *GAMS* conditional operator "\$" is used to restrict the domain of the variable X. The expression following the dollar sign is passed through to the *GAMS* compiler and must conform to *GAMS* syntax rules.

```
$SECTORS:
      X Y(R)$Y0(R) Z      ! Descriptor for Z
      W(G,R,T)            ! Descriptor for W
```

More than one symbol may appear on a single line. The descriptor only applies to the last one.

All *MPSGE* variables must be declared. When multidimensional variables are specified, they must be declared explicitly - declarations like $X(*)$ are not permitted. Two further restrictions are that the sets used in the declaration must be static rather than dynamic, and any variable which is declared must be used in the model. There is a simple way to work around these restrictions. Let me illustrate with an example. Suppose that in a model the set of production sectors AL is employed for all elements of a static set S which satisfy a particular condition, for example $BMX(S)$ not equal to 0. This would require that AL be declared as follows:

```
$SECTORS:
    AL(S)$BMX(S)
```

In this context, the symbol "\$" is used as an "exception operator" which should be read as "such that". In this case, we have generated one AL sector for each element of the set S for which $BMX(S)$ is nonzero.

Function Declarations

Functional declarations characterize nested CES functions which characterize both preferences and technology. The former are written within a $\$DEMAND$: block and the latter within a $\$PROD$: block. Tax entries may appear within a $\$PROD$: block but not within a $\$DEMAND$: block, otherwise the syntax is nearly identical. The syntax for these blocks will be described through a sequence of examples:

```
$PROD:Y(R)   s:1
O:P(R)       Q:Y0(R)
I:W(F,R)     Q:F0(F,R)
```

This block characterizes a Cobb-Douglas production function in which the elasticity of substitution between inputs is one - " $s:1$ " in the first line which sets a top level substitution elasticity equal to unity. Variable $Y(R)$ is an activity level declared within the $\$SECTORS$: block. Variables $P(R)$ and $W(F,R)$ are prices declared within the $\$COMMODITIES$: block. The O : label indicates an output, and the I : prefix indicates an input. The Q : fields in both records represent "reference quantities". $Y0(R)$ and $F0(F,R)$ must be GAMS parameters defined previously in the program.

```
$PROD:X(R)   s:ESUB(R)   a:0   b:(ESUB(R)*0.2)
O:PX         Q:X0(R)
I:PY(G)      Q:YX0(G,R)   a:
I:PL         Q:LX0(R)     b:
I:PK         Q:KX0(R)     b:
```

The keyword line specifies three separate elasticities related to this function. $ESUB(R)$ is the top level elasticity of substitution. There are two sub-nests in the function. Nest a : is a Leontief nest (in which the compensated elasticity is zero). The elasticity of substitution in nest b : is one-fifth of the top level elasticity.

In the function specification, commodities $PY(G)$ (one input for each element of set G) enter in fixed proportions. Commodities PL and PK enter in nest b .

If this function has been specified using a balance benchmark dataset with reference prices equal to unity, then the following identity should be satisfied:

$$X0(R) = \text{SUM}(G, YX0(G,R)) + LX0(R) + KX0(R)$$

```

$PROD:AL(S)  s:0  a:ELAS(S)
O:P(G)      Q:A(G,S)
I:P(G)      Q:B(G,S)
I:W(F)      Q:FD(F,S)  P:PF(F,S)  A:GOVT  T:TF(F,S)  a:

```

In this function, we have two new ideas. The first is the use of a reference price denoted by "P:". This entry indicates that the function should be calibrated to a reference point where individual input prices (gross of tax) equal PF(F,S). If P: does not appear, prices of one are assumed.

The second new idea here is that taxes may be levied on production inputs. The A: label identifies the name of the tax agent (a \$CONSUMER:). The T: label identifies the ad-valorem tax rate.

```

$DEMAND:RA(R)$RAO(R)  s:1
E:PL                  Q:LE(R)
D:P(G)$DG(G)         Q:DO(G,R)$DD(G,R)  P:PO(G,R)

```

This function specification demonstrates the use of conditionals. This function is only generated when RAO(R) is nonzero. The demands D: for a particular element of set G are suppressed entirely when DG(G) equals 0. The Q: field also has an exception operator, so that the default value for Q: (unity) is applied when DD(G,R) equals zero.

This example is somewhat artificial, but it illustrates the distinction between how exception operators affect lead entries (I:, O:, D: and E:) and subsequent entries. When an exception is encountered on the lead entry, the entire record may be suppressed. Exceptions on subsequent entries only applied to a single field.

The valid labels in a function declaration (\$PROD: or \$DEMAND:) line include:

- s: Top level elasticity of substitution between inputs or demands.
- t: Elasticity of transformation between outputs in production. (valid only in \$PROD blocks)
- a:,b:,... Elasticities of substitution in individual input nests.

The recognized labels in an I: or O: line include:

- Q: Reference quantity. Default value is 1. When specified, it must be the second entry.
- P: Reference price. Default value is 1.
- A: Tax revenue agent. Must be followed by a consumer name.
- T: Tax rate field identifier. (More than one tax may apply to a single entry.)
- N: Endogenous tax. This label must be followed by the name of an auxiliary variable.
- M: Endogenous tax multiplier. The advalorem tax rate is the product of the value of the endogenous tax and this multiplier.
- a:,b:,... Nesting assignments. Only one such label may appear per line.

The valid labels in an E: line include:

- Q: Reference quantity
- R: Rationing instrument indicating an auxiliary variable.

The valid labels in a D: line include:

Q: Reference quantity

P: Reference price

a:,b:... Nesting assignment

Constraints

Auxiliary constraints in *MPSGE* models conform to standard *GAMS* equation syntax. They may refer to any of the four classes of variables, \$SECTORS, \$COMMODITIES, \$CONSUMERS and \$AUXILIARY, but they may not reference variable names declared within a \$REPORT block. Complementarity conditions apply to upper and lower bounds on auxiliary variables and the associated constraints. For this reason, the orientation of the equation is important. When an auxiliary variable is designated POSITIVE (the default), the auxiliary constraint should be expressed as a "greater or equal" inequality (=G=). If an auxiliary variable is designated FREE, the associated constraint must be expressed as an equality (=E=).

```
$CONSTRAINT:TAU
                G =G= X * Y;
$CONSTRAINT:MU(I)$MUO(I)

                MU(I) * P(I) * Q(I) =G= SUM(J, THETA(I,J) * PX(J));
```

The exception applied in this example restricts the equation only to those elements of set I for which MUO(I) is not zero.

Report Declaration

The GAMS interface to MPSGE normally returns level values only for the central variables - those declared within \$SECTORS:, \$COMMODITIES:, \$CONSUMERS: and \$AUXILIARY: sections. An equilibrium determines not only these values, but also levels of demand and supply by individual sectors and consumers. Given benchmark information, elasticities and the equilibrium values, all such demands can be computed, but this can be tedious to do by hand. In order to have these values returned by MPSGE, it is necessary to indicate the name of the variable into which the value is to be returned. The general form is as follows:

```
$REPORT:
V:variable name   I:commodity   PROD:sector
V:variable name   O:commodity   PROD:sector
V:variable name   D:commodity   DEMAND:consumer
V:variable name   W:consumer
```

The first row returns an input quantity, the second row returns an output quantity, the third returns a demand quantity, and the fourth row returns a consumer welfare index. (Note: the level value returned for a "consumer variable" is an income level, not a welfare index.)

```
$REPORT:
V:DL(S)           I:PF("L")       PROD:Y(S)
V:DK(S)           I:PF("K")       PROD:Y(S)
V:SX(G,S)$SX0(G,S) O:PX(G)       PROD:X(S)
V:D(G,H)          D:P(G)          DEMAND:RA(H)
V:W(H)            W:RA(H)
```

Note that the "\$" exception is only meaningful on the first entry. Also notice that the domain of the report variable must conform to the domain of the subsequent two entries.

Differences between Scalar and Vector *MPSGE Syntax*

1. **\$MODEL:** statement The **\$MODEL** statement is required in the vector format and it must precede all other statements. A name which is an acceptable file name prefix must be used. The preprocessor does not begin translation of an *MPSGE* model until it encounters a **\$MODEL** statement following an **\$ONTEXT** record. The preprocessor continues to translate until it reaches an **\$OFFTEXT** statement, skipping blank lines and comment lines identified by a "*" in column 1.
2. **Case folding:** In the vector syntax, upper and lower case letters are not distinguished. The entire file is processed as though it were written in upper case. This is not compatible with the earlier version of *MPSGE* in which "P" and "p" were distinct.
3. **Distinct names:** Names used for variables in the *MPSGE* model must be distinct from each other as well as from all other symbols in the *GAMS* program. If there is a *GAMS* set or parameter or model named X, then X may not be used to identify an *MPSGE* sector or commodity.
4. **Tabs:** *MPSGE* fields are free format and tabs are translated to spaces by the preprocessor. Tabs are permitted in *GAMS* provided that the compiler is properly configured (under DOS, "TABIN 8" must be inserted in file *GAMSPARM.TXT* in the *GAMS* system directory).

Exception Handling

The *GAMS* exception operator can be used on virtually any entry in the *MPSGE* input file. For example, if you want to have sector X(S) have one production structure for elements S in a subset T(S), you can provide separate production function declarations as follows:

```
$PROD:X(S)$T(S)
...           ! sector X described for S in T

$PROD:X(S)$ (NOT T(S))
...           ! sector X described for S not in T.
```

The preprocessor does not require one and exactly one declaration for each sector. If multiple declarations appear, the later set of coefficients overwrites the earlier set.

Switches and Debug Output

Run-time tolerances and output switches may be specified within the vector-syntax model specification or using the PUT facility, they can be written directly to the MPS input file. Output switches control the level of debug output written by the *MPSGE* subsystem to the solver status file. Reports provided by **\$ECHOP**, **\$FUNLOG** and **\$DATECH** can be returned to the listing file by specifying "OPTION SYSOUT=ON;" within the *GAMS* program prior to the SOLVE statement. The recognized *MPSGE* parameters are:

```
$ECHOP: logical          Default=.FALSE.
```

is a switch for returning all or part of the scalar *MPSGE* file to the solver status file. In order to have this output printed in the listing file, enter the *GAMS* statement "OPTION SYSOUT=ON;" prior to solving the model.

```
$PEPS:  real            Default=1.0E-6
```

is the smallest price for which price-responsive demand and supply functions are evaluated. If a price is below PEPS, it is perturbed (set equal to PEPS) prior to the evaluation.

\$EULCHK: logical Default=.TRUE.

is a switch for evaluating Euler's identity for homogeneous equations. The output is useful for monitoring the numerical precision of a Jacobian evaluation. When a price or income level is perturbed in a function, the Euler check may fail.

\$WALCHK: logical Default=.TRUE.

is a switch for checking Walras's law. Like EULCHK, this switch is provided primarily to monitor numerical precision. When an income level is perturbed, the Walras check may fail.

\$FUNLOG: logical Default=.FALSE.

is a switch to generate a detailed listing of function evaluations for all production sectors and consumers.

FUNLOG triggers a function evaluation report which provides detailed output describing the evaluation of supply and demand coefficients. The information provide is sufficient that an industrious graduate student should be able to reproduce the results (given a pencil, paper and slide rule).

The evaluation report has the following headings:

Heading	Description
T	Coefficient "type" with the following interpretation: IA Input aggregate OA Output aggregate I Input O Output D Demand E Endowment
N	Name (either nest identifier or commodity name)
PBAR	Benchmark price (the P: field value)
P	Current price (gross of tax)
QBAR	Benchmark quantity (the Q: field value)
Q	Current quantity
KP	Identifier for parent entry in nesting structure.
ELAS	Associated elasticity (input or output aggregates only)

When **\$FUNLOG: .TRUE** is specified, a complete report of demand and supply coefficients for every production and demand function in every iteration. Be warned that with large models this can produce an enrmous amount of output!

The following two function evaluation reports are generated in the first iteration in solving case "L" for model HARBERGER:

Function Evaluation for: AL.X

T	N	PBAR	P	QBAR	Q	KP	ELAS

E	PT	1.0000E+00	1.0000E+00	1.0000E+01	0.0000E+00		

\$DATECH: logical Default=.FALSE.

is a switch to generate a annotated listing of the function and Jacobian evaluation including a complete listing of all the nonzero coefficients.

MPSGE generates an analytic full first-order Taylor series expansion of the nonlinear equations in every iteration. Nonzero elements of the Jacobian matrix are passed to the system solver (*MILES* or *PATH*) which uses this information in the direction-finding step of the Newton algorithm. Coefficients are produced with codes which help interpret where they came from. The following codes are used:

- W0 indicates an element from the orthogonal part of F().
- W1 indicates an element from the non-orthogonal part of F().
- B indicates a linear term from F.
- E0 indicates a homogeneous Jacobian entry.
- E1 indicates a non-homogeneous Jacobian entry.

The Euler checksum examines elements from the linearization which are type "E0". The Walras checksum examines elements from the function evaluation which are type "W0".

Needless to say, the \$DATECH:.TRUE. switch produces a very big status file for large models. It is not something which is very useful for the casual user.

Here is a partial listing of nonzeros generated during the first linearization for scenario "L" in model HARBERGER:

----- Coefficients for sector:AL.X			
P.X	AL.X	1.0000E+02	B

4.49.2.8 Appendix B: File Structure

This appendix provides an overview of the structure of *GAMS* input files which include *MPSGE* models. The text of the paper presents many of these ideas by way of example, but it may also be helpful for some users to have a "template" for constructing *MPSGE* models. The discussion in this section focuses on a "generic" input file, the schematic form of which is presented in Table 10. This section first presents a "top down" view of program organization, and then it discusses aspects of the new syntax for model specification.

Flow of Control

When a model is developed using *GAMS* as a front-end to *MPSGE*, the input file generally has five sections as identified in Table 10. Section (i), the benchmarking section, contains standard *GAMS* statements. This includes *GAMS* SET declarations, input data (SCALARS, PARAMETERS and TABLES), and PARAMETER declarations for intermediate arrays used in benchmarking or model specification. In complex models, this section of the file will typically contain some algebraic derivations, the result of which is a calibrated benchmark equilibrium dataset.

Users who are unfamiliar with *GAMS* can consult the manual. Beginning *GAMS* programmers should remember that the *MPSGE* interface to *GAMS* is unlike other solution subsystems. "Level values" are passed between the *GAMS* program and *MPSGE* in the usual fashion, but *MPSGE* models do not require the explicit use of the VARIABLE or EQUATION statements.)

The second section of the file consists of a *GAMS* comment range, beginning with an \$ONTEXT record and ending with an \$OFFTEXT record, followed by an invocation of the preprocessor. The preprocessor

writes operates on statements in the *MPSGE* model declaration which are "invisible" to the *GAMS* compiler. This program reads the *MPSGE* model statements and generates *GAMS*-readable code, including a `model_name.gen` file. Additional *GAMS* code produced by the preprocessor includes declarations for each of the central variables and report variables in the *MPSGE* model.

The third section of the generic input file performs a "benchmark replication" and may not be present in all applications. There are four statements required for benchmark validation. The first statement sets the iteration limit to be zero; the second statement causes the *MPSGE* model to be "generated", and the third statement causes the *MPSGE* solver to read the model and return the deviations. In this call, the level values passed to the solver are unaltered because the iteration limit is zero. Market excess supplies and zero profit checks are returned in the "marginals" of the associated commodity prices and activity levels, respectively. The final statement in this section resets the iteration limit to 1000 (the default value) for subsequent counter-factual computations.

Section (iv) defines and then computes a counter-factual equilibrium. A counter-factual equilibrium is defined by parameter values such as tax rates or endowments which take on values different from those in the benchmark equilibrium. Within the *GAMS* interface to *MPSGE*, it is also possible to fix one or more central variables. When any variable is fixed, the associated equation is omitted from the equilibrium system during the solution process but the resulting imbalance is then reported in the solution returned through the marginal.

The final section of the file represents the *GAMS* algebra required for comparing counter-factual equilibria. It would be possible, for example, to construct welfare measures or to report percentage changes in certain values. All of these calculations are quite easy because the equilibrium values are returned as level values in the associated variables.

The final section of the file represents the *GAMS* algebra required for comparing counter-factual equilibria. It would be possible, for example, to construct welfare measures or to report percentage changes in certain values. All of these calculations are quite easy because the equilibrium values are returned as level values in the associated variables.

For large models, the advantage of the vector format is that by using appropriately defined *GAMS* sets, the number of individual functions which need to be defined is reduced only to the number of "classes" of functions. This makes it possible to represent large dimensional models using only a few lines of code.

To summarize, here are the basic features of a program which uses *GAMS* as a front-end to *MPSGE*:

1. An *MPSGE* model is defined within a *GAMS* comment range followed by

```
$sysinclude mpsgeset model_name
```
2. Every `SOLVE` statement for a particular model is preceded by `$INCLUDE MODEL.GEN`. The GEN file is written by the preprocessor based on the model structure.
3. Solution values for the central variables in the *MPSGE* model and any declared "report variables" are returned in *GAMS* variable level values. Level values for slacks are returned as "marginals" for the associated variables.
4. The model description follows a format which is a direct extension of the scalar data format. Certain aspects of the new language, such as case folding, are incompatible with the original *MPSGE* syntax.

***GAMS* Code Generated by the Preprocessor: the GEN File**

Most novice users will find it easiest to treat the preprocessor output files as "black boxes". These files contain *GAMS* source code required for declaring and generating the *MPSGE* input file. Table 11 contains portions of the GEN file for the same model. Table 12 shows the preprocessor-generated listing and symbol table which are always appended to the bottom of the GEN file. If a preprocessor error occurs, it can be helpful to consult the symbol table to track down the bug. Finally, Table 13 shows the first page of scalar format *MPSGE* input file produced by `HARBERGER.GEN`. Normally, this file is written and then erased in the course of a *GAMS* run, although all or part of the file may be retained using the `$ECHO: switch`.

4.49.3 Demand Theory and General Equilibrium: An Intermediate Level Introduction to MPSGE

This research supported by the *GAMS* Applied General Equilibrium Research Fund. The software described here operates only with *GAMS* 2.25.085 or later on the PC, shipped in July, 1995. The author remains responsible for any bugs which exist in this software.

Thomas F. Rutherford, rutherford@colorado.edu Department of Economics University of Colorado

1995 :

4.49.3.1 An Overview

This document describes a mathematical programming system for general equilibrium analysis named *MPSGE* which operates as a subsystem to the mathematical programming language *GAMS*. *MPSGE* is library of function and Jacobian evaluation routines which facilitates the formulation and analysis of AGE models. *MPSGE* simplifies the modeling process and makes AGE modeling accessible to any economist who is interested in the application of these models. In addition to solving specific modeling problems, the system serves a didactic role as a structured framework in which to think about general equilibrium systems.

MPSGE separates the tasks of model formulation and model solution, thereby freeing model builders from the tedious task of writing model-specific function evaluation subroutines. All features of a particular model are communicated to *GAMS/MPSGE* through a tabular input format. To use *MPSGE*, a user must learn the syntax and conventions of this model definition language.

The present paper is intended for students who have completed two semesters of study in microeconomics. The purpose of this presentation is to give students a practical perspective on microeconomic theory. The diligent student who works through all of the examples provided here should be capable of building small models "from scratch" to illustrate basic theory. This is a first step to acquiring a set of useable tools for applied work.

The remainder of this paper is organized as follows. Section [The Theory of Consumer Demand](#) review the theory of consumer demand; section [Getting Started](#) provides guidance on the mechanics of numerical modeling, including instructions on how to install and test the *GAMS/MPSGE* software; section [Modeling Consumer Demand](#) introduces the modeling framework with three models illustrating the representation of consumer demand within the *MPSGE* language. Section [The Pure Exchange Model](#) reviews the pure exchange model, and section [Modeling Pure Exchange with MPSGE](#) presents two *MPSGE* models of exchange. Each of the model- oriented sections present exercises based on the models which give students a chance to work through the material on their own. Additional introductory examples for self-study can be found in the [Markusen Library](#) as well as in the *GAMS* model library (look for models with names ending in "MGE").

The level of presentation and diagrammatic exposition adopted here is based on Hal Varian's undergraduate microeconomics textbook (*Intermediate Microeconomics: A Modern Approach*, Third Edition, W. W. Norton & Company, Inc., 1993).

The ultimate objective of this piece is to remind students of some theory which they have already seen and illustrate how these ideas can be used to build numerical models using *GAMS* with *MPSGE*. It is not my intention to provide a graduate level presentation of this material. So far as possible, I have avoided calculus and even algebra. The objective here is to demonstrate that what matters are economic ideas. With the proper tools, it is possible to do concrete economic modeling without a lot of mathematical formalism.

4.49.3.2 The Theory of Consumer Demand

A central idea underlying most microeconomic theory is that agents optimize subject to constraints. The optimizing principle applied to consumer choice begins from the notion that agents have preferences over consumption bundles and will always choose the most preferred bundle subject to applicable constraints. To operationalize this theory, three issues which must be addressed:

1. How can we represent preferences?
2. What is the nature of constraints on consumer choice? and
3. How can the choice be modelled?

Preferences are relationships between alternative consumption "bundles". These can be represented graphically using "indifference curves", as illustrated in [Figure 1](#). Focusing now on the preferences of a single consumer, the indifference curve is a line which connects all combinations of two goods x and y between which our consumer is indifferent. As this curve is drawn, we have represented an agent with "well-behaved preferences": at any allocation, more is better (monotonicity), and averages are preferred to extremes (convexity). Exactly one such indifference curve goes through each positive combination of x and y . Higher indifference curves lie to the "north-east".

Figure 1: An Indifference Curve

If we wish to characterize an agent's preferences, the "marginal rate of substitution" (MRS) is a useful point of reference. At a given combination of x and y , the marginal rate of substitution is the slope of the associated indifference curve. As drawn, the MRS increases in magnitude as we move to the northwest and the MRS decreases as we move to the south east. The intuitive understanding is that the MRS measures the willingness of the consumer to trade off one good for the other. As the consumer has greater amounts of x , she will be willing to trade more units of x for each additional unit of y – this results from convexity.

An "ordinal" utility function $U(x, y)$ provides a helpful tool for representing preferences. This is a function which associates a number with each indifference curve. These numbers increase as we move to the northeast, with each successive indifference curve representing bundles which are preferred over the last. The particular number assigned to an indifference curve has no intrinsic meaning. All we know is that if $U(x_1, y_1) > U(x_2, y_2)$, then the consumer prefers bundle 1 to bundle 2.

Figure 2 illustrates how it is possible to use a utility function to generate a diagram with the associated indifference curves. This figure illustrates Cobb-Douglas well-behaved preferences which are commonly employed in applied work.

Figure 2: Indifference Curves and Utility Levels

Up to this point, we have we have focused exclusively on the characterization of preferences. Let us now consider the other side of the consumer model – the budget constraint. The simplest approach to

characterizing consumer income is to assume that the consumer has a fixed money income which she may spend on any goods. The only constraint on this choice is that the value of the expenditure may not exceed the money income. This is the standard budget constraint:

$$Px + Py = M.$$

Graphically, this equation defines the line depicted in [Figure 3](#). All points inside the budget line are affordable. The consumer faces a choice of which affordable bundle to select.

Figure 3: The Budget Set

Within the framework of our theory, the answer is straightforward – the consumer will choose the one combination of x and y from the set of affordable bundles which maximizes her utility. This combination of x and y will be at the point where the indifference curve is tangent the budget line. This point is called the optimal choice. We see this illustrated in [Figure 4](#).

Figure 4: Utility Maximization on the Budget Set

The standard model of consumer behavior provides a starting point for learning *MPSGE*. This introduction is "hands on" – I will discuss issues as they arise, assuming that you have access to a computer and can invoke the program and read the output file. You may wish to learn the rudiments of *GAMS* syntax before starting out, although you may be able to pick up these ideas as they come, depending on your aptitude for computer languages.

4.49.3.3 Getting Started

1. You need to know how to generate a standard text file. There are several methods for doing this. One approach is to use EDIT, the standard DOS text editor. Another approach favored by many people who have used text processors like WordPerfect or Microsoft Word is to use the word processor as a text editor. A disadvantage of this approach is that you will need to remember to always save the edited file in a text format. A final approach, one which I suggest to graduate students who are interested in numerical modeling, is that you develop facility with a "real" programmer's editor like *Emacs*, *Epsilon* or *Brief*. These editors are far more powerful than the DOS Edit, and they are far better suited to computational work than a word processor.
2. You need to have a copy of *GAMS* with *MPSGE* to run on your computer. There are versions of this program for 386/486/586 PCs as well as for most widely-used workstations (SUN,DEC,HP,IBM,etc.). Copies of the program can be obtained directly from *GAMS* (gams@gams.com), or you may take a copy from someone who already has the program. (Copyright restrictions apply only to *GAMS* license files.) You may copy the *GAMS* programs without the license files and the program will only operate in student/demonstration mode. The student version is perfectly adequate for learning about modeling –in fact, it may be better because it's dimensionality restrictions prevent the novice model builder from adding unnecessary details.
3. You need to install *GAMS* with *MPSGE* on your computer. To do this, follow the standard installation procedure:
 - (a) Make a *GAMS* system directory, e.g.

```
c:\>mkdir gams
```
 - (b) Copy all the files from the GAMS distribution diskette(s) into the GAMS system directory; e.g.

```
c:\>copy a:*. * c:\gams
```
 - (c) Connect to the GAMS system directory and run the GAMS installation program e.g.

```
c:\>cd gams
c:\gams>gamsinst
```

The installation program gives you choices regarding which solver you wish to use for various problem classes. For *MPSGE* models, the key choice is the MCP solver. I recommend that you select *MPSGE* if you have this solver on your computer. It is the most efficient and robust solver currently available for this class of models. (*MPSGE* by Michael Ferris and Steve Dirkse of the University of Wisconsin at Madison.)

You complete the installation by adding the *GAMS* system directory to your DOS environment variable, *MPSGE*. Normally, *MPSGE* is initialized at startup in the file `C:>AUTOEXEC.BAT`. Look for a line which looks like "`PATH C:\DOS`" and modify this to read something like: "`PATH C:\DOS;C:\GAMS`" using a text editor.

4. You should verify that the system is operational. Connect to a working directory (never run models from the *GAMS* system directory!). Then, extract and run one of the library models, e.g.

```

C:\>MKDIR WORK

C:\>CD WORK

C:\WORK>GAMSLIB SCARFMGE

C:\WORK>GAMS SCARFMGE

```

If the *GAMS* system is properly installed, these commands will cause *GAMS* to solve a sequence of models from the *SCARFMGE* sample problem. The output from this process is written to file *SCARFMGE.LST*. If you search for the word "STATUS", you can verify that all the cases are processed.

There are a number of *MPSGE* models included in the *GAMS* library. If you are using a student version of *GAMS*, you will be able to process some but not all of the library models. The student version of the program limits the number of variables in the model to 100. (I believe that *GAMS* imposes other limits on use of the student version, but the variable limitation is the most severe constraint.)

Assuming that you have successfully installed the software, let us now proceed to some examples which illustrate both the computing syntax and the underlying economics.

4.49.3.4 Modeling Consumer Demand

4.49.3.4.1 Example 1: Evaluating a Demand Function Consider a standard consumer choice problem, one which might appear on a midterm examination in intermediate microeconomics:

$$\begin{aligned}
 \max U(x, y) &= \ln(x) + 2 \ln(y) \\
 \text{subject to:} \\
 1x + 2y &= 120
 \end{aligned}$$

where 1 is the exogenous price of x and 2 is the price of y .

This type of problem is solved easily using *GAMS*/MINOS (as a nonlinear program). Strictly speaking, it is not the sort of model for which you would need to use *MPSGE*. At the same time, this can be an instructive example.

The key issue in this example is learning how to represent utility functions. *MPSGE* is "non-algebraic" – so function specification depends on an intuitive understanding of the underlying economic structure.

Consider [Figure 5](#) and focus on a single point, $x = 1, y = 1$. There is an indifference curve through this point, and the marginal rate of substitution (MRS) at this point is simply the slope of this curve. The benchmark MRS does not uniquely determine the underlying preferences.

Figure 5: A Calibrated Benchmark

A utility function is represented in *MPSGE* by the specification of: (i) benchmark demand quantities, (ii) benchmark demand prices (iii) an elasticity of substitution at the benchmark point. Benchmark quantities determine an anchor point for the set of indifference curves. Benchmark prices fix the slope of the indifference curve at that point, and the elasticity describes the curvature of the indifference curve. Speaking formally, elasticities provide a "second order approximation" of the utility function. To understand the importance of the benchmark elasticity of substitution, consider [Figure 6](#). This figure shows three indifference curves all of which share the same benchmark quantities and benchmark prices. They differ only in the elasticities of substitution. The least convex (flattest) curve has the highest elasticity, the most convex curve has the lowest elasticity. (When the elasticity of substitution is 0, the indifference curve is L-shaped with the corner at the benchmark point.)

Figure 6: The Elasticity of Substitution

Let us now consider how the consumer optimization problem can be cast as a general equilibrium model. We do this by adding a single factor of production and two "production" sectors. For concreteness, let the factor of production be called labor with a price P_L . One production function converts one unit of labor into one unit of x , the other sector converts 2 units of labor into one unit of y . Setting the labor endowment equal 120, the market clearance condition for labor reads:

$$1x + 2y = 120$$

which is precisely the budget constraint for the consumer's problem.

We will now present the program code, a few lines at a time. As part of working through the example, the student should type these lines into a file.

A *MPSGE* model specification is always listed between `$ONTEXT` and `$OFFTEXT` statements. The first statement within an *MPSGE* model-description assigns a name to the model. The model name must begin with a letter and must have 10 or fewer characters.

```
$ONTEXT
```

```
$MODEL : DEMAND
```

The model specification begins by declaring variables for the model. In a standard model, there are three types of variables: commodity prices, sectoral activity levels, and consumer incomes. The end of each line may include "! variable description".

N.B. The variables associated with commodities are prices, not quantities. (In this and subsequent models, I use P as the first letter for each of the commodity variables to remind us that these variables are prices.)

N.B. The variable associated with a consumer is an income level, not a welfare index.

```
$SECTORS:
    X      ! ACTIVITY LEVEL FOR X = DEMAND FOR GOOD X
    Y      ! ACTIVITY LEVEL FOR Y = DEMAND FOR GOOD Y

$COMMODITIES:
    PX     ! PRICE OF X WHICH WILL EQUAL PL
    PY     ! PRICE OF Y WHICH WILL EQUAL 2 PL
    PL     ! PRICE OF THE ARTIFICIAL FACTOR L

$CONSUMERS:
    RA     ! REPRESENTATIVE AGENT INCOME
```

Function specifications follow the variable declarations. In this model, our first declarations correspond to the two production sectors. In this model, the production structures are particularly simple. Each of the sectors has one input and one output. In the *MPSGE* syntax, I: denotes an input and O: denotes an output. The output quantity coefficients for both sectors are unity (Q:1). This means that the level values for x and y correspond to the actual quantities produced. The final function specified in the model represents the utility function and endowments for our single consumer. In this function, the E: entries correspond to endowments and the D: entries are demands. Reference demands, reference prices and the substitution elasticity (s:1) characterize preferences.

The demand entries shown here are consistent with a Cobb-Douglas utility function in which the budget share for y is twice the budget share for x (i.e. the MRS at (1,1) equals 1/2):

```
$PROD:X
    O:PX   Q:1
    I:PL   Q:1

$PROD:Y
    O:PY   Q:1
    I:PL   Q:2

$DEMAND:RA  s:1
    E:PL    Q:120
    D:PX    Q:1   P:(1/2)
    D:PY    Q:1   P:1

$OFFTEXT
```

The final three statements in this file invoke the *MPSGE* preprocessor, "generate" and solve the model:

```
$SYSINCLUDE mpsgeset DEMAND

$INCLUDE DEMAND.GEN
SOLVE DEMAND USING MCP;
```

The preprocessor invocation (`$SYSINCLUDE mpsgeset`) should be placed immediately following the `$OFFTEXT` block containing the model description. The model generator code, `DEMAND.GEN`, is produced by the previous statement and must be referenced immediately before each subsequent `SOLVE` statement.

At this point, the reader should take the time to type the example into a file and execute the program with `GAMS/MPSGE`.

This is possibly the first GAMS model which some readers have solved, so it is worth looking through the listing file in some detail. After running the solver, we examine the listing file. I typically begin my assessment of a model's solution by searching for "STATUS". For this model, we have the following:

```

                S O L V E      S U M M A R Y

MODEL   DEMAND
TYPE    MCP
SOLVER  PATH                      FROM LINE  263

**** SOLVER STATUS      1 NORMAL COMPLETION
**** MODEL STATUS      1 OPTIMAL

RESOURCE USAGE, LIMIT      1.432      1000.000
ITERATION COUNT, LIMIT     5          1000
EVALUATION ERRORS          0          0

Work space allocated      --      4.86 Mb

```

Default price normalization using income for RA

This information is largely self-explanatory. The most important items are the `SOLVER STATUS` and `MODEL STATUS` indicators. When the solver status is 1 and the model status is 1, the system has returned an equilibrium.

For small models such as this, the limits on resource usage (time) and solver iterations have no effect. (You can modify these values with the statements:

```

model.RESLIM = number of cpu seconds ;

model.ITERLIM = number of iterations ;

```

entered into the program before the `SOLVE` statement.)

The work space allocation for `MPSGE` models is determined by the number of variables in the model. It is possible to exogenously specify the work space allocation by assigning

```

model.WORKSPACE = xx ;

```

where `xx` is the desired number of megabytes.

The final message, "Default price normalization...", is significant. It reminds the user that an Arrow-Debreu general equilibrium model determines only relative prices. In such an equilibrium, the absolute scaling of prices is indeterminant. (I.e., if (p^*, M^*) are a set of equilibrium prices and income levels, then $(2 p^*, 2 M^*)$ is also a solution, etc.)

It is common practice in economics to address the normalization issue through the specification of a numeraire commodity. You can do this for an `MPSGE` model by "fixing" a price, with a statement like:

PX.FX = 1;

entered following the model declaration (`$SYSINCLUDE mpsgeset`) but prior to the solver invocation. When any price or income level is fixed, *MPSGE* recognizes that a numeraire has been specified and does no automatic normalization.

Following some output from the solver (PATH in this case), the listing file provides a complete report of equilibrium values. With *MPSGE* models, the equation listings are superfluous. The variable listings provide all the relevant information.

For this model, the solution listing appears as follows:

	LOWER	LEVEL	UPPER	MARGINAL
---- VAR X	.	40.000	+INF	.
---- VAR Y	.	40.000	+INF	.
---- VAR PX	.	1.000	+INF	.
---- VAR PY	.	2.000	+INF	.
---- VAR PL	.	1.000	+INF	.
---- VAR RA	.	120.000	+INF	.

X	SUPPLY AND DEMAND OF GOOD X
Y	SUPPLY AND DEMAND OF GOOD Y
PX	PRICE OF X WHICH WILL EQUAL CX * PL
PY	PRICE OF Y WHICH WILL EQUAL CY * PL
PL	PRICE OF THE ARTIFICIAL FACTOR L
RA	REPRESENTATIVE AGENT INCOME

The LOWER and UPPER columns report variable bounds applied in the model. In these columns, zero is represented by "." and infinity is represented by "+INF". The LEVEL column reports the solution value returned by the algorithm. Here we see that the equilibrium price of *x* is 1 and the price of *y* is 2, as determined by the specification of labor inputs.

4.49.3.4.2 Exercises 1 (a) The utility function calibration point is arbitrary. Here, we have selected $x = y = 1$ as the reference quantity. Revise the program to use a different calibration point where $x = 2$ and $y = 1$, where $MRS(2, 1) = 1/4$. (Remember to modify both the *Q* : and *P* : fields.) Rerun the model to demonstrate that this does not change the result.

(b) Increase the price of *x* from 1 to 2 by changing the *Q* : coefficient for *PL* in sector *X* from 1 to 2. What happens to the demand for *x*? Explain why a change in the price of *x* is represented by a change in the *Q* : field for sector *X*.

(c) Compute an equilibrium in which commodity *y* is defined as the numeraire.

4.49.3.4.3 Example 2: Evaluating the MRS This example further explores the representation of demand functions with *MPSGE*. It sets up a trivial equilibrium model with two goods and one consumer which returns the marginal rate of substitution of good *x* for good *y* at a given level of demand. The underlying utility function is:

$$U(x, y) = \ln(x) + 4 \ln(y)$$

When $x = y = 1$, the marginal rate of substitution of *x* for *y* is $1/4$. We use this information to calibrate the demand function, specifying the ratio of the reference prices of *x* to *y* equal to $1/4$.

In an equilibrium, final demand always equals endowments for both goods, because these are the only sources of demand and supply. The model as parameterized demonstrates that if we set endowments for this model equal to the demand function calibration point, the model equilibrium price ratio equals the benchmark MRS.

This program begins with some GAMS statements in which three scalar parameters are declared. These parameters will be used in the place of numbers within the *MPSGE* model. The syntax for these GAMS statements is introduced in Chapter 2 of the *GAMS* manual. In short, we declare x , y and MRS as scalar parameters and initialize the first two of these to unity. The MRS parameter is assigned a value following the solution of the model.

```
SCALAR
    X      QUANTITY OF X FOR WHICH THE MRS IS TO BE EVALUATED /1/
    Y      QUANTITY OF Y FOR WHICH THE MRS IS TO BE EVALUATED /1/
    MRS    COMPUTED MARGINAL RATE OF SUBSTITUTION;
The remainder of the <em>MPSGE</em> program is, in fact, simpler than Example 1.

$ONTEXT

$MODEL:MRSCAL

$COMMODITIES:
    PX      ! PRICE INDEX FOR GOOD X
    PY      ! PRICE INDEX FOR GOOD Y

$CONSUMERS:
    RA      ! REPRESENTATIVE AGENT

$DEMAND:RA  s:1
    D:PX    Q:1    P:(1/4)
    D:PY    Q:1    P:1
    E:PX    Q:X
    E:PY    Q:Y

$OFFTEXT
$SYSINCLUDE mpsgeset MRSCAL

$INCLUDE MRSCAL.GEN
SOLVE MRSCAL USING MCP;
```

Following the solution, we compute a function of the solution values, the ratio of the price of x to the price of y . We do this using the GAMS syntax which references the equilibrium level values of the PX and PY and storing this result in the scalar MRS. This scalar value is then displayed in the listing file with 8 digits:

```
MRS = PX.L / PY.L;
OPTION MRS:8;
DISPLAY MRS;
```

4.49.3.4.4 Exercises 2 (a) Show that the demand function is homothetic by uniform scaling of the x and y endowments. The resulting MRS should remain unchanged.

(b) Modify the demand function calibration point so that the reference prices of both x and y equal unity (hint: the marginal rate of substitution is:

$$MRS = x/(4y).$$

4.49.3.4.5 Example 3: Leisure Demand and Labor Supply This model investigates the labor-leisure decision. A single consumer is endowed with labor which is either supplied to the market or "repurchased" as leisure. The consumer utility function over market goods (x and y) and leisure is Cobb-Douglas:

$$U(x, y, L) = \ln(x) + \ln(y) + \ln(L)$$

Goods x and y may only be purchased using funds obtained from labor sales. This constraint is written:

$$x + y = \text{LPROD LS}$$

where goods x and y both have a price of unity at base year productivity and LPROD is an index of labor productivity. An increase in productivity is equivalent to a proportional decrease in the prices of x and y .

The model declaration is as follows:

```

SCALAR          LPROD  AGGREGATE LABOR PRODUCTIVITY /1/,
                  CX     COST OF X AT BASE YEAR PRODUCTIVITY /1/,
                  CY     COST OF Y AT BASE YEAR PRODUCTIVITY /1/;

$ONTEXT

$DEMAND:RA    s:1
    E:PLS      Q:120
    D:PLS      Q:1      P:1
    D:PX       Q:1      P:1
    D:PY       Q:1      P:1

$OFFTEXT

```

```

$SYSINCLUDE mpsgeset LSUPPLY

$INCLUDE LSUPPLY.GEN
SOLVE LSUPPLY USING MCP;

```

We can use this model to evaluate the wage elasticity of labor supply. In the initial equilibrium (computed in the last statement) the demands for x , y and L all equal 40. A subsequent assignment to `LPROD` (below) increases labor productivity. After computing a new equilibrium, we can use the change in labor supply to determine the wage elasticity of labor supply, an important parameter in labor market studies. It should be emphasized that the elasticity of labor supply should be an input rather than an output of a general equilibrium model – this is a parameter for which econometric estimates can be obtained.

Here is how the programming works. First, we declare some scalar parameters which we will use for reporting, then save the "benchmark" labor supply in `LS0`:

```

SCALAR
    LS0    REFERENCE LEVEL OF LABOR SUPPLY
    ELS    ELASTICITY OF LABOR SUPPLY WRT REAL WAGE;

LS0 = LS.L;

```

Next, we modify the value of scalar `LPROD`, increasing labor productivity by 1%. Because this is a neoclassical model, this change is equivalent to increasing the real wage by 1%. We need to recompute equilibrium prices after having changed the `LPROD` value:

```

LPROD = 1.01;
$INCLUDE LSUPPLY.GEN
SOLVE LSUPPLY USING MCP;

```

We use this solution to compute and report the elasticity of labor supply as the percentage change in the `LS` activity:

```

ELS = 100 * (LS.L - LS0) / LS0;
DISPLAY ELS;

```

As the model is currently constructed, the wage elasticity of labor supply equals zero. This is because the utility function is Cobb-Douglas over goods and leisure, and the consumer's only source of income is labor. As the real wage rises, this increases both the demand for goods (labor supply) and the demand for leisure. These effect exactly balance out and the supply of labor is unchanged.

4.49.3.4.6 Exercises 3 (a) One way in which the labor supply elasticity might differ from zero in a model with Cobb-Douglas final demand is if there were income from some other source. Let the consumer be endowed with good x in addition to labor. What x endowment is consistent with a labor supply elasticity equal to 0.15?

(b) A second way to "calibrate" the labor supply elasticity is to change the utility function. We can do this by changing the `s:1` to `s:SIGMA`, where `SIGMA` is a scalar value representing the benchmark elasticity of substitution between x , y and L in final demand. Modify the program to include `SIGMA` as a scalar, and find the value for `SIGMA` consistent with a labor supply elasticity equal to 0.15.

4.49.3.5 The Pure Exchange Model

Partial equilibrium analysis forms the basis of most economics courses at the undergraduate level. In these models we focus on price, supply and demand for a single commodity. The partial equilibrium approach neglects indirect effects, through which changes in the market for one good may influence the market for another good.

In the previous section, we focused on the choices of a single consumer. In the present section, we will explore the implications of interactions between many consumers with heterogeneous preferences. Furthermore, the analysis will explore the potentially important interaction between market prices and income which are determined jointly in a general equilibrium.

The most widely-used graphical framework for multi-agent exchange equilibrium analysis is the Edgeworth-Bowley box as illustrated in Figure 7. In this diagram we model the following economy:

Figure 7: The Edgeworth-Bowley Box

- Two types of consumers, denoted A and B . We consider A and B to each represent multiple consumers, each with the same endowments and preferences. This assumption is helpful for justifying our assumption of perfectly competitive, price-taking behavior.
- Two commodities, denoted x and y
- Fixed endowments of both goods. The horizontal axis measures the total world endowment of good X . The vertical axis measure the total world endowment of good Y . Any point in the box then represents an allocation of goods between the two agents. The agent H allocation is measured with respect to the lower left origin. The agent F allocation is measured with respect to the upper right origin.

Each agent has a given initial endowment, here denoted point E . Furthermore, we assume that there is no possibility for trade. The indifference curves through point E therefore represent autarchy welfare levels.

The key idea in this model is that trade can improve both agents' welfare. One agent gives some amount good x to the other in return for an amount of good y . The "terms of trade", the rate of exchange between x and y , is determined by the model. The model illustrates a number of important properties of market economies:

- Trade is mutually beneficial. So long as the transactions are voluntary, neither H nor F will be hurt by engaging in trade.
- Market prices can be used to guide the economy to a Pareto-efficient allocation, a state of affairs in which further mutually-beneficial trades are not possible.
- There is no guarantee that the gains from trade will be "fairly distributed" across consumers. A competitive equilibrium may produce a significant welfare increase for one consumer while have negligible impact on the other.
- There are multiple Pareto-efficient allocations, typically only one of which is a competitive equilibrium. We can use this model to demonstrate that the issues of efficiency and equity can be separated when there is the possibility of lump-sum income transfers between agents.

4.49.3.6 Modeling Pure Exchange with MPSGE

4.49.3.6.1 Example 4: A 2x2 Exchange Model In this program, we examine the simple two good, two agent model of exchange equilibrium. The world endowments for goods x and y are both equal to 1. Six parameters are used to parameterize the model. These are declared as scalars at the top of the program:

```
SCALAR  XA          AGENT A ENDOWMENT OF X ( 0 < XA < 1)    /0.2/
        YA          AGENT A ENDOWMENT OF Y ( 0 < YA < 1)    /0.8/
        THETA_A     AGENT A DEMAND SHARE PARAMETER FOR X     /0.5/
        THETA_B     AGENT B DEMAND SHARE PARAMETER FOR X     /0.8/
        SIGMA_A     AGENT A ELASTICITY PARAMETER              /2.0/
        SIGMA_B     AGENT B ELASTICITY PARAMETER              /0.5/;
```

This model is actually simpler than the models presented above because we have no need for production. There are simply two commodities and two consumers. The consumers differ in terms of commodity endowments and preferences. The competitive equilibrium prices are such that supply equals demand for both goods and both agents spend an amount equal to their endowment income.

This model illustrates how to use computed function coefficients. See, for example, $Q:(1-THETA\_A)$ in the $\$DEMAND:A$ block. Any numeric input field in an MPSGE model may be "computed", provided that the algebraic expression is enclosed within parentheses and legitimate *GAMS* code.

This model specification uses the default values for reference prices in the demand function blocks. When $P:value$ is not specified in a $D:,I:$ or $O:$ record, $P:1$ is assumed.

This model uses the more general constant-elasticity-of-substitution utility function.

    IRATIO  EQUILIBRIUM RATIO OF CONSUMER A INCOME TO CONSUMER B INCOME;

PRATIO = PX.L / PY.L;
IRATIO = A.L / B.L;

DISPLAY IRATIO, PRATIO;

```

The foregoing sets up the model and computes the competitive equilibrium. After *GAMS* returns from the solver, we declare and compute some report values.

Absolute levels of income and price returned from a general equilibrium model are not meaningful because a model determines only relative prices. For this reason, we report equilibrium income and price levels in relative terms.

In the final step, we compute an alternative efficient equilibrium, one in which the income levels for A and B are equal. The purpose of this exercise is to demonstrate the second welfare theorem. When incomes are both fixed, the equilibrium remains efficient, but the connection between market prices and endowment income is eliminated.

In *GAMS/MPSGE*, a variable may be fixed using the *GAMS* syntax

```
variable.fx= value;
```

as illustrated in this model:

```

A.FX = 1;
B.FX = 1;
$INCLUDE EXCHANGE.GEN

SCALAR      TRANSFER  IMPLIED TRANSFER FROM A TO B AS A PERCENTAGE OF INCOME;

TRANSFER = 100 * ( A.L - PX.L * XA - PY.L * YA ); PRATIO = PX.L / PY.L;
IRATIO = A.L / B.L;

DISPLAY TRANSFER, PRATIO, IRATIO;

```

4.49.3.6.2 Exercises 4 (a) Set up a separate models which computes the autarchy price ratios for consumers A and B. (You can use one of the earlier models as a starting point.)

(b) Determine parameter values for which the endowment point is the equilibrium point.

(c) Set up a series of computations from which you can sketch the efficiency locus. Draw the Edgeworth box diagram which is consistent with these values.

4.49.3.6.3 Example 5: Import Tariffs and Market Power The exchange model provides a remarkably useful tool for analyzing issues related to international trade. Formal trade theory is more complicated with the inclusion of separate production technologies. We will present some of those models below. Before going forward, however, we will consider a slight generalization of the 2x2 model exchange model. In this extension, we introduce independent markets for consumers A and B and trade activities which deliver goods from one market to the other.

The set of input parameters largely the same as in the previous example. Two new parameters are ad-valorem tariffs which apply on imports to each of the regions.

```
SCALAR  XA          AGENT A ENDOWMENT OF X ( 0 le XA le 1)    /0.2/
        YA          AGENT A ENDOWMENT OF Y ( 0 le YA le 1)    /0.8/
        THETA_A     AGENT A DEMAND SHARE PARAMETER FOR X      /0.4/
        THETA_B     AGENT B DEMAND SHARE PARAMETER FOR X      /0.6/
        SIGMA_A     AGENT A ELASTICITY PARAMETER              /1.0/
        SIGMA_B     AGENT B ELASTICITY PARAMETER              /1.0/,
        T_A         AD-VALOREM TARIFF ON IMPORTS TO AGENT A /0.10/
        T_B         AD-VALOREM TARIFF ON IMPORTS TO AGENT B /0.10/;
```

The program differs from the previous example in several respects. First, we introduce a separate commodity price for each agent. In the absence of tariffs, these prices are identical.

A second difference is that in this model trade activities deliver goods from one agent to the other. These are denoted $M\{\text{good}\}\{\text{agent}\}$ for imports of $\{\text{good}\}$ to $\{\text{agent}\}$. There are four flows which may be operated in only one direction (the activity levels are non-negative). In terms of initial endowments and preferences, this model has exactly the same economic structure as the previous model.

      D:PY B  Q:(1-THETA_B)

```

The trade activities each have one input and one output. They simply deliver a good (X or Y) from one agent to the other. The new syntax presented here is specification of an ad-valorem tax. Adding a tax requires two new fields. The first is "A:" which specifies the tax agent, a consumer who collects the tax revenue as part of income. The second is "T:" which specifies the ad- valorem tax rate.

MPSGE permits taxes to applied on production inputs and outputs but it does not permit taxes on final demand.

The tax applies on a net basis on inputs. For example, if we consider the MXA sector, the price of one unit of input is given by:

$$Px_B * (1 + Ta)$$

where Px_B is the net of tax price of a unit of x in the agent B market and Ta is the ad-valorem tariff rate.

```

The final portions of the file introduces one use of "MPSGE report variables". In this case, report variables are used to recover a Hicksian money-metric welfare index for each of the agents. We compute the initial, tariff-ridden equilibrium in order to compute the benchmark welfare levels. We then set all tariffs to zero and compute the free-trade equilibrium. Using the final welfare indices and the saved values of the benchmark welfare levels, we are able to report the change in welfare from removing tariff distortions.

4.49.3.6.4 Exercises 5 (a) Find the "optimal tariff" in this model for agent A, assuming that agent B does not retaliate and leaves her tariff rate at the benchmark level.

(b) Insert the endowment and preference parameters from the previous problem, retaining the same "benchmark" tariff rates. Does free trade benefit both countries? If not, why not?

4.49.4 Constant Elasticity of Substitution Functions: Some Hints and Useful Formulae

Notes prepared for GAMS General Equilibrium Workshop held December, 1995 in Boulder Colorado

Thomas F. Rutherford, Department of Economics, University of Colorado

December, 1995 :

4.49.4.1 The Basics

In many economic textbooks the constant elasticity of substitution (CES) utility function is defined as:

$$U(x, y) = (\alpha x^\rho + (1 - \alpha)y^\rho)^{\frac{1}{\rho}},$$

It is a fairly routine but tedious calculus exercise to demonstrate that the associated demand functions are:

$$x(p_x, p_y, M) = \left(\frac{\alpha}{p_x} \right)^\sigma = \frac{M}{\alpha^\sigma p_x^{1-\sigma} + (1-\alpha)^\sigma p_y^{1-\sigma}},$$

and

$$y(p_x, p_y, M) = \left(\frac{1-\alpha}{p_y} \right)^\sigma = \frac{M}{\alpha^\sigma p_x^{1-\sigma} + (1-\alpha)^\sigma p_y^{1-\sigma}},$$

The corresponding indirect utility function has is:

$$V(p_x, p_y, M) = M \left(\alpha^\sigma p_x^{1-\sigma} + (1-\alpha)^\sigma p_y^{1-\sigma} \right)^{\frac{1}{\sigma-1}},$$

Note that $U(x,y)$ is linearly homogeneous:

$$U(\lambda x, \lambda y) = \lambda U(x, y)$$

This is a convenient cardinalization of utility, because percentage changes in U are equivalent to percentage Hicksian equivalent variations in income.

Because U is linearly homogeneous, V is homogeneous of degree one in M and degree -1 in p .

In the representation of technology, we have an analogous set of relationships, based on the cost and compensated demand functions. If we have a CES production function of the form:

$$y(K, L) = \gamma (\alpha K^\rho + (1-\alpha)L^\rho)^{\frac{1}{\rho}},$$

the unit cost function then has the form:

$$c(p_K, p_L) = \left(\frac{1}{\gamma} \right) \left(\alpha^\sigma p_K^{1-\sigma} + (1-\alpha)^\sigma p_L^{1-\sigma} \right)^{\frac{1}{1-\sigma}},$$

and associated demand functions are:

$$K(p_K, p_L) = \left(\frac{y}{\gamma} \right) \left(\frac{\alpha \gamma c(p_K, p_L)}{p_K} \right)^\sigma,$$

and

$$L(p_K, p_L) = \left(\frac{y}{\gamma} \right) \left(\frac{(1-\alpha) \gamma c(p_K, p_L)}{p_L} \right)^\sigma.$$

In most large-scale applied general equilibrium models, we have many function parameters to specify with relatively few observations. The conventional approach is to *calibrate* functional parameters to a single benchmark equilibrium. For example, if we have benchmark estimates for output, labor, capital inputs and factor prices, we calibrate function coefficients by inverting the factor demand functions:

$$\theta = \frac{\bar{p}_K \bar{K}}{\bar{p}_K \bar{K} + \bar{p}_L \bar{L}}, \quad \rho = \frac{\sigma-1}{\sigma}, \quad \alpha = \theta \bar{K}^{\frac{-1}{\rho}},$$

and

$$\gamma = \bar{y} [\alpha \bar{K}^\rho + (1-\alpha) \bar{L}^\rho]^{\frac{-1}{\rho}}.$$

4.49.4.2 The Calibrated Share Form

Calibration formulae for CES functions are messy and difficult to remember. Consequently, the specification of function coefficients is complicated and error-prone. For applied work using calibrated functions, it is much easier to use the "calibrated share form" of the CES function. In the calibrated form, the cost and demand functions explicitly incorporate

- benchmark factor demands
- benchmark factor prices
- the elasticity of substitution
- benchmark cost
- benchmark output
- benchmark value shares

In this form, the production function is written:

$$y = \bar{y} \left[\theta \left(\frac{K}{\bar{K}} \right)^\rho + (1 - \theta) \left(\frac{L}{\bar{L}} \right)^\rho \right]^{\frac{1}{\rho}}$$

The only calibrated parameter, θ , represents the value share of capital at the benchmark point. The corresponding cost functions in the calibrated form is written:

$$c(p_K, p_L) = \bar{c} \left[\theta \left(\frac{p_K}{\bar{p}_K} \right)^{1-\sigma} + (1 - \theta) \left(\frac{p_L}{\bar{p}_L} \right)^{1-\sigma} \right]^{\frac{1}{1-\sigma}}$$

where $\bar{c} = \bar{p}_L \bar{L} + \bar{p}_K \bar{K}$ and the compensated demand functions are:

$$K(p_K, p_L, y) = \bar{K} \frac{y}{\bar{y}} \left(\frac{\bar{p}_K}{p_K} \frac{c}{\bar{c}} \right)^\sigma$$

and

$$L(p_K, p_L, y) = \bar{L} \frac{y}{\bar{y}} \left(\frac{c}{\bar{c}} \frac{\bar{p}_L}{p_L} \right)^\sigma.$$

Normalizing the benchmark utility index to unity, the utility function in calibrated share form is written:

$$U(x, y) = \left[\theta \left(\frac{x}{\bar{x}} \right)^\rho + (1 - \theta) \left(\frac{y}{\bar{y}} \right)^\rho \right]^{\frac{1}{\rho}}$$

Defining the unit expenditure function as:

$$e(p_x, p_y) = \left[\theta \left(\frac{p_x}{\bar{p}_x} \right)^{1-\sigma} + (1 - \theta) \left(\frac{p_y}{\bar{p}_y} \right)^{1-\sigma} \right]^{\frac{1}{1-\sigma}}$$

the indirect utility function is:

$$V(p_x, p_y, M) = \frac{M}{\bar{M} e(p_x, p_y)}$$

and the demand functions are:

$$x(p_x, p_y, M) = \bar{x} V(p_x, p_y, M) \left(\frac{e(p_x, p_y) \bar{p}_x}{p_x} \right)^\sigma$$

and

$$y(p_x, p_y, M) = \bar{y} V(p_x, p_y, M) \left(\frac{e(p_x, p_y) \bar{p}_y}{p_y} \right)^\sigma$$

The calibrated form extends directly to the n-factor case. An n-factor production function is written:

$$y = f(x) = \bar{y} \left[\sum_i \theta_i \left(\frac{x_i}{\bar{x}_i} \right)^\rho \right]^{\frac{1}{\rho}}$$

and has unit cost function:

$$C(p) = \bar{C} \left[\sum_i \theta_i \left(\frac{p_i}{\bar{p}_i} \right)^{1-\sigma} \right]^{\frac{1}{1-\sigma}}$$

and compensated factor demands:

$$x_i = \bar{x}_i \frac{y}{\bar{y}} \left(\frac{C \bar{p}_i}{C p_i} \right)^\sigma$$

4.49.4.3 Exercises

(i) Show that given a generic CES utility function:

$$U(x, y) = (\alpha^\rho + (1 - \alpha)y^\rho)^{\frac{1}{\rho}}$$

can be represented in share form using:

$$\bar{x} = 1, \bar{y} = 1, \bar{p}_x = t\alpha, \bar{p}_y = t(1 - \alpha), \bar{M} = t.$$

for any value of $t > 0$.

(ii) Consider the utility function defined:

$$U(x, y) = (x - a)^\alpha (y - b)^{1-\alpha}$$

A benchmark demand point with both prices equal and demand for y equal to twice the demand for x . Find values for which are consistent with optimal choice at the benchmark. Select these parameters so that the income elasticity of demand for x at the benchmark point equals 1.1.

(iii) Consider the utility function:

$$U(x, L) = (\alpha L^\rho + (1 - \alpha)x^\rho)^{\frac{1}{\rho}}$$

which is maximized subject to the budget constraint:

$$p_x x = M + \omega(\bar{L} - L)$$

in which M is interpreted as non-wage income, ω is the market wage rate. Assume a benchmark equilibrium in which prices for x and L are equal, demands for x and L are equal, and non-wage income equals one-half of expenditure on x . Find values of α and ρ consistent with these choices and for which the price elasticity of labor supply equals 0.2.

(iv) Consider a consumer with CES preferences over two goods. A price change makes the benchmark consumption bundle unaffordable, yet the consumer is indifferent. Graph the choice. Find an equation which determines the elasticity of substitution as a function of the benchmark value shares. (You can write down the equation, but it cannot be solved in closed form.)

(v) Consider a model with three commodities, x , y , and z . Preferences are CES. Benchmark demands and prices are equal for all goods. Find demands for x , y and z for a doubling in the price of x as a function of the elasticity of substitution.

(iv) Consider the same model in the immediately preceding question, except assume that preferences are instead given by:

$$U(x, y, z) = (\beta \min(x, y)^\rho + (1 - \beta)z^\rho)^{\frac{1}{\rho}}$$

Determine β from the benchmark, and find demands for x , y and z if the price of x doubles.

4.49.4.4 Flexibility and Non-Separable CES functions

We let π_i denote the user price of the i th input, and let $x_i(\pi)$ be the cost-minimizing demand for the i th input. The reference price and quantities are $\bar{\pi}_i$ and $\bar{x}_i$. One can think of set i as $\{K, L, E, M\}$ but the methods we employ may be applied to any number of inputs. Define the reference cost, and reference value share for i th input by $\bar{C}$ and θ_i , where

$$\bar{C} \equiv \sum_i \bar{\pi}_i \bar{x}_i$$

and

$$\theta_i \equiv \frac{\pi_i \bar{x}_i}{\bar{C}}.$$

The single-level constant elasticity of substitution cost function in "calibrated share form" is written:

$$C(\pi) = \bar{C} \left(\sum_i \theta_i \left(\frac{\pi_i}{\bar{\pi}_i} \right)^{1-\sigma} \right)^{\frac{1}{1-\sigma}}$$

Compensated demands may be obtained from Shephard's lemma:

$$x_i(\pi) = \frac{\delta C}{\delta \pi_i} \equiv C_i = \bar{x}_i \left(\frac{C(\pi)}{\bar{C}} \frac{\bar{\pi}_i}{\pi_i} \right)^\sigma$$

Cross-price Allen-Uzawa elasticities of substitution (AUES) are defined as:

$$\sigma_{ij} \equiv \frac{C_{ij}C}{C_i C_j}$$

where

$$C_{ij} = \frac{\delta^2 C(\pi)}{\delta \pi_i \delta \pi_j} = \frac{\delta x_i}{\delta \pi_j} = \frac{\delta x_j}{\delta \pi_i}$$

For single-level CES functions:

$$\sigma_{ij} = \sigma \quad \forall_{i \neq j} \quad .$$

The CES cost function exhibits homogeneity of degree one, hence Euler's condition applies to the second derivatives of the cost function (the Slutsky matrix):

$$\sum_j C_{ij}(\pi)(\pi_j) = 0$$

or, equivalently:

$$\sum_j \sigma_{ij}(\theta_j) = 0$$

The Euler condition provides a simple formula for the diagonal AUES values:

$$\sigma_{ii} = \frac{-\sum_{j \neq i} \sigma_{ij} \theta_j}{\theta_i}$$

As an aside, note that convexity of the cost function implies that all minors of order 1 are negative, i.e. $\sigma_{ii} < 0 \quad \forall_i$. Hence, there must be at least one positive off-diagonal element in each row of the AUES or Slutsky matrices. When there are only two factors, then the off-diagonals must be negative. When there are three factors, then only one pair of negative goods may be complements.

Let:

k be the reference the index of second-level nest

s_{ik} denote the fraction of good i inputs assigned to the k th nest

ω_k denote the benchmark value share of total cost which enters through the k th nest

γ denote the top-level elasticity of substitution

σ^k denote the elasticity of substitution in the k th aggregate

$p_k(\pi)$ denote the price index associated with aggregate k , normalized to equal unity in the benchmark, i.e.:

$$p_k(\pi) = \left[\frac{\sum_i s_{ik} \theta_i}{\omega_k \left(\frac{\pi_i}{\Pi_i} \right)^{1-\sigma^k}} \right]^{\frac{1}{1-\sigma^k}}$$

The two-level nested, nonseparable constant-elasticity-of-substitution (NNCES) cost function is then defined as:

$$C(\pi) = \bar{C} \left(\sum_k \omega_k p_k(\pi)^{1-\gamma} \right)^{\frac{1}{1-\gamma}}$$

Demand indices for second-level aggregates are needed to express demand functions in a compact form. Let $z_k(\pi)$ denote the demand index for aggregate k , normalized to unity in the benchmark; i.e.

$$z_k(\pi) = \left(\frac{C(\pi)}{\bar{C}} \frac{1}{p_k(\pi)} \right)^\gamma$$

Compensated demand functions are obtained by differentiating $C(\pi)$. In this derivative, one term arise for each nest in which the commodity enters, so:

$$x_i(\pi) = \bar{x}_i \sum_K z_k(\pi) \left(\frac{p_k(\pi) \bar{\pi}_i}{\pi_i} \right)^{\sigma^k} = \bar{x}_i \sum_k \left(\frac{C(\pi)}{\bar{C}} \frac{1}{p_k(\pi)} \right)^\gamma \left(\frac{p_k(\pi) \bar{\pi}_i}{\pi_i} \right)^{\sigma^k}$$

Simple differentiation shows that benchmark cross-elasticities of substitution have the form:

$$\sigma_{ij} = \gamma + \sum_k \frac{(\sigma^k - \gamma) s_{ik} s_{jk}}{\omega_k}$$

Given the benchmark value shares θ_i and the benchmark cross-price elasticities of substitution, σ_{ij} , we can solve for values of s_{ik} , ω_k , σ^k and γ . We compute these parameters using a constrained nonlinear programming algorithm, CONOPT, which is available through GAMS, the same programming environment in which the equilibrium model is specified. Perroni and Rutherford (EER, 1994) prove that calibration of the NNCES form is possible for arbitrary dimensions whenever the given Slutsky matrix is negative semi-definite. The two-level (NxN) function is flexible for three inputs; and although we have not proven that it is flexible for 4 inputs, the only difficulties we have encountered have resulted from indefinite calibration data points.

Two GAMS programs are listed below. The first illustrates two analytic calibrations of the three-factor cost function. The second illustrates the use of numerical methods to calibrate a four-factor cost function.

4.49.4.8 Calibrating Labor Supply and Savings Demand

This material was published in the MUG newsletter, 8/95.

Following Ballard, Fullerton, Shoven and Whalley (BFSW), we consider a representative agent whose utility is based upon current consumption, future consumption and current leisure. Changes in "future consumption" in this static framework are associated with changes in the level of savings. There are three prices which jointly determine the price index for future consumption. These are:

P_I the composite price index for investment goods

P_K the composite rental price for capital services

P_C the composite price of current consumption.

All of these prices equal unity in the benchmark equilibrium.

Capital income in each future year finances future consumption, which is expected to cost the same as in the current period, PC (static expectations). The consumer demand for savings therefore depends not only on P_I , but also on P_K and P_C , namely:

$$P_S = \frac{P_I P_C}{P_K}$$

The price index for savings is unity in the benchmark period. In a counter-factual equilibrium, however, we would expect generally that $P_S \neq P_I$. When these price indices are not equal, there is a "virtual tax payment" associated with savings demand.

Following BFSW, we adopt a nested constant-elasticity-of-substitution function to represent preferences. In this function, at the top level demand for savings (future consumption) trades off with a second CES aggregate of leisure and current consumption. These preferences can be summarized with the following expenditure function:

$$P_U = [\alpha P_H^{1-\sigma_S} + (1-\alpha)P_H^{1-\sigma_S}]^{\frac{1}{1-\sigma_S}}$$

Preferences are homothetic, so we have defined P_U as a linearly homogeneous cost index for a unit of utility. We conveniently scale this price index to equal unity in the benchmark. In this definition, α is the benchmark value share for current consumption (goods and leisure). P_H is a composite price for current consumption defined as:

$$P_H = [\beta P_L^{1-\sigma_L} + (1-\beta)P_C^{1-\sigma_L}]^{\frac{1}{1-\sigma_L}}$$

in which β is the benchmark value share for leisure within current consumption. Demand functions can be written as follows:

$$S = S_0 \left(\frac{P_U}{P_F} \right)^{\sigma_S} \frac{I}{I_0 P_U},$$

$$C = C_0 \left(\frac{P_H}{P_C} \right)^{\sigma_L} \left(\frac{P_U}{P_H} \right)^{\sigma_S} \frac{I}{I_0 P_U},$$

and

$$\ell = \ell_0 \left(\frac{P_H}{P_L} \right)^{\sigma_L} \left(\frac{P_U}{P_H} \right)^{\sigma_S} \frac{I}{I_0 P_U},$$

Demands are written here in terms of their benchmark values (S_0 , C_0 and ℓ_0) and current and benchmark income (I and I_0).

There are four components in income. The first is the value of labor endowment (E), defined inclusive of leisure. The second is the value of capital endowment (K). The third is all other income (M). The fourth is the value of "virtual tax revenue" associated with differences between the shadow price of savings and the cost of investment.

$$I = P_L E + P_K K + M + (P_S - P_I)S$$

The following parameter values are specified exogenously:

1. $\zeta = 1.75$ is the ratio of labor endowment:

$$\zeta \equiv E/L_0$$

where L_0 is the benchmark labor supply. Given ζ and L_0 we have:

$$\ell_0 = L_0(\zeta - 1)$$

2. $\xi = 0.15$ is the uncompensated elasticity of labor supply with respect to the net of tax wage, i.e.

$$\xi = \frac{\delta L}{\delta P_L} \frac{P_L}{L} = \frac{\delta(E - \ell)}{\delta P_L} \frac{P_L}{L} = -\frac{\delta \ell}{\delta P_L} \frac{P_L}{L}$$

3. $\eta = 0.4$ is the elasticity of savings with respect to the return to capital:

$$\eta \equiv \frac{\delta S}{\delta P_K} \frac{S}{P_K}$$

Shephard's lemma applied at benchmark prices provides the following identities which are helpful in deriving expressions for η and ξ :

$$\frac{\delta P_U}{\delta P_H} = \alpha, \frac{\delta P_U}{\delta P_S} = 1 - \alpha, \frac{\delta P_H}{\delta P_L} = \beta, \frac{\delta P_H}{\delta P_C} = 1 - \beta,$$

It is then a relatively routine application of the chain rule to show that:

$$\xi = (\zeta - 1) \left[\sigma_L + \beta(\sigma_S - \sigma_L) - \alpha\beta(\sigma_S - 1) - \frac{E}{I_0} \right]$$

and

$$\eta = \sigma_S \alpha + \frac{K}{I_0}$$

The expression for η does not involve σ_L , so we may first solve for σ_S and use this value in determining σ_L :

$$\sigma_S = \frac{\eta - \frac{K}{I_0}}{\alpha}$$

and

$$\alpha_L = \frac{\frac{\xi}{\xi-1} - \sigma_S \beta(1 - \alpha) - \alpha\beta + \frac{E}{I_0}}{1 - \beta}$$

\$OFFTEXT

\$SYSINCLUDE mpsgeset CHKCAL

S.L = S0;

TS = 0;

* VERIFY THE BENCHMARK:

CHKCAL.ITERLIM = 0;

\$INCLUDE CHKCAL.GEN

SOLVE CHKCAL USING MCP;

* CHECK THE LABOR SUPPLY ELASTICITY:

PL.L = 1.001;

CHKCAL.ITERLIM = 0;

\$INCLUDE CHKCAL.GEN

SOLVE CHKCAL USING MCP;

* Compute induced changes in labor supply using the labor market
 * "marginal", PL.M. This marginal returns the net excess supply of
 * labor at the given prices. We started from a balanced benchmark,
 * with no change in labor demand (the iteration limit was zero).
 * Hence, PL.M returns the magnitude of the change in labor supply.
 * We multiply by the benchmark wage (1) and divide by the benchmark
 * labor supply (LS0) to produce a finite difference approximation
 * of the elasticity:

DISPLAY "CALIBRATION CHECK -- THE FOLLOWING VALUES SHOULD BE IDENTICAL:", XI;

XI = (PL.M / 0.001) * (1 / LS0);

DISPLAY XI;

PL.L = 1.0;

* CHECK THE ELASTICITY OF SAVINGS WRT RENTAL RATE OF CAPITAL:

PK.L = 1.001;

PS.L = 1 / 1.001;

TS = 1 / 1.001 - 1;

CHKCAL.ITERLIM = 0;

```
*      Compute elasticity of savings with respect to the rental rate of
*      capital. This requires some recursion in order to account for the
*      effect of changes in savings on effective income. When PK increases,
*      PS declines -- there is an effective "subsidy" for saving, paid from
*      consumer income. In order to obtain a difference approximation for
*      the elasticity of savings response, we need to make sure the virtual
*      tax payments are properly handled. In the MPSGE model, this means
*      that the level value for S must be adjusted so that it exactly equals
*      the savings. We do this recursively:
```

```
SET ITER /IT1*IT5/;
```

```
PS.M = 1;
LOOP(ITER$(ABS(PS.M) GT 1.0E-8),
```

```
$INCLUDE CHKCAL.GEN
      SOLVE CHKCAL USING MCP;
      S.L = S.L - PS.M;
);
```

```
DISPLAY "CALIBRATION CHECK -- THE FOLLOWING VALUES SHOULD BE IDENTICAL:", ETA;
ETA = ((S.L - S0) / 0.001) * (1 / S0);
DISPLAY ETA;
```

4.50 Glossary

acronym	A GAMS data type used for storing non-numeric (aka logical or categorical) data. For more details, see section Acronyms .
alias	An alternative name for a set , used to have multiple indices running over a common set. For more information, see section The Alias Statement: Multiple Names for a Set .
algorithm	A sequence of actions to perform in order to solve a problem. GAMS <i>solvers</i> contain algorithm implementations, so the two terms are sometimes used interchangeably.
assignment	The statement used to assign values to an identifier . For a detailed introduction, see section The Assignment Statement .
basic	A column is basic if it is in the basis maintained by the solution method for the problem in question (e.g. by the simplex method for LP). A row is basic if the elementary column associated with its slack variable is basic. For more details, see Mathematical Programming Glossary
binding	An inequality constraint or variable bound is binding when the value of the associated slack is zero, i.e. when it is satisfied as an equality. See also Mathematical Programming Glossary
bounds	Upper and lower limits on the possible values that a column may assume in a feasible solution. May be infinite, i.e. no limit is imposed.

column	An individual decision variable in the model passed to a solver. Also called a single variable in the GAMS listing file. An indexed GAMS variable typically contains many columns.
compilation	The initial phase of GAMS processing, when the program is being checked for syntax and consistency.
compile-time constant	A compile-time constant is a string that will be replaced at compile-time with a fixed value. These constants are usually related to a function, model attribute or option and are used for their mnemonic and descriptive value. See section Compile-Time Constants .
compile-time variable	Special variables that are substituted with their values at compile-time. For further information, see section Compile-Time Variables .
constraint	A relationship between variables that must hold in a feasible solution . A constraint can refer to a single relationship (i.e. a row) or to a collection of rows, such as an equation . For further details, see Mathematical Programming Glossary
continuous	Used to describe functions (in the usual mathematical way) and variables. Roughly speaking, a function is continuous if its graph has no breaks or jumps in it. A continuous variable may assume any value within its bounds, in contrast to binary or integer variables.
controlling sets	See driving sets .
data types	Each symbol or identifier must be declared as one of the available data types, e.g. set , parameter , equation , or model . Note that scalars and tables are not separate data types, but convenient input formats for certain parameters . See also section Data Types and Definitions .
decision variable	A decision variable (aka endogenous variable) represents a decision to be made, e.g. the amount to produce or consume or the unit price to charge. Decision variables are the unknowns of a mathematical programming model. In contrast, exogenous variables or parameters are outside of the decision maker's control. See also the Mathematical Programming Glossary .
declaration	The introduction of an identifier along with the specification of its data type . A declaration may also include the specification of data or initial values, in which case it also acts as a definition . See also section Classification of GAMS Statements .
default	The value used, or the action taken, if the user provides no information.
definition	A statement specifying the content or data associated with a GAMS identifier , e.g. the equations in a model, the algebra of an equation, the elements of a set , or the initial values of a parameter . Definitions are processed during compilation . See also section Classification of GAMS Statements .
direction	The direction of optimization, i.e. maximization or minimization.
discontinuous	A function is discontinuous if it is not continuous . Sometimes, we call a function discontinuous if its derivatives are not continuous, i.e. it is nonsmooth.

discrete	A discrete variable is any variable that is not continuous . For example, binary and integer variables are discrete. For more details, see section Types of Discrete Variables .
dollar control option	Directives or options used to control input or output details associated with the GAMS compiler. They are introduced in chapter Dollar Control Options .
dollar operator	An operator used to indicate and define conditional expressions in assignment statements and equation definitions. For more information, see section The Dollar Condition .
domain checking	A system of checks that ensures that operations and relationships involving sets and domains are logically consistent. For example, referencing <code>pop(t,city)</code> when we have a declaration of <code>pop(city,t)</code> is a logical error that domain checking will catch. For more information, see section Domain Checking .
domain of definition	The set of tuples (i.e. label combinations) for which an indexed equation is defined. When a solve statement is executed, a row of the equation is generated for each member of the domain of definition.
domain restriction condition	The narrowing of the domain of definition with a dollar operator . When used in this way, the dollar operator occurs on the left of the symbol <code>'.'</code> in an equation definition . For more details, see section Dollar Control over the Domain of Definition .
driving set	The set or list of sets that an indexed operation or domain runs or is defined over. Loops, indexed operations like <code>sum</code> , and domains of definition all make use of driving sets.
dynamic set	A set is dynamic if it has been changed with an assignment statement. Dynamic sets cannot be used with lag operations or in domain declarations. For more information, see chapter Dynamic Sets .
echo print	In the output file, the echo print is a listing of the input with added line numbers. Details are given in section The Echo Print of the Input File .
endogenous	Endogenous variables are used in economics, statistics, and other disciplines. In the GAMS context, they are synonymous with variables, i.e. values that change when a solve statement is processed. See also the discussion in section Functions in Equation Definitions .
equation	The GAMS data type used to specify required relationships between activity levels of variables. They are introduced and discussed in detail in chapter Equations .
execution	The second phase of GAMS processing, when GAMS is actually carrying out data transformations or generating a model.
execution statements	Instructions to carry out actions such as data transformations, model solves and report generation. Examples include the assignment statement , the loop statement and the solve statement. For a full list, see section Classification of GAMS Statements .

exogenous	Exogenous variables are used in economics, statistics, and other disciplines. In the GAMS context, they are synonymous with constants, i.e. values that do <i>not</i> change when a solve statement is processed. These are most often parameters but any variable or equation field will be treated exogenously when it appears in an equation. See also the discussion in section Functions in Equation Definitions .
explanatory text	See text .
extended arithmetic	In GAMS, the usual computer arithmetic is extended to include special values (e.g. <code>inf</code>) and the results of operations and functions that use them. For example, <code>6 + inf</code> is <code>inf</code> and <code>min(6, inf)</code> is <code>6</code> . See section Extended Range Arithmetic and Error Handling for details.
external equation	An equation defined in an external module. For example, on Windows systems, external equations are defined by a DLL. See section External Equations for details.
extrinsic function	A function that is imported into a GAMS program from an external function library. Once imported, extrinsic functions can be used in the same way as intrinsic functions like <code>cos</code> and <code>exp</code> . See section Extrinsic Functions for details.
e-format	A convenient text-based (i.e. unsuperscripted) way to represent numbers in scientific notation in which the exponent of the 10 is prefixed by the letter e . For example, one US mile = 1.609344e+03 meters.
feasible	Often used to describe a model (or a subset of constraints within a model) that has at least one feasible solution , but also used to describe a point that satisfies a set of constraints. For more information, see Mathematical Programming Glossary . See also infeasible .
feasible solution	A solution to a model in which all column activity levels are within the bounds and all the constraints are satisfied. For more information, see Mathematical Programming Glossary .
identifier	The name given to a data entity in a GAMS program. Also called a symbol . See section Identifiers for further details.
indexed operation	An operation (e.g. <code>sum</code> or <code>max</code>) that is performed over one or more indices. See also section Indexed Operations .
inequality constraint	A constraint in which the imposed relationship between the columns is not specified with an equality but instead with an inequality (e.g. "greater than or equal to", "less than or equal to"). The GAMS syntax <code>=G=</code> and <code>=L=</code> is used in equation definitions to specify these relationships.
infeasible	Not feasible . Used to describe either a model that has no feasible solution or an intermediate solution or point that is not feasible (although feasible solutions may exist).

initialization	Associating or assigning <i>initial values</i> to an identifier as part of the declaration or definition of the identifier. We typically talk about the initialization of only those identifiers (e.g. sets and parameters) that can be assigned different values later. For identifiers like models and equations , we say they are <i>defined</i> , not <i>initialized</i> .
intrinsic function	Functions that are provided by and part of GAMS, including mathematical , string , logical , time/calendar , and utility functions. Contrast to extrinsic functions .
label	Sets are built up from labels (aka <i>elements</i>). One-dimensional sets are collections of labels, while multi-dimensional sets contain tuples of labels. See section Labels for details.
list	See list format .
list format	GAMS data may be initialized by data in list format, i.e. a list where each tuple of labels in the data is specified in full. Data may also be displayed in list format, in which case each nondefault value is displayed via a fully-specified tuple of labels.
macro	A macro is a fragment of code that has been given a name: whenever the name is used, that name is replaced by the contents of the macro (i.e. the fragment of code). This is useful for defining and automating structured text replacement, e.g. to replace the text MYOBJ(x) with $[\text{sqr}(x) + \text{exp}(x-2)/7]$. See section Macros in GAMS for details.
marginal	Marginal values (aka "dual values", "reduced costs", "shadow prices", or "multipliers") are stored in the ".m" variable attribute or equation attribute . The GAMS sign convention is this: the marginal value represents the amount and direction of change in the objective value given a <i>unit increase</i> in the binding constant (e.g. an active variable bound or right-hand side). For further information, see Mathematical Programming Glossary
matrix element	See nonzero element .
model generation	An initial step in processing a solve statement, where a model instance is generated (based on the equation definitions and the data referenced by those definitions) for the solver.
model list	The list of equations that are part of the model, as specified in the model statement. For further details, see section The Model Statement .
model status	An integer returned by the solver that gives information about the model (e.g. INFEASIBLE), about the point returned by the solver (e.g. LOCALLY INFEASIBLE), or both (UNBOUNDED NO SOLUTION RETURNED). For an overview of all values, see section Model Status .
nonbasic	A column that is not basic and (in nonlinear problems) not superbasic . Typically, nonbasic columns behave or are treated as if they are fixed at a bound. If the solution is feasible , the value of a nonbasic column will equal a finite bound (or zero if there are no finite bounds).

nonlinear nonzero	In a linear programming problem, the nonzero elements of the constraint matrix are constant. In a nonlinear problem, elements of the Jacobian matrix vary where variables appear nonlinearly. These non-constant Jacobian elements are called nonlinear nonzeros.
nonoptimal	Not optimal . A solution is nonoptimal if other solutions exist with better objective values . A variable is nonoptimal if its marginal (aka reduced cost) has the wrong sign. For example, in a minimization, a variable at lower bound having a negative marginal is nonoptimal. In the simplex method, a variable is nonoptimal if it is nonbasic and would improve the objective if it entered the basis.
nonsmooth	A function is nonsmooth if it is not smooth , i.e. if the function itself or its derivatives are not continuous. For example, the absolute value function is nonsmooth because of the kink at the origin: its derivative is not continuous there.
nonzero element	An element or coefficient of a matrix (e.g. the constraint matrix of an LP or the Jacobian matrix of an NLP) that is not zero. Most mathematical programming problems are <i>sparse</i> , i.e. only a small proportion of the elements in the constraint or Jacobian matrix are nonzero.
objective row (or function)	Solver systems often require the specification of a row or (for nonlinear systems) a function whose value will be optimized. A GAMS model, in contrast, is solved by specifying a scalar objective variable to be optimized.
objective value	The current value of the objective row or of the objective variable .
objective variable	The variable to be optimized, as specified in the solve statement.
optimal	A feasible solution in which the objective value is the best possible. For more details, see Mathematical Programming Glossary .
optimality gap	The optimality gap is a metric for the distance (or an upper bound on the distance) between the objective value of the current feasible solution and the optimal objective value. For more information, see Mathematical Programming Glossary . In GAMS, MIP and global solvers terminate when the optimality gap is sufficiently reduced: see the options optCA and optCR for details.
option	A control that allows users to change or influence the behavior or parameters in many different parts of the system. Options in GAMS may be set in three different ways: with model attributes , command line parameters , and option statements . A full list of all options with detailed descriptions is given in section Detailed Descriptions of All Options .
ordered set	A one-dimensional set is ordered if the definition or initialization of the elements in the set corresponds to the order of the labels in the universe . Only sets that are ordered (and static) can be treated as sequences, i.e. used in lags and leads and with <code>Ord</code> -type operations. For more information, see chapter Sets as Sequences: Ordered Sets .
output file	A file, also called the listing file, produced (by default) by the run of a GAMS program. It contains output that describes or logs the run in question. For details see chapter GAMS Output .

parameter	A data type in GAMS used to store (indexed) constant data. For details on parameters, see chapter Data Entry: Parameters, Scalars and Tables .
problem type	A class of models that is characterized or defined by the type of algebra accepted (e.g. linear or nonlinear), the GLOSSARY_variable_type "variable types" allowed (e.g. continuous vs. discrete), and the definition of what it means to solve the model or problem (e.g. optimization vs. MCP). A list of all problem types in GAMS is given in section Classification of Models .
program	A GAMS input file. Typically a program defines a model and solves it, but programs can also work only with data or act as scripts that call other programs.
relational operator	This term may be used in two ways. First, in an equation definition, it describes the type of relationship that the equation specifies. An example is equality, as specified with the symbol <code>=e=</code> . For more information, see Table Equation Types . Second, in a logical expression, a relational operator compares two numerical expressions and returns a logical value. For details see section Logical Conditions: Numerical Relational Operators .
right-hand side	The value of the constant term in a constraint .
row	An individual constraint in the model passed to a solver. Also called a single equation in the GAMS listing file. An indexed GAMS equation typically contains many rows.
scalar	An un-indexed parameter , or the statement used to declare or define this parameter. See also section Scalars .
set	A collection of elements (aka <i>labels</i>) or element tuples. The set statement is used to declare and define a set. Sets are introduced and discussed in detail in chapter Set Definition .
simplex method	An algorithm often used to solve linear programming problems. For more details, see Mathematical Programming Glossary
singleton set	A special set that has at most one element (zero elements are allowed as well). For more information, see section Singleton Sets .
slack	The amount by which an inequality constraint or variable bound is not binding .
slack variable	A non-negative variable introduced to represent the slack in an inequality constraint and to convert the inequality into an equality. For further information, see Mathematical Programming Glossary
smooth	A function that is continuous and whose derivatives are all continuous is smooth. Sometime we consider a function smooth if enough of its derivatives are continuous.
solver	An implementation of an algorithm or algorithms for solving models of a given problem type or types. An example is MINOS and QUADMINOS , which is used to solve both linear and nonlinear programming problems.

solver status	An integer returned by the solver that indicates the solver termination condition, i.e. why the solver stopped. For details, see section Solver Status .
statements	Statements (aka units or sentences) are the fundamental building blocks of GAMS programs: each program is a sequence of statements. Statements are used to declare identifiers, define equations, create loops, and solve models. A full list of GAMS statements is given in section Classification of GAMS Statements .
static set	Used in two slightly different ways: a set is static if it <i>has not</i> changed (i.e. it is not dynamic) or if it <i>cannot</i> change, i.e. it is <i>immutable</i> . Usually, sets are either used in ways that make them immutable (e.g. as domains or with lags and leads) or in ways that make them dynamic (i.e. by assigning to them): in such cases, static is synonymous with immutable.
superbasic	Some algorithms for nonlinear programming make use of superbasic variables that are neither basic (i.e. in the basis) nor nonbasic (i.e. temporarily fixed at a bound). These algorithms often search in the space defined by these superbasic variables. For further information, see Mathematical Programming Glossary
symbol	An identifier .
table	A table statement is often a convenient way to define a parameter having two or more dimensions. For details see section Tables .
text	An optional description associated with an identifier or with an element of a set . For details see section Text .
unique element	A label used to define set membership.
universe	Also called the <i>universal set</i> , it is denoted by the symbol '*' and contains all the labels that have been declared in the program plus any labels used as if they were declared (e.g. <code>link('sink',j) = NO;</code>). If an identifier is declared using the universe, that effectively turns off or limits domain checking for that identifier. For more details, see section The Universal Set: * as Set Identifier .
variable type	Variables are classified or typed based on their default bounds and the values they are allowed to take. This latter classification partitions variables into continuous or discrete . For example, free variables have no default bounds and can take any value between their bounds: they are continuous. In contrast, binary variables can take only the values zero and one. See section Variable Types for details.
zero default	Some GAMS data (e.g. parameters , lower bounds for positive variables) have a default value of zero. These default zero values are not stored. However, unless other values are provided via initialization or assignment , zero will be used when the data value is taken.

Chapter 5

Solver Manuals

A large number of solvers for mathematical programming models have been hooked up to GAMS. The tables below provide a brief description of each solver, the [model types](#) each solver is capable of solving, and the [platforms](#) supported by each solver. For general information on using GAMS solvers, see [Solver Usage](#).

Solver	Vendor	Description
ALPHAECP	Abo University	MINLP solver based on the extended cutting plane (ECP) method
AMPL	GAMS Development Corp	A link to solve GAMS models using solvers within the AMPL modeling system
ANTIGONE 1.1	Princeton University	Deterministic global optimization for MINLP
BARON	The Optimization Firm, LLC	Branch-And-Reduce Optimization Navigator for proven global solutions
BDMLP	GAMS Development Corp	LP and MIP solver that comes with any GAMS system
BENCH	GAMS Development Corp	A utility to facilitate benchmarking of GAMS solvers and solution verification
BONMIN 1.8	COIN-OR Foundation	COIN-OR MINLP solver implementing various branch-and-bound and outer approximation algorithms
CBC 2.10	COIN-OR Foundation	High-performance LP/MIP solver
CONOPT 3	ARKI Consulting and Development	Large scale NLP solver
CONOPT 4	ARKI Consulting and Development	Large scale NLP solver
CONVERT	GAMS Development Corp	Framework for translating models into scalar models of other languages
COUENNE 0.5	COIN-OR Foundation	Deterministic global optimization for (MI)NLP
CPLEX 12.9	IBM ILOG	High-performance LP/MIP solver
DE	GAMS Development Corp	Generates and solves the deterministic equivalent of a stochastic program, included in EMP/SP
DECIS	G. Infanger, Inc.	Large scale stochastic programming solver
DICOPT	EDRC, Carnegie Mellon University	Framework for solving MINLP models

Solver	Vendor	Description
EXAMINER	GAMS Development Corp	A tool for examining solution points and assessing their merit
GAMSCHK	Bruce McCarl	A System for Examining the Structure and Solution Properties of Linear Programming Problems Solved using GAMS
GLOMIQO 2.3	Princeton University	Branch-and-bound global optimization for mixed-integer quadratic models
GUROBI 8.1	Gurobi Optimization	High performance LP/MIP solver
GUSS	GAMS Development Corp	A framework for solving many instances of related models efficiently (Gather-Update-Solver-Scatter)
IPOPT 3.12	COIN-OR Foundation	Interior Point Optimizer for large scale nonlinear programming
JAMS	GAMS Development Corp	Solver to reformulate extended mathematical programs (incl. LogMIP)
KESTREL	NEOS	Framework for using remote NEOS solvers with a local GAMS system
KNITRO 11.1	Artelys	Large scale NLP solver
LGO	Pinter Consulting Services	A global-local nonlinear optimization solver suite
LINDO 12.0	Lindo Systems Inc.	A stochastic solver from Lindo Systems, Inc. Includes an unrestricted version of LINDOGLOBAL
LINDOGLOBAL 12.0	Lindo Systems Inc.	MINLP solver for proven global solutions
LINGO	GAMS Development Corp	A link to solve GAMS models using solvers within the LINGO modeling system
LOCALSOLVER 8.5	Innovation 24	Hybrid neighborhood local search solver
LS	Least Square Solver	A Linear Regression Solver for GAMS
MILES	University of Colorado at Boulder	MCP solver
MINOS	Stanford University	NLP solver
MOSEK 9	MOSEK ApS	Large scale mixed-integer conic programming solver
MSNLP	OptTek Systems and Optimal Methods	Multi-start method for global optimization
NLPEC	GAMS Development Corp	MPEC to NLP translator that uses other GAMS NLP solvers
ODHCPLEX 4	Optimization Direct Inc	ODHeuristic on top of Cplex
OsiCplex	COIN-OR Foundation	Bare-Bone link to CPLEX
OsiGurobi	COIN-OR Foundation	Bare-Bone link to Gurobi
OsiMosek	COIN-OR Foundation	Bare-Bone link to Mosek
OsiXpress	COIN-OR Foundation	Bare-Bone link to Xpress
PATHNLP	University of Wisconsin - Madison	Large scale NLP solver for convex problems
PATH	University of Wisconsin - Madison	Large scale MCP solver
PYOMO	GAMS Development Corp	A link to solve GAMS models using solvers within the PYOMO modeling system

Solver	Vendor	Description
SBB	ARKI Consulting and Development	Branch-and-Bound algorithm for solving MINLP models
SCIP 6.0	Zuse Institute Berlin et.al.	High-performance Constraint Integer Programming solver
SELKIE	University of Wisconsin - Madison	Decomposition and parallel solution for EMP
SNOPT	Stanford University	Large scale SQP based NLP solver
SOLVEENGINE	Satalia	Link to use solvers of the Satalia SolveEngine with a local GAMS system
SOPLEX 4.0	Zuse Institute Berlin	High-performance LP solver
XA	Sunset Software	Large scale LP/MIP solver
XPRESS 33.01	FICO	High performance LP/MIP solver

5.1 Model Types

GAMS is able to formulate models in many different types of problem classes or [model types](#). Typically, a solver will be capable of solving (i.e. will accept as input) more than one model type. The solver/model type matrix shows which solver is capable of which model type:

* deterministic global solver

When choosing a solver, some judgement should be applied when considering the listed model type capabilities for the solver - the same capability "check boxes" does not imply equality in capacity or suitability. For example, take a hypothetical solver WeOpt designed to solve MINLP models. Since the problem class MINLP includes NLP, MIP, and LP as subclasses, solver WeOpt could include these capabilities also. If WeOpt is also a good performer on NLP models, it would include that capability. But if it does not shine at all as a MIP or LP solver, we would choose not to include MIP and LP in the capability list for WeOpt. In such a case one can always solve using a more general model type (e.g. solve an LP model as NLP so WeOpt can be used), but WeOpt will not advertise itself as an LP solver. Since the WeOpt solver does not even recognize MCP or MPEC models, we don't include those capabilities.

There are other differences in solvers that are difficult to quantify or cannot be captured by a capability table like the one shown. For example, for nonconvex NLP or QCP models, one solver could look only for first-order stationary points, another for local solutions, a third for local solutions using a scatter search or similar search heuristic, and a fourth could do a true global search for the global optimum. The relative merits (measured typically by speed alone) of solvers is the subject of considerable benchmarking activity and discussion.

The GAMS sales team can help answer questions you may have about solver capability. We also offer free evaluation licenses to help you decide what solvers are most suitable for your models.

5.2 Supported Platforms

The solver/platform matrix shows which platforms each solver is supported on. In addition, where a vendor has discontinued solver support for a particular platform and we continue to ship the last available supported version, this version number is indicated as well.

	x86 32bit MS Windows	x86 64bit MS Windows	x86 64bit Linux	x86 64bit Mac OS X	Sparc 64bit SOLARIS	IBM Power 64bit AIX

5.3 AlphaECP

Tapio Westerlund (twesterl@abo.fi) and Toni Lastusilta. Åbo Akademi University, Finland

5.3.1 Introduction

AlphaECP is a Mixed-Integer Non-Linear Programming (MINLP) solver based on the extended cutting plane (ECP) method. The solver can be applied to general MINLP problems and it can ensure global optimal solutions for pseudo-convex MINLP problems.

The ECP method is an extension of Kelley's cutting plane method, which was originally given for convex NLP problems [139]. The method only requires the solution of a MIP sub-problem in each iteration. The MIP sub-problems can be solved to optimality, to feasibility, or only to an integer relaxed solution in intermediate iterations. This makes the ECP algorithm efficient and easy to implement. Further information about the underlying algorithm can be found in [253] and [192] [226] [252] [254].

Further developments of the GAMS/AlphaECP algorithm have introduced additional functionality. A NLP solver can now be called at MIP solutions. This improves AlphaECP's ability to find feasible and accurate solutions, especially for MINLP problems which mainly contain continuous variables. Furthermore, a heuristic that reselects cutting planes during the iteration procedure can be used to improve the capability of solving non-convex problems.

5.3.1.1 Licensing and software requirements

Users need to have a GAMS/AlphaECP license in order to use GAMS/AlphaECP. In addition, a licensed MIP solver is required for solving the mixed integer sub-problem, and a licensed NLP solver is required if the NLP option is used.

5.3.1.2 Running AlphaECP

AlphaECP solves MINLP models. If AlphaECP is not specified as the default solver for these models it can be invoked by issuing the following command before the solve statement:

```
option minlp=alphaecp, miqcp=alphaecp;
```

In principle AlphaECP can also handle NLP models, but it is more suitable for MINLP problems. However, when combined with an NLP solver it can find solutions the NLP solver cannot find by itself. In this case it acts as a good starting point generator. If you want to solve NLPs with AlphaECP you need to *trick* the GAMS system by solving your NLP as an MINLP:

```
solve mynlpmodel minimizing obj using minlp;
```

Constraint violations are reported throughout the progress of AlphaECP and at the end of the algorithm. The violation is reported for the non-linear constraints only. The violation of the linear constraints is subject to the feasibility tolerance of the MIP/NLP solver.

5.3.2 GAMS/AlphaECP Output

The log output below is obtained for the MINLP model fuel.gms from the GAMS model library:

```

-----
Welcome to Alpha-ECP v2.10.06
MINLP Problem Solver using the Extended Cutting Plane Approach.
Method development - T.Westerlund, Abo Akademi University, FIN
Algorithm implementation - T.Lastusilta, Abo Akademi University, FIN
Westerlund Tapio and Poern Ray (2002). Optimization & Engineering, 3, 253-280
-----

Minimization problem: "fuel.gms"
The GAMS-model has in total 39 elements of which 15% are non-linear(NL)
included in 16 constraints of which 25% are NL
The NL constraint signs: =E=(3), =G=(1), =L=(0)
The number of variables in NL elements are 6 from a total of 16
variables: Continuous(13), Binary(3), Integer(0)
-----

```

In every iteration, information about the MIP problem and modifications to it is given in 10 columns. Here is a description of the different columns:

Iteration: Iteration identifier.

Stepcode, Problems: Letter for what actions were taken in this iteration, i.e. MIP problem modifications before the next iteration.

A: MIP solver feasible.

B: MIP solver feasible after moving cutting planes, i.e. alpha update.

C: MIP solver feasible after moving cutting planes close to their generation point. The movement is done to make it easier to satisfy nonlinear equality constraints.

D: Line search was successful (in [ECPstrategy 3](#)).

E: Line search failed (in [ECPstrategy 3](#)).

F: A NLP solver was called.

G: Found a MINLP solution.

H: Added linearization(s) to the next MIP problem.

I: Updated alpha values and possibly added linearizations.

J: All cutting planes are valid underestimators for the pseudo-convex constraints, except for the nonlinear objective function constraint.

K: The nonlinear objective function constraint value and MIP solution value differ more than ϵ_f . A linearization was done to reduce the difference (in [ECPstrategy 3](#)).

L: Removed all temporal linearizations.

M: Domain violation(s), some of the constraint could not be evaluated.

N: Some cutting plane(s) could not be generated because of gradient problems.

O: No cutting planes could be generated.

P: Reselecting cuts because cutting planes are repeatedly moved close to their generation point.

Q: Added temporal linearization(s).

R: Failed to add temporal linearization(s).

S: MIP solver strategy to find encountered solutions selected.

T: MIP solver strategy to require [MIPnrsols](#) solutions selected.

U: MIP solver strategy to require [MIPnrsols](#) solutions with a [MIPoptcr](#) ≤ 0.2 selected.

Number of Cuts: The number of cutting planes the solved MIP problem had.

Point usage: Number of points used to generate the cuts in the solved MIP problem.

Alpha Upd.: The number of times the alpha values has been increased.

OPTCR: Requirement of the relative distance to the relaxed MIP solution for the current MIP solution.

Movement Norm: The Euclidean norm of the current and previous MIP solution.

Viol Cons: Number of unsatisfied (violating) nonlinear constraints.

Maximum Violation: The most violating nonlinear constraint value.

MIPobjval/NLobjval: MIP or nonlinear objective variable value depending on [ECPstrategy](#) setting.

The cut reselection heuristic is called in the following cases:

1. If the MIP solver would otherwise return infeasible.
2. When the violation is not reducing, but the cutting planes are repeatedly moved close to their generation point.
3. When the violation is not reducing and domain violations are repeatedly encountered.

The heuristic reselects cutting planes in different ways, but always ensures that the same point cannot be found twice.

Pointusage 6/90 Cutusage 15/341 (0,135)

Pointusage informs how many points of all usable points have been used to generate the cutting planes. **Cutusage** tells how many cuts of all usable cuts have been used. The first number in (0,135) tells how many cuts is required by the user, see [CUTnrcuts](#) and the second number gives the sum of added and removed cuts, i.e. a measure of how much the MIP problem has been modified. AlphaECP may fix some cuts and remove points and cuts during the cut reselection procedure in order to save memory.

At the end of each solve AlphaECP gives a summary which includes Problem, Solver Status, Model Status, etc. Note the following lines:

- **Exit comment** may give further information than solverstatus on why the solution procedure stopped.
- **Domain violations** (function evaluation failed) or **Gradients unusable** (all gradients < [TOLgrad](#)) might be caused by poor variable bounds.
- **Alphamax bound violations** inform the user how many times an alphamax value was calculated to be > 10^{154} and was reset to 10^{154} .

5.3.3 Notes about Options

To instruct AlphaECP to read an option file you may use **ModelName.OptFile = 1**. The name of the option file is in this case **alphaecp.opt**. For further information, see [The Solver Options File](#). AlphaECP supports the GAMS parameter [reslim](#), however, other GAMS parameters are passed on to the sub-solvers. Furthermore, you may also pass additional sub-solver specific options to the sub-solvers. For example, if you want to use all available threads and sub-solver CPLEX in opportunistic parallel search mode, then you may specify this in a GAMS model, in a similar way, as follows:

```
Model m / all /;
Option threads=0;
m.optfile=1;
$echo MIPSolver cplex.1 > alphaecp.opt
$echo parallelmode -1 > cplex.opt
Solve m using MINLP minimizing objvar;
```

The following information is worth noting when you are interested in AlphaECP options. A linearization of a nonlinear constraint is called a cutting plane or cut. Here a point refers to the variable levels. Global optimality can be guaranteed for pseudo-convex problems. However, if the objective variable is in a nonlinear constraint and pseudo-convex, then [ECPstrategy](#) >= 3 needs to be used to guarantee global optimality (because one non-linear equality constraint makes a problem non-pseudo-convex, and hence also non-convex). The basic options might significantly impact the solution procedure, and the best values are likely to be problem specific. The user is therefore encouraged to try different values for the basic options.

5.3.4 Summary of AlphaECP Options

5.3.4.1 Basic options

Option	Description	Default
CUTnrcuts	Cut generation pace	0
ECPmaster	Master strategy (0=User 1=Convex)	0
MIPnrsols	Upper limit of considered MIP solutions per MIP call	50
MIPsolstrat	MIP solution collection strategy	1
MIPsolver	MIP solver for sub-problems and . option file number	GAMS MIP solver
NLPsolver	NLP solver for sub-problems and . option file number	GAMS NLP solver
reslim	Time limit for AlphaECP (in seconds)	GAMS reslim

5.3.4.2 Algorithmic options for advanced users

Option	Description	Default
CUTdelcrit	Cutting plane strategy	3
ECPbeta	Updating multiplier if MIP is infeasible	1.3
ECPdumpsol	Write encountered solutions to gdx files	0
ECPgamma	Updating multiplier when verifying solution	2.0
ECPiterlim	Maximum number of AlphaECP iterations	-1
ECPloglevel	Level of AlphaECP output to statusfile	0
ECPpcostrategy	Pseudo-convex objective function strategy	3
ECPretsol	Return solution (1.MIP/2.NLP/3.QUALITY/4.PERFORMANCE)	2
ECPstart	User specified start-point	3
ECPstrategy	AlphaECP strategy	2
solverlink	Solverlink for NLP and MIP sub-solver	5
solvetrace	Filename of solvetrace file	
solvetracetime	Time interval when a trace record is written	1
TOLeptsf	Pseudo-convex objective function termination tolerance	1e-3
TOLeptsg	Constraint tolerance	1e-3
TOLeptsz	Distance tolerance for a new linearization	1e-1
TOLgrad	Gradient tolerance	1e-6
TOLinfband	Infinity bound (MIP variable bound)	1e10

5.3.4.3 MIP Solver related options

Option	Description	Default
MIPloglevel	Level of MIP solver output	0
MIPoptcr	Relative MIP gap in intermediate sub-problems	1.0

Option	Description	Default
MIPoptcrlim	Initial MIPoptcr interval before MIPoptcr reduction	200

5.3.4.4 NLP Solver related options

Option	Description	Default
NLPcall	NLP strategy	5
NLPcalliter	NLP solver call at next (incremental) iteration	0
NLPlimsameint	NLP call after a number of recurring integer solutions	5
NLPloglevel	Level of NLP solver output	0
NLPpreslim	NLP time limit per call	0

5.3.5 Detailed Descriptions of AlphaECP Options

CUTdelcrit (*integer*): Cutting plane strategy [↔](#)

Default: 3

value	meaning
0	Do not remove any valid cuts.
1	As 0 and allow temporary cuts at semirandom points if normal cuts can not be made.
2	Allow temporary cuts and cut reselection, and use memory to save points and cuts.
3	As 2 and call the reselection heuristic before termination to improve the solution.

CUTnrcuts (*real*): Cut generation pace [↔](#)

The number of linearizations that are generated during an iteration can be chosen by AlphaECP, proportional to the number of violating constraints, or can be determined by a fixed amount. Furthermore, the cut reselection [CUTdelcrit](#) ≥ 2 adds cuts to the problem so that the requested cut generation pace is taken into consideration.

Default: 0

value	meaning
0	Let AlphaECP decide.
$0 < n < 1$	Number of linearizations = $n \times$ the number of linearizations that is possible to generate.
> 1	Specifies the number of linearizations to generate.

ECPbeta (*real*): Updating multiplier if MIP is infeasible [↔](#)

In case of an infeasible MIP solution, the invalid cuts are updated with the [ECPbeta](#) multiplier.

Range: $[1.001, \infty]$

Default: 1.3

ECPdumpsol (*integer*): Write encountered solutions to gdx files [↔](#)

Default: 0

value	meaning
0	No.
1	Solutions that the NLP solver found.
2	Solutions that the NLP or MIP solver found.

ECPgamma (*real*): Updating multiplier when verifying solution [↔](#)

If a MINLP solution is obtained but some cuts are not valid underestimators they are updated with the [ECPgamma](#) multiplier in order to make them into valid underestimators.

Range: $[1.001, \infty]$

Default: 2.0

ECPiterlim (*integer*): Maximum number of AlphaECP iterations [↔](#)

This is the maximum number of iterations given to AlphaECP to perform the optimization. Value -1 deactivates the AlphaECP iteration limit.

Default: -1

value	meaning
-1	No limit.
≥ 0	Specifies an iteration limit.

ECPloglevel (*integer*): Level of AlphaECP output to statusfile [↔](#)

Default: 0

value	meaning
0	No additional output to statusfile.
1	Report solutions. Report all encountered solutions with their corresponding variable levels.
2	Report main actions at iteration level (available for minimization problems).
3	Report main actions at linearization level (available for minimization problems).
4	Full reporting. Report the main actions taken, the linearizations, function values, and solution points for every iteration and line search details (available for minimization problems).

ECPmaster (*integer*): Master strategy (0=User 1=Convex) [↔](#)

The master strategy sets some options in order to solve a model with specific characteristics more efficiently. The affected options are noted in the log output. The set options takes precedence over the value set by the user for the affected options.

Default: 0

value	meaning
0	Use only user defined options.
1	The model is convex. Set option ECPstrategy and CUTdelcrit.

ECPpcostrategy (*integer*): Pseudo-convex objective function strategy ↩

Default: 3

value	meaning
1	Remove support. Remove old support planes when a new pseudo-convex problem is formed.
2	Replace support. Replace old support planes with linearizations of the reduction constraint when a new pseudo-convex problem is formed.
3	Remove support and line search. Remove old support planes when a new pseudo-convex problem is formed and perform a line search when it is possible.
4	Replace support and line search. Replace old support planes with linearizations of the reduction constraint when a new pseudo-convex problem is formed and perform a line search when it is possible.

ECPretsol (*integer*): Return solution (1.MIP/2.NLP/3.QUALITY/4.PERFORMANCE) ↩

The reported solution can be extracted from either the MIP or NLP solver result. If the MIP solution is returned only the primal values are available.

Default: 2

value	meaning
1	Choose MIP solution if it is available.
2	Choose NLP solution if it is available.
3	Choose the solution with the best tolerance.
4	Choose the solution with the best objective value.

ECPstart (*integer*): User specified start-point ↩

Define which variable levels are used when the optimization is started.

Default: 3

value	meaning
0	Do not use a start-point; start the algorithm by solving the linear part (MIP) of the problem.
1	Use the user specified startpoint, but adjust the variable levels with a small value.
2	Use the exact start-point set by the user.
3	Use the exact start-point if linearly feasible; else adjust variable levels with a small value.

ECPstrategy (*integer*): AlphaECP strategy ↩

Default: 2

value	meaning
1	Convex strategy. Ensures global optimality for problems with convex objective function and convex constraints.
2	Pseudo-convex constraints. Ensures global optimality for problems with convex objective function and pseudo-convex constraints.
3	Pseudo-convex objective. Ensures global optimality for problems with pseudo-convex objective function and pseudo-convex constraints. The reformulation of a non-linear objective function into a constraint must be done in a specific way. The requirement is that the objective variable must be in a linear part of the non-linear function. Assuming that the minimized or maximized variable is called objvar, the reformulation can be done as follows: (objective function expression) - objvar =E= 0. Furthermore, this strategy can effectively use a feasible start-point.
4	Pseudo-convex objective, but first complete with ECPstrategy 2. (Only the necessary linearizations are removed when the ECPstrategy is changed.)
5	Pseudo-convex objective, but find the first solution with ECPstrategy 2. (Only the necessary linearizations are removed when the ECPstrategy is changed.)

MIPloglevel (*boolean*): Level of MIP solver output [↔](#)

By default the detailed log of the MIP solver is suppressed in the AlphaECP log stream. If this option is turned on and the GAMS LogOption is set to 1 or 3, the MIP log will be merged into the AlphaECP log.

Default: 0

value	meaning
0	No output.
1	MIP solver log goes to GAMS log.

MIPnrsols (*integer*): Upper limit of considered MIP solutions per MIP call [↔](#)

When the MIP solver returns several solutions the most suitable solution is chosen. Many times the solutions from the MIP solver are similar and a larger number might help to find a feasible MINLP solution if the constraints are almost satisfied. See [MIPsolstrat](#) to change the solution collection strategy.

Range: [1, ∞]

Default: 50

MIPoptcr (*real*): Relative MIP gap in intermediate sub-problems [↔](#)

The relative stopping tolerance sent to the MIP solver for intermediate MIP problems. Note that the [MIPoptcr](#) value is decreased automatically to zero during the optimization.

Range: [0, 1]

Default: 1.0

MIPoptcrlim (*integer*): Initial MIPoptcr interval before MIPoptcr reduction [↔](#)

The **MIPoptcr** parameter is reduced in steps: From 1 to 0.5 to 0.3 to 0.2 to 0.1 to 0.0. The first reduction is at iteration **MIPoptcrlim**. **MIPoptcrlim** defines a step reduction at specific iterations (next reduction at iteration = the iteration number for this reduction multiplied by two). Note that a step reduction can also be caused by other reasons. If **MIPoptcrlim** is 200 then **MIPoptcr** is reduced at the following iterations: 200, 400, 800, etc.

Range: $[1, \infty]$

Default: 200

MIPsolstrat (*integer*): MIP solution collection strategy ↩

Default: 1

value	meaning
0	Instruct MIP solver to return only one solution.
1	Instruct MIP solver to return any solutions encountered during MIP procedure.
2	Instruct MIP solver to search for solutions to obtain requested number MIPnrsols solutions.
3	As 2, but also require the solutions to fulfill MIPoptcr ≥ 0.2 .
4	Let AlphaECP decide.

MIPsolver (*string*): MIP solver for sub-problems and . option file number ↩

solver[.n] Solver is the name of the GAMS MIP solver and **n** is the integer corresponding to **optfile**. The option file is appended to the option file, that is written by AlphaECP. Hence, the specified options take precedence over the options set by AlphaECP. If **.n** is missing, the **optfile** is treated as zero i.e. the MIP solver will not look for a options file specified by the user. This option can be used to overwrite the default that uses the MIP solver specified with an **Option NLP = solver;** statement or the default GAMS solver for NLP.

Default: GAMS MIP **solver**

NLPcall (*integer*): NLP strategy ↩

Determine when the NLP solver is called.

Default: 5

value	meaning
0	No output.
1	Call the NLP solver at end of AlphaECP algorithm.
2	As 1 and when a better solution is found.
3	As 2 and when the same integer solution is encountered NLPlimsameint times.
4	Let AlphaECP decide.
5	Let AlphaECP decide and add noise to the variable levels before call.

NLPcalliter (*integer*): NLP solver call at next (incremental) iteration ↩

Specify an iteration interval for the NLP solver calls.

Default: 0

NLPlimsameint (*integer*): NLP call after a number of recurring integer solutions ↩

If the same integer solution is encountered `NLPlimsameint` times in a row then the NLP solver is called. The counter is reset after the NLP solver is called.

Range: $[1, \infty]$

Default: 5

NLPloglevel (*boolean*): Level of NLP solver output ↩

By default the detailed log of the NLP solver is suppressed in the AlphaECP log stream. If this option is turned on and the GAMS `LogOption` is set to 1 or 3, the NLP log will be merged into the AlphaECP log.

Default: 0

value	meaning
0	No output.
1	NLP solver log goes to GAMS log.

NLPreslim (*real*): NLP time limit per call ↩

The time limit (in seconds) given to the chosen NLP solver at each NLP solver call. Setting this option to 0 calculates a time limit which is relative to the problem size.

Default: 0

NLPsolver (*string*): NLP solver for sub-problems and . option file number ↩

`solver[.n]` Solver is the name of the GAMS NLP solver that should be used in the root node, and `n` is the integer corresponding to optfile. If `.n` is missing, the optfile is treated as zero, i.e., the NLP solver will not look for an options file. This option can be used to overwrite the default that uses the NLP solver specified with an `Option NLP = solver;` statement or the default GAMS solver for NLP.

Default: GAMS NLP solver

reslim (*real*): Time limit for AlphaECP (in seconds) ↩

Default: GAMS reslim

solverlink (*integer*): Solverlink for NLP and MIP sub-solver ↩

Default: 5

value	meaning
1	Call NLP and MIP solver via script.
2	Call NLP and MIP solver via module.
5	Call NLP and MIP solver in memory.

solvetrace (*string*): Filename of solvetrace file ↩

solvetracetime (*real*): Time interval when a trace record is written ↩

Default: 1

TOLepsf (*real*): Pseudo-convex objective function termination tolerance ↔

Maximum allowed absolute difference between the nonlinear and the MIP objective function value (used only in [ECPstrategy 3](#)).

Range: [1e-20, 1]

Default: 1e-3

TOLepsg (*real*): Constraint tolerance ↔

The nonlinear constraint tolerance defines the maximum value that a nonlinear constraint may violate. For example, a constraint required to be zero may hold a value +/- TOLepsg at a solution.

Range: [1e-20, 1]

Default: 1e-3

TOLepsz (*real*): Distance tolerance for a new linearization ↔

The maximum perpendicular distance between a valid cutting plane and its generation point (MIP solution).

Range: [1e-20, 1]

Default: 1e-1

TOLgrad (*real*): Gradient tolerance ↔

The absolute value of a gradient's partial derivative must be above TOLgrad value in order for it to be considered nonzero.

Range: [1e-20, 1]

Default: 1e-6

TOLinfbd (*real*): Infinity bound (MIP variable bound) ↔

All variables must have a positive and a negative finite bound in order to ensure a bounded MIP problem. The finite bound value TOLinfbd will be applied to single or double unbounded variables.

Default: 1e10

5.3.6 FAQ

- What are good settings to solve a convex problem?
Use [ECPmaster 1](#).
- What are good settings if the solution speed is essential?
Try [ECPstrategy 1](#) and [CUTdelcrit 1](#) to see if using multiple threads for the MIP solver improves the solution speed. However, there is considerable chance that a feasible solution for a non-convex problem with nonlinear equality constraints cannot be found.
- What are good settings when the solution quality is essential?
Use [NLPcalliter 1](#) and [MIPsolstrat 4](#) or [3](#), and also try different values, for [CUTnrcuts](#) option, for example 0.1.
- The objective function is non-linear, should the default [ECPstrategy](#) be used?
If the objective function constraint can be written in the required form of [ECPstrategy 3](#) then this strategy may find a better solution. If the constraints and the objective function are pseudo-convex the global optimal solution will be found.

5.4 AMPL

5.4.1 Introduction

GAMS/AMPL allows users to solve GAMS models using solvers within the AMPL modeling system. The GAMS/AMPL link comes free with any GAMS system. Users must have a licensed AMPL system installed and have the AMPL executable in their path.

To run GAMS/AMPL, just specify the solver as `ampl`. For example, if we wish to solve the *transport.gms* model, we would run

```
>> gams transport.gms lp=ampl
```

For other GAMS solvers, options can be passed on via solver option files. GAMS/AMPL specific options are described in the section [GAMS/AMPL Options](#).

By default, GAMS/AMPL returns a model status of 14 (no solution) and a solver return status of 1 (normal completion), provided the link is executed normally. This includes the case where the AMPL executable is not found.

GAMS external equations and extrinsic functions cannot be used with GAMS/AMPL.

5.4.2 AMPL Path

GAMS searches for an AMPL executable using the following hierarchy:

- Via the options [AmplPath](#) and [RunAmpl](#) within a GAMS/AMPL solver options file.
- An `amplpath.txt` file located in the GAMS system directory specifying the path of the AMPL executable.
- The system path.

For example, GAMS will first search for the AMPL executable within the `ampl.opt` file, if specified. If not found, it will search within the GAMS system directory for a file called `amplpath.txt` specifying the AMPL directory. If `amplpath.txt` is still not found, GAMS will try the system path.

If no AMPL executable is found, the user will see a message similar to

```
AMPL Link 2.0      Jul  4, 2012 23.9.5 WIN 36376.36401 VS8 x86/MS Windows

--- No AmplPath option or "amplpath.txt" file found
--- System PATH will be used
```

There may also be an output indicating that AMPL was not found, either because it was not installed or because it was not found in the system path.

5.4.3 GAMS/AMPL Options

Option	Description	Default
AmplPath	Path to AMPL System files	
DotMod	AMPL input file name	ampl.mod
Option	Verbatim AMPL options For example, to run AMPL/MINOS with the options <code>timing=3 outlev=2</code> , put the following entry into your <code>ampl.opt</code> file: <code>option minos_options "timing=3 outlev=2";</code>	
RunAmpl	Name of AMPL executable	ampl
TolNone	Tolerance to interpret status none	1e-12

5.5 ANTIGONE

Christodoulos A. Floudas, floudas@titan.princeton.edu; Computer-Aided Systems Laboratory; Department of Chemical and Biological Engineering; Princeton University

Ruth Misener, r.misener@imperial.ac.uk; Centre for Process Systems Engineering; Imperial College London

16 April 2013 : ANTIGONE 1.0

5.5.1 Introduction

ANTIGONE, Algorithms for coNTinuous / Integer Global Optimization of Nonlinear Equations, is a deterministic general mixed-integer nonlinear global optimization framework [175] [176] [178] [177] [181] .

MINLP is defined:

$$\begin{aligned}
 \min \quad & f_0(\mathbf{x}, \mathbf{y}, \mathbf{z}) \\
 \text{s.t.} \quad & b_m^{\text{LO}} \leq f_m(\mathbf{x}, \mathbf{y}, \mathbf{z}) \leq b_m^{\text{UP}} \quad \forall m \in \{1, \dots, M\} \\
 & \mathbf{x} \in \mathbb{R}^C; \mathbf{y} \in \{0, 1\}^B; \mathbf{z} \in \mathbb{Z}^I
 \end{aligned} \tag{MINLP}$$

where C , B , I , and M represent the number of continuous variables, binary variables, integer variables, and constraints, respectively. Parameters vectors $\mathbf{b}_m^{\text{LO}}$ and $\mathbf{b}_m^{\text{UP}}$ bound the constraints. We assume that it is possible to infer finite bounds $[x_i^L, x_i^U]$ on the variables participating in nonlinear terms f_m and that the image of f_m is finite on $\mathbf{x}$. Typical expressions for $f_0(\mathbf{x}, \mathbf{y}, \mathbf{z})$ and $f_m(\mathbf{x}, \mathbf{y}, \mathbf{z})$ are:

$$\begin{aligned}
 f_m(\mathbf{x}, \mathbf{y}, \mathbf{z}) = & c_m + a_m^T [\mathbf{x}; \mathbf{y}; \mathbf{z}] + [\mathbf{x}; \mathbf{y}; \mathbf{z}]^T Q_m [\mathbf{x}; \mathbf{y}; \mathbf{z}] \\
 & + \sum_{s=1}^{S_m} c_{s_m} \cdot \prod_{c=1}^C x_c^{p_{s_m, c}} + \sum_{e=1}^{E_m} c_{e_m} \cdot e^x + \sum_{\ell=1}^{L_m} c_{\ell_m} \cdot \log x
 \end{aligned}$$

where the powers $p_{s_m, c}$ are constant reals; c_m , a_m , Q_m , c_{s_m} , c_{e_m} , c_{ℓ_m} are constant coefficients; S_m , E_m , L_m are the number of signomial, exponential, and logarithmic terms, respectively.

As illustrated in Figure 5.1, ANTIGONE responds dynamically to exploit special structure within (MINLP). ANTIGONE falls broadly into the category of branch-and-bound global optimization because it: generates and solves convex relaxations of the nonconvex MINLP that rigorously bound the global solution; finds feasible solutions via local optimization; divides and conquers the feasible set to generate a sequence of convex relaxations converging to the global optimum [97] [94] .

Figure 5.1 Given an MINLP optimization problem, ANTIGONE reformulates the model, detects special structure in the reformulated MINLP, solves the optimization problem, and returns the model with respect to the original problem variables

5.5.1.1 Licensing and software requirements

Using GAMS/ANTIGONE requires

1. an ANTIGONE license,
2. a CPLEX license, and
3. a CONOPT or SNOPT license.

ANTIGONE performs equivalently to [GAMS/GloMIQO](#) in the case where all nonlinearities in (MINLP) are quadratic; an ANTIGONE license includes the use of GloMIQO.

5.5.1.2 Running GAMS/ANTIGONE

GAMS/ANTIGONE solves: NLP; MINLP; RMINLP; QCP; MIQCP; RMIQCP; CNS. If GAMS/ANTIGONE is not the default solver for these models, it can be called using the following command before the `solve` statement:

```
option nlp=antigone, minlp=antigone, rminlp=antigone;
```

5.5.2 GAMS/ANTIGONE Output

The log output shown below is generated using the MINLP model `cecil_13` from the MINLPLib.

ANTIGONE: Algorithms for coNTinuous/Integer Global Optimization; Version 1.0

Ruth Misener and Christodoulos A. Floudas

Computer-Aided Systems Laboratory (CASL)

Department of Chemical & Biological Engineering; Princeton University

Before Pre-processing:

840 Variables
660 Continuous
180 Binary

929 Equations

After Pre-processing:

520 Variables

418 Continuous

102 Binary

499 Equations

291 Linear

208 Nonconvex nonlinear

232 Nonlinear Terms

232 Signomial

730 Possible Reformulation Linearization Technique (RLT) equations

34 RLT Equations Added Outright to Formulation

Constituent Libraries:

CPLEX Solving relaxations

CONOPT Finding feasible points

LAPACK Addressing linear systems

Boost Bounding Intervals

5.5.3 Summary of ANTIGONE Options

5.5.3.1 General Options

Option	Description	Default
abs_opt_tol	absolute stopping tolerance	GAMS optca
dumpsolutions	name of solutions index.gdx file for writing alternate solutions	
max_number_nodes	node limit	GAMS nodlim
max_time	resource limit	GAMS reslim
readparams	read secondary option file in ANTIGONE syntax	
rel_opt_tol	relative stopping tolerance	GAMS optcr
trydual	call CONOPT or SNOPT to produce duals	5

5.5.3.2 Options for Solving the MILP Relaxations

Option	Description	Default
cplex_optfile	read a secondary GAMS/CPLEX options file that will be applied to every LP and MILP subsolve	
cut_generation_epsilon	absolute violation threshold for separating hyperplanes	1e-4
nominal_time_limit	nominal time limit for solving MILP subproblems	100
populate_solution_pool	emphasis on generating starting points	3

5.5.3.3 Options for Finding Feasible Solutions

Option	Description	Default
conopt_optfile	read a secondary GAMS/CONOPT options file that will be applied to every NLP subsolve	
feas_soln_time_limit	time limit (s) for an NLP solve	30
feas_tolerance	absolute feasibility tolerance	1e-6
nlp_solver	use CONOPT or SNOPT to find feasible solutions	conopt

5.5.3.4 Options for Branching

Option	Description	Default
branching_bounds_push_away	branch a minimum fraction away from the variable bounds	0.1
branching_weight	branch on a convex combination of midpoint and solution	0.25
num_reliability_tests	number of strong branching initialization tests	8
reliability_branching	heuristic choice for building reliable pseudocosts	error
reliability_branching_mu	score parameter for building reliability	0.15
use_reliability_branching	use reliability branching?	1

5.5.3.5 Options for Bounding

Option	Description	Default
fbbt_improvement_bound	bounds reduction improvement threshold needed to exit FBBT loop	0.999
max_fbbt_iterations	maximum number of FBBT iterations	50
max_obbt_iterations	maximum number of OBBT iterations	30
max_time_each_obbt	time limit (s) for each OBBT LP	10
obbt_improvement_bound	bounds reduction improvement threshold	0.95
use_obbt	use optimality-based bounds tightening?	1

5.5.3.6 Options for Logging to the Console

Option	Description	Default
logging_freq	how often should we log progress to the console?	5
logging_level	logging information level	-1
print_options	print the option parameter choices used in a single run?	1

5.5.3.7 Options for Addressing Special Structure

Option	Description	Default
adaptive_add_rlt	use the dynamic approach to adaptively determine deep RLT cuts?	1
adaptive_add_rlt_tree_depth	tree depth for heuristic that adaptively determines deep RLT cuts	3
add_bilinear_terms	allow addition of nonconvex bilinear terms to generate deep RLT cuts	1
convexity_cuts	derive convexity-based separating cuts for multivariable terms?	1
dominant_ec_only	add only the low-dimension edge-concave aggregations introducing dominant cuts into relaxations?	1
eigenvector_projections	use eigenvector projections as additional cuts?	1

Option	Description	Default
eigenvector_projection_partitioning	allow partitioning on eigenvector projections?	1
low_dim_edge_concave_agg	use low-dimension edge-concave aggregations?	1
max_partitioned_quantities	number of partitioned quantities	0
max_rlt_cuts	maximum number of violated RLT cuts to add before resolving the relaxation?	100
naive_add_ec	naively integrate all low-dimension edge-concave aggregations into relaxations?	0
naive_add_rlt	naively add all RLT cuts to the relaxations?	0
number_of_partitions	how many partitions per variable?	1
partitioning_scheme	Partitioning scheme can be linear or logarithmic	linear
piecewise_linear_partitions	use piecewise-linear partitioning?	0
rlt	find RLT variable/equation and equation/equation pairs?	1
use_alpha_bb	apply globally-valid alphaBB cuts to tighten a node relaxation	1
use_edge_concave_dynamic	apply locally-valid edge-concave cuts to tighten a node relaxation	1

5.5.4 Detailed Descriptions of ANTIGONE Options

abs_opt_tol (*real*): absolute stopping tolerance [↔](#)

Default: GAMS optca

adaptive_add_rlt (*boolean*): use the dynamic approach to adaptively determine deep RLT cuts? [↔](#)

In the first few levels of the branch-and-bound tree, query the RLT equations after solving an initial relaxation. Add violated equations to the relaxation and resolve. Track the most commonly-violated equations and include those cuts in later nodes.

Default: 1

adaptive_add_rlt_tree_depth (*integer*): tree depth for heuristic that adaptively determines deep RLT cuts [↔](#)

To the specified tree depth, solve the relaxation of a node twice if RLT equations are violated. After this depth, automatically add the most commonly violated cuts to the solution of each node

Range: [1, 100]

Default: 3

add_bilinear_terms (*boolean*): allow addition of nonconvex bilinear terms to generate deep RLT cuts [↔](#)

Default: 1

branching_bounds_push_away (*real*): branch a minimum fraction away from the variable bounds [↔](#)

Range: $[0, 0.5]$

Default: 0.1

branching_weight (*real*): branch on a convex combination of midpoint and solution ↩

The branching weight specifies the emphasis on the midpoint of a variable, so larger branching weights imply branching closer to the center of a variable range.

Range: $[0, 1]$

Default: 0.25

conopt_optfile (*string*): read a secondary GAMS/CONOPT options file that will be applied to every NLP subsolve ↩

Gain direct access to the [GAMS/CONOPT options](#). The value of the string should match the name of the GAMS/CONOPT options file.

convexity_cuts (*boolean*): derive convexity-based separating cuts for multivariable terms? ↩

Default: 1

cplex_optfile (*string*): read a secondary GAMS/CPLEX options file that will be applied to every LP and MILP subsolve ↩

Gain direct access to the [GAMS/CPLEX options](#). Specifying an options file allows, for example, the possibility of running the CPLEX subsolver with multiple threads. The value of the string should match the name of the GAMS/CPLEX options file.

cut_generation_epsilon (*real*): absolute violation threshold for separating hyperplanes ↩

Absolute violation threshold to generate separating hyperplanes for convex multivariable terms

Range: $[1e-7, 10]$

Default: $1e-4$

dominant_ec_only (*boolean*): add only the low-dimension edge-concave aggregations introducing dominant cuts into relaxations? ↩

Default: 1

dumpsolutions (*string*): name of solutions index gdx file for writing alternate solutions ↩

The GDX file specified by this option will contain a set call **index** that contains the names of GDX files with the individual solutions. For details see example model **dumpsol** in the GAMS Test Library.

eigenvector_projections (*boolean*): use eigenvector projections as additional cuts? ↩

Default: 1

eigenvector_projection_partitioning (*boolean*): allow partitioning on eigenvector projections? ↩

Default: 1

fbbt_improvement_bound (*real*): bounds reduction improvement threshold needed to exit FBBT loop ↩

Range: $[0, 1]$

Default: 0.999

feas_soln_time_limit (*real*): time limit (s) for an NLP solve [↔](#)

Range: $[1, \infty]$

Default: 30

feas_tolerance (*real*): absolute feasibility tolerance [↔](#)

Default: $1\text{e-}6$

logging_freq (*real*): how often should we log progress to the console? [↔](#)

Wait at least the specified time in seconds before next output to the console

Range: $[1, \infty]$

Default: 5

logging_level (*integer*): logging information level [↔](#)

Log to the console at the specified level (-1: default; 0: minimal logging; 3: extensive logging)

Default: -1

value	meaning
-1	minimal plus warnings
0	minimal
1	entering info
2	updating info
3	includes Cplex updates

low_dim_edge_concave_agg (*boolean*): use low-dimension edge-concave aggregations? [↔](#)

Default: 1

max_fbbt_iterations (*integer*): maximum number of FBBT iterations [↔](#)

Range: $[1, 100]$

Default: 50

max_number_nodes (*integer*): node limit [↔](#)

Default: GAMS nodlim

max_obbt_iterations (*integer*): maximum number of OBBT iterations [↔](#)

Range: $[1, 100]$

Default: 30

max_partitioned_quantities (*integer*): number of partitioned quantities [↔](#)

Range: [0, 50]

Default: 0

max_rlt_cuts (*integer*): maximum number of violated RLT cuts to add before resolving the relaxation? [↔](#)

Range: [1, 1000]

Default: 100

max_time (*real*): resource limit [↔](#)

Default: GAMS `reslim`

max_time_each_obbt (*real*): time limit (s) for each OBBT LP [↔](#)

Range: [1, 100]

Default: 10

naive_add_ec (*boolean*): naively integrate all low-dimension edge-concave aggregations into relaxations? [↔](#)

Default: 0

naive_add_rlt (*boolean*): naively add all RLT cuts to the relaxations? [↔](#)

Default: 0

nlp_solver (*string*): use CONOPT or SNOPT to find feasible solutions [↔](#)

Note, that independent of the setting for this option, for the initial NLP solve from the user provided starting point, always CONOPT is used, if available. Further, for the final NLP solve (see [trydual](#)), always CONOPT is used, if available, otherwise SNOPT is used.

Default: `conopt`

value	meaning
<code>conopt</code>	Conopt
<code>snopt</code>	Snopt

nominal_time_limit (*real*): nominal time limit for solving MILP subproblems [↔](#)

Nominal time limit for solving MILP subproblems. Terminate long-running MILP subproblems over this time limit once they reach an integer feasible point

Range: [0.1, 1000]

Default: 100

number_of_partitions (*integer*): how many partitions per variable? [↔](#)

Range: [0, 16]

Default: 1

num_reliability_tests (*integer*): number of strong branching initialization tests [↔](#)

Range: [1, 100]

Default: 8

obbt_improvement_bound (*real*): bounds reduction improvement threshold [↔](#)

Bounds reduction improvement threshold needed to exit OBBT loop. This parameter also determines whether to continue obbt in child; if the parent bound improvement is less than this threshold, then child node won't try OBBT.

Range: [0, 1]

Default: 0.95

partitioning_scheme (*string*): Partitioning scheme can be linear or logarithmic [↔](#)

Linear partitioning uses a number of binary variables linear in the number of partitions while logarithmic partitioning uses a number of binary variables logarithmic in the number of breakpoints. Linear partitioning tends to be numerically favorable for a few breakpoints while logarithmic partitioning is better for a larger number of breakpoints.

Default: `linear`

value	meaning
<code>linear</code>	Linear partitioning
<code>logarithmic</code>	Logarithmic partitioning

piecewise_linear_partitions (*boolean*): use piecewise-linear partitioning? [↔](#)

Default: 0

populate_solution_pool (*integer*): emphasis on generating starting points [↔](#)

Emphasis on generating many starting points for NLP solves using the CPLEX solution pool feature. Larger number implies more starting points.

Range: [0, 4]

Default: 3

print_options (*boolean*): print the option parameter choices used in a single run? [↔](#)

Default: 1

readparams (*string*): read secondary option file in ANTIGONE syntax [↔](#)

reliability_branching (*string*): heuristic choice for building reliable pseudocosts [↔](#)

Default: `error`

value	meaning
error	Max Error Branching
forward	Forward branching
reverse	Reverse branching

reliability_branching_mu (*real*): score parameter for building reliability [↔](#)

Range: $[0, 1]$

Default: 0.15

rel_opt_tol (*real*): relative stopping tolerance [↔](#)

Default: GAMS optcr

rlt (*boolean*): find RLT variable/equation and equation/equation pairs? [↔](#)

Default: 1

trydual (*real*): call CONOPT or SNOPT to produce duals [↔](#)

Spend the specified amount of time in seconds or less in producing a dual solution by calling CONOPT or SNOPT.

Range: $[0, \infty]$

Default: 5

use_alpha_bb (*boolean*): apply globally-valid alphaBB cuts to tighten a node relaxation [↔](#)

Default: 1

use_edge_concave_dynamic (*boolean*): apply locally-valid edge-concave cuts to tighten a node relaxation [↔](#)

Default: 1

use_obbt (*boolean*): use optimality-based bounds tightening? [↔](#)

Default: 1

use_reliability_branching (*boolean*): use reliability branching? [↔](#)

Default: 1

5.5.5 ANTIGONE Algorithmic Features

As illustrated in Figure 5.1, the primary algorithmic features in ANTIGONE are [reformulating model input](#), [elucidating special structure](#), and [branch-and-bound global optimization](#) [175] [176] [178] [177] [181].

Figure 5.2 (a) A binary tree represents algebraic expressions; (b) A factorable programming tree employs operator-based relaxations; (c) The ANTIGONE transformation to a flattened expression tree allows access to term-based underestimators; Convex form $(x_1 - 4)^2$ is not expanded.

5.5.5.1 Reformulating Model Input

As illustrated in Figure 5.2, ANTIGONE transforms a factorable programming tree into a flattened expression tree to capitalize on the development of tight convex underestimators for specific classes of nonlinear terms. ANTIGONE extends the efficacy of hybrid strategies by meaningfully integrating mutually reinforcing operator- and term-based strategies [43] [105] [177]. This approach reformulates towards multivariable terms with specialized underestimators while maintaining a tree-like representation of powers that cannot be distributed and convex operators that can be exploited by dynamic cut generation.

5.5.5.2 Elucidating Special Structure

After reformulating the user-defined MINLP, ANTIGONE detects special mathematical structure that it will exploit in the branch-and-cut phase (Section [Branch-and-Bound Global Optimization](#)). The types of special structure that ANTIGONE considers are: reformulation-linearization technique (RLT) equations; convexity/concavity; edge-convexity/edge-concavity; α BB relaxations; term-specific underestimators [175] [176] [178] [177] [181].

- **RLT** multiplies every pairwise combination of: variables; nonlinear terms; equations [18] [158] [176] [177] [181] [221] [222] [223] [224] [225]. ANTIGONE saves the combinations that do *not* introduce new terms into the model formulation and updates these equations at every node of the branch-and-cut tree. Special RLT equations are added directly to the model formulation; other RLT equations are used as cutting planes and integrated into the feasibility-based bounds tightening routines.
- **Convexity/Concavity** permits the easy generation of a cutting plane at a point $\hat{x}$:

$$\begin{aligned} f(x) &\geq f(\hat{x}) + f'(\hat{x}) \cdot (x - \hat{x}) & (\text{convex}) \\ f(x) &\leq f(\hat{x}) + f'(\hat{x}) \cdot (x - \hat{x}) & (\text{concave}) \end{aligned}$$

Based on interval arithmetic, terms and multi-term expressions are labeled as always/sometimes/never convex/ concave; this information is used in the branch-and-cut phase.

Figure 5.3 Inheritance Structure of Base Class Term

- **Edge-Convexity/Edge-Concavity** implies a vertex polyhedral envelope; ANTIGONE labels terms and multi-term expressions as always/sometimes/never edge-convex/edge-concave with a simple interval arithmetic test [171] [227] [228] [229] .
- α BB underestimators convexify an expression with univariate quadratics [7] [8] [16] [91] [165]; ANTIGONE uses α BB to relax aggregates of bilinear terms.
- **Term-Specific Underestimators** are diagrammed in Figure 5.3; their implementation is based on work available in the open literature [75] [74] [90] [106] [157] [163] [161] [162] [166] [171] [175] [193] [227] [228] [230] .

5.5.5.3 Branch-and-Bound Global Optimization

After the reformulation and special structure detection phases, ANTIGONE initiates a branch-and-cut global optimization algorithm that generates tight convex underestimators, dynamically generates separating hyperplanes, bounds the variables [8] [16] [7] [18] [33] [71] [72] [150] [208] [209] [224] [225] [243]; branches on the search space [4] [33], and finds feasible solutions.

5.6 BARON

Nick Sahinidis, The Optimization Firm, LLC, niksah@minlp.com, <http://www.minlp.com>

5 June 2015 :

5.6.1 Introduction

The Branch-And-Reduce Optimization Navigator (BARON) is a GAMS solver for the *global solution* of nonlinear (NLP) and mixed-integer nonlinear programs (MINLP).

While traditional NLP and MINLP algorithms are guaranteed to converge only under certain convexity assumptions, BARON implements deterministic global optimization algorithms of the branch-and-bound type that are *guaranteed to provide global optima* under fairly general assumptions. These include the existence of finite lower and upper bounds on nonlinear expressions in the NLP or MINLP to be solved.

BARON implements algorithms of the branch-and-bound type enhanced with a variety of constraint propagation, interval analysis, and duality techniques for reducing ranges of variables in the course of the algorithm. Rigorous relaxations are constructed by enlarging the feasible region and/or underestimating the objective function.

Parts of the BARON software were created at the University of Illinois at Urbana-Champaign. The algorithms implemented in the software, the theory behind them, and some related applications are (partly) described in [208] [73] [209] [212] [123] [160] [107] [239] [220] [240] [214] [108] [210] [230] [231] [232] [235] [236] [216] [211] [213] [10] [233] [215] [234] [56] [25] [199] [26] [140] [141] [262] [263] [142] [264] [27] .

5.6.1.1 Licensing and software requirements

In order to use GAMS/BARON, users will need to have a GAMS/BARON license. BARON comes with several embedded LP/MIP and NLP solvers (CBC; IPOPT, FilterSD, FilterSQP). Additionally, through BARON's `lpsol` and `nlpsol` options, GAMS/BARON users can expedite convergence by accessing CPLEX and XPRESS to solve BARON's LP/MIP subproblems and any GAMS NLP solver, such as CONOPT, to solve BARON's NLP subproblems. These solvers need to be licensed separately.

By default, GAMS/BARON will attempt to use CPLEX as the LP solver and select an NLP solver automatically. The user can use the options `LPSol` and `NLPSol` to specify the LP or NLP solver. If the user does not have a license for the default or user-specified LP solver, BARON will switch to CLP. If the user does not have a license for the user-specified NLP solver, BARON will automatically select a licensed NLP solver and may default to IPOPT if no other NLP solver is available. BARON can be used without a local NLP solver by setting `DoLocal` and `NumLoc` to 0.

5.6.1.2 Running GAMS/BARON

BARON is capable of solving models of the following types: LP, MIP, RMIP, NLP, DNLP, RMINLP, and MINLP. If BARON is not specified as the default solver for these models, it can be invoked by issuing the following command before the solve statement:

```
option <modeltype>=baron;
```

where `<modeltype>` stands for LP, MIP, RMIP, QCP, MIQCP, RMIQCP, CNS, NLP, DNLP, MINLP, or RMINLP.

5.6.2 Model requirements

In order to achieve convergence to global optimality, additional model constraints may be required. The additional constraints may speed up solver time and increase the probability of success.

5.6.2.1 Variable and expression bounds

All nonlinear expressions in the mathematical program to be solved must be bounded below and/or above. It is important that finite lower and upper bounds be provided by the user on all problem variables. Note that providing finite bounds on variables alone may not suffice to guarantee finite bounds on nonlinear expressions arising in the model.

For example, consider the term $1/x$ for $x \in [0, 1]$, which has finite variable bounds, but is unbounded. It is important to provide bounds for problem variables that guarantee that the problem functions are finitely-valued. If the user model does not include variable bounds that guarantee that all nonlinear expressions are finitely-valued, BARON will attempt to infer appropriate bounds from problem constraints. If this step fails, global optimality of the solutions provided is not guaranteed. Occasionally, because of the lack of bounds no numerically stable lower bounding problems can be constructed, in which case BARON may terminate.

See section [Some BARON features](#) on how to specify variable bounds.

5.6.2.2 Allowable nonlinear functions

In addition to multiplication and division, GAMS/BARON can handle nonlinear functions that involve $\exp(x)$, $\ln(x)$, x^α for real α , β^x for real β , x^y , and $|x|$. Currently, there is no support for other functions, including the trigonometric functions $\sin(x)$, $\cos(x)$, etc.

5.6.3 BARON output

5.6.3.1 BARON log output

The log output below is obtained for the MINLP model `gear.gms` from the GAMS model library using absolute and relative optimality tolerances of 1e-6.

=====

```

The solver first tests feasibility of the user-supplied starting point. This point is found to be feasible with an objective function value of 36.1767610000. BARON subsequently performs a randomized local search procedure and, eventually, finds a feasible solution with an objective of 4.23791612465. Then, the iteration log provides information every 1,000,000 branch-and-bound iterations and every 30 seconds. Additionally, information is printed at the end of the root node, whenever the value of the incumbent is improved by at least 10^{-5} , and at the end of the search. A star (*) in the first position of a line indicates that a better feasible solution was found that improves the value of previous best known solution by at least 10^{-5} . The log fields include the iteration number, number of open branch-and-bound nodes, the CPU time taken thus far, the lower bound, and the upper bound for the problem. The log output fields are summarized below:

Field	Description
Itn. no.	The number of the current iteration. A plus (+) following the iteration number denotes reporting while solving a probing (as opposed to a relaxation) subproblem of the corresponding node.
Open Nodes	Number of open nodes in branch-and-reduce tree.
Time	Current computational time in seconds. CPU time is reported for single-threaded jobs and wall clock time is reported for multi-threaded jobs.
Lower Bound	Current lower bound on the model.
Upper Bound	Current upper bound on the model.

Once the branch-and-reduce tree is searched, the best solution is isolated and a corresponding dual solution is calculated. Finally, the total number of branch-and-reduce iterations (number of search tree nodes) is reported, followed by the node where the best solution was identified (a -1 indicates preprocessing as explained in the next section on termination messages).

5.6.3.2 Termination messages, model and solver statuses

Upon normal termination, BARON will report the node where the optimal solution was found. We refer to this node as **nodeopt**. Associated with this node is a return code indicating the status of the solution found at **nodeopt**. The return code is given in the log line:

```

Best solution found at node: (return code)

```

The return codes have the following interpretation:

- 3 : no feasible solution found
- 2 : the best solution found was the user-supplied
- 1 : the best solution was found during preprocessing
- i : the best solution was found in the i-th node of the tree

In addition to reporting `nodeopt`, upon termination, BARON will issue one of the following statements:

*** Normal completion ***

This is the most desirable termination status. The problem has been solved within tolerances in this case. If BARON returns a code of -3, then no feasible solution exists.

*** Heuristic termination ***

While global optimality is not guaranteed in this case, BARON will terminate with this message when (a) a feasible solution has been found and (b) the progress of lower/upper bounds satisfies the heuristic termination criterion set by the user through BARON's [DeltaTerm](#) option.

*** User did not provide appropriate variable bounds ***

The user will need to read the BARON output (in file `sum.dat` in the scratch directory, use GAMS parameter `keep=1` to prevent the automatic removal of this directory) for pointers to variables and expressions with missing bounds. The model should be modified in order to provide bounds for variables and intermediate expressions that make it possible for BARON to construct reliable relaxations. Even though relaxation bounds are printed on the screen to give the user a feeling for convergence, these bounds may not be valid for the problem at hand. This message is followed by one of the following two messages:

***Infeasibility is therefore not guaranteed ***

This indicates that, because of missing bounds, no feasible solution was found, but model infeasibility was not proven.

*** Globality is therefore not guaranteed ***

This indicates that, because of missing bounds, a feasible solution was found, but global optimality was not proven.

*** Max. allowable nodes in memory reached ***

The user will need to increase the physical memory of the computer or change algorithmic options, such as branching and node selection rules, to reduce the size of the search tree and memory required for storage.

*** Max. allowable BaR iterations reached ***

The user will need to increase the maximum number of allowable iterations. The BARON option is [MaxIter](#). To specify this in GAMS, one can use the [NodLim](#) option. We remark that the BARON option [MaxIter](#) overrides [NodLim](#).

*** Max. allowable CPU time exceeded ***

The user will need to increase the maximum of allowable CPU time. The BARON option is [MaxTime](#). To specify this in GAMS, one can use the [ResLim](#) option. We remark that the BARON option [MaxTime](#) overrides [ResLim](#).

*** Problem is numerically sensitive ***

BARON is designed to automatically handle problems with numerical difficulties. However, for certain problems, the global optimum is numerically sensitive. This occurs, for instance, when the objective function value varies significantly over small neighborhoods of points that are strictly outside the feasible region but nonetheless feasible within numerical tolerances. When BARON returns this message, the "Best possible" reported on the objective is likely correct.

*** Search interrupted by user ***

The run was interrupted by the user (Ctrl-C).

*** Insufficient memory for data structures ***

More memory is needed to set up the problem data structures. The user will need to increase the physical memory available on the computer in order to accommodate problems of this size.

*** A potentially catastrophic access violation just took place ***

In the unlikely event of a memory access violation, BARON will terminate the search and return the best known solution. Please report problems that lead to this condition to Nick Sahinidis (niksah@minlp.com).

5.6.4 Some BARON features

The features described in this section rely on options that are further detailed in the next section. For details of the algorithmic implementations, the user may wish to consult publications cited at the end of this document.

5.6.4.1 No starting point is required

In contrast to many NLP algorithms that require a feasible starting point, a starting point is not required for BARON. A user may optionally provide a starting point for all or even some of the problem variables. BARON will judiciously initialize any variables that are not initialized by the user. Even when the problem functions cannot be evaluated at a user-provided starting point, BARON is still capable of carrying out its global search.

For problems for which GAMS compilation is aborted because the nonlinear functions cannot be evaluated at the starting point, the user can use the following commands before the `SOLVE` statement:

```
MaxExecError = 100000;
option sys12 = 1;
```

The first command asks GAMS to continue compilation for as many as `MaxExecError` execution errors. The `sys12` option will pass the model to the BARON despite the execution errors. Even though the starting point is bad in this case, BARON is capable of carrying out its global search.

5.6.4.2 Finding a few of the best or all feasible solutions

BARON offers a facility, through its `NumSol` option, to find the best few, or even all feasible, solutions to a model. The development of this facility was motivated by combinatorial optimization problems but the facility is applicable to continuous problems as well. Even for combinatorial problems, BARON does not rely on integer cuts to find multiple solutions. Instead, it utilizes a single search tree, thus providing a computationally efficient method for finding multiple solutions. Furthermore, because BARON's approach applies to integer as well as continuous programs, it can be used to find *all* feasible solutions to a system of nonlinear equality and inequality constraints.

Once a model is solved by BARON with the `NumSol` option, the solutions found can be recovered using the GAMS GDX facility. An example is provided below.

```
$eolcom !
$Ontext
  Purpose: demonstrate use of BARON option 'numsol' to obtain the best
  numsol solutions of an optimization problem in a single branch-and-bound
  search tree.

  The model solved here is a linear general integer problem with 18 feasible
  solutions. BARON is run with a request to find up to 20 solutions. The
  model solved is the same as the one solved in gamslib/icut.gms.

option decimals=8;

display xsol.1, zsol.1;

```

5.6.4.3 Using BARON as a multi-start heuristic solver

To gain insight into the difficulty of a nonlinear program, especially with regard to existence of multiple local solutions, modelers often make use of multiple local searches from randomly generated starting points. This can be easily done with BARON's [NumLoc](#) option, which determines the number of local searches to be done by BARON's preprocessor. BARON can be forced to terminate after preprocessing by setting the number of iterations to 0 through the [MaxIter](#) option. In addition to local search, BARON's preprocessor performs extensive reduction of variable ranges. To sample the search space for local minima without range reduction, one would have to set to 0 the range reduction options [TDo](#), [MDo](#), [LBTDo](#), and [OBTDo](#). On the other hand, leaving these options to their default values increases the likelihood of finding high quality local optima during preprocessing. If [NumLoc](#) is set to -1, local searches in preprocessing will be done from randomly generated starting points until global optimality is proved or [MaxTime](#) seconds have elapsed.

5.6.4.4 Systematic treatment of unbounded problems

If BARON declares a problem as unbounded, it will search for and may report a vertex and direction of an unbounded ray. In addition, BARON will report the best solution found. This will be a feasible point that is as far as possible along an unbounded ray while avoiding numerical errors due to floating point arithmetic.

5.6.4.5 Systematic treatment of infeasible problems

If BARON declares a problem as infeasible, it has the capability to identify a subset of the constraints that are infeasible and become feasible once any one of them is eliminated. This, so-called, *irreducibly inconsistent system* (IIS) can be obtained by BARON for all types of problems handled by BARON, including linear and nonlinear, continuous and integer, convex and nonconvex, and problems with complementarity constraints. BARON's [CompIIS](#) option can be used to identify an IIS.

As an example, consider the problem of minimizing the nonconvex function x_1x_3 over the following nonconvex constrained set:

$$\begin{aligned} e_1 : \quad & 85 + 0.006x_2x_5 + 0.0006x_1x_4 - 0.002x_3x_5 \leq 92 \\ e_2 : \quad & 0.8x_2x_5 + 0.003x_1x_2 + 0.002x_3^2 = 110 \\ e_3 : \quad & 9 + 0.005x_3x_5 + 0.001x_1x_3 + 0.002x_3x_4 \leq 25 \\ & 78 \leq x_1 \leq 102 \\ & 33 \leq x_2 \leq 45 \\ & 27 \leq x_i \leq 45, \quad i = 3, \dots, 5 \end{aligned}$$

When this problem is solved with [CompIIS](#) equal to 1, BARON provides the following result:

IIS contains 1 row and 3 columns as follows:

```
e2   Upper
x1   Lower
x2   Lower
x5   Lower
```

The IIS consists of the lower bounds of variables x_1 , x_2 , and x_5 , along with the $\leq$ part of the equality constraint e_2 . This suggests that constraint e_2 and the entire model can be made feasible by lowering the lower bound of any of the three variables that are part of the IIS, whereas modifying the bounds of x_3 would not make the model feasible.

If a problem is known to be infeasible and the user desires to identify an IIS, it may be beneficial to set BARON's [NumLoc](#) option to zero. Doing so will deactivate BARON's initial upper bounding search, which involves multiple local searches. On the other hand, [DoLocal](#) should be nonzero in order to permit local search during the solution of certain subproblems that BARON solves while searching for an IIS.

5.6.4.6 Handling of complementarity constraints

Complementarity relationships of the type $\mathbf{f}(\mathbf{x})\mathbf{g}(\mathbf{x}) = 0$ are automatically recognized and exploited algorithmically by BARON. The functions $\mathbf{f}$ and $\mathbf{g}$ may be univariate or multivariate, linear or nonlinear, convex or nonconvex, in terms of continuous and/or integer variables, and may be subject to additional constraints in the model. These complementarity relationships can be inferred by BARON even when implied by problem constraints and variable bounds. As a result, BARON can solve general mathematical programs with equilibrium constraints (MPECs). This class of problems includes the classical linear complementarity problem

(LCP): Find $z \geq 0$ and q such that

$$\begin{aligned} Mz + q &\geq 0, \\ z^t(Mz + q) &= 0 \end{aligned}$$

as well as the more general mixed complementarity problem

(MCP): Given a function $f : \mathbb{R}^n \rightarrow \mathbb{R}^n$ and bounds $l, u \in \mathbb{R}^n$ with $\overline{\mathbb{R}} = \mathbb{R} \cup \{-\infty, +\infty\}$, find $z \in \mathbb{R}^n$ and $w, v \in \mathbb{R}_+^n$ such that

$$\begin{aligned} f(z) &= w - v, \\ l &\leq z \leq u, \\ (z - l)^t w &= 0, \\ (u - z)^t v &= 0. \end{aligned}$$

Both problems are automatically recognized and exploited by BARON without the user having to mark complementarities in any special way. In GAMS, all these problems can be solved by BARON when declared as NLP or MINLP models.

5.6.4.7 Parallel capabilities

For difficult problems with integer variables, most of BARON's time is spent on solving MIP relaxations. Hence, considerable speedups may be obtained via parallel solution of the MIP subproblems. For this purpose, the option [threads](#) may be used to specify the number of cores that BARON's MIP subsolver is allowed to use. By default, this option has the value of 1, meaning that a single core will be utilized.

5.6.5 The BARON options

The BARON options allow the user to control termination tolerances, branching and relaxation strategies, heuristic local search options, and output options as detailed in this section.

Many options can also be set in the GAMS model. The most relevant GAMS options are [ResLim](#), [NodLim](#), [OptCA](#), [OptCR](#), [OptFile](#), and [CutOff](#). The [IterLim](#) option is not implemented. specify BARON iterations, the user can set the [MaxIter](#) option, which is equivalent to the GAMS option [NodLim](#).

Additionally, a BARON Options file can be provided. See section [The Solver Options File](#) for general use of solver option files.

For branching, users can specify separate branching priorities for any discrete and continuous variables using [Dot Options](#). To specify variable branching priorities, one specifies

$$(variable).prior(value)$$

in the BARON options file, where $(value)$ can be any non-negative real value. The lower the value, the higher the priority for branching, see also [Setting Priorities for Branching](#). Specifying `maxdouble` for $(value)$ translates to passing 0 as branching priority for $(variable)$.

5.6.5.1 Termination options

Option	Description	Default
AbsConFeasTol	Absolute constraint feasibility tolerance This tolerance is used for general constraints and variable bounds. AbsConFeasTol must be $\geq 1e-12$. A point is considered feasible for a constraint/bound if the absolute or relative constraint feasibility tolerance is satisfied. Range: $[1e-12, \infty]$	$1e-5$
AbsIntFeasTol	Absolute integer feasibility tolerance All integer variable values must satisfy this tolerance. AbsIntFeasTol must be $\geq 1e-12$. A point is considered integer feasible for a variable if integrality is satisfied using the absolute or relative integer feasibility tolerance. Range: $[1e-12, \infty]$	$1e-5$
BoxTol	Box elimination tolerance. Boxes will be eliminated if smaller than this tolerance. BoxTol must be $\geq 1e-12$.	$1e-8$
CutOff	Eliminate solutions that are no better than this value Can also be used with the GAMS model attribute option CutOff .	GAMS CutOff
DeltaA	Absolute improvement for insufficient progress termination DeltaA (δ_a) must be $\geq 1e-12$. Range: $[1e-12, \infty]$	∞
DeltaR	Relative improvement for insufficient progress termination DeltaR (δ_r) must be $\geq 1e-12$. Range: $[1e-12, \infty]$	1
DeltaT	Time interval for insufficient progress termination If DeltaTerm is set to 1, BARON will terminate if insufficient progress is made over DeltaT (δ_t) consecutive seconds. If δ_t is set to a non-positive quantity, BARON will automatically set δ_t equal to $-\delta_t$ times the CPU time taken till the end of root node processing. DeltaT can take any real value. Range: $[-\infty, \infty]$	-100
DeltaTerm	Indicates whether insufficient progress termination is on or off Users have the option to request BARON to terminate if insufficient progress is made over DeltaT (δ_t) consecutive seconds. Progress is measured using the absolute and relative improvement thresholds DeltaA (δ_a) and DeltaR (δ_r). Termination will occur if, over a period of δ_t consecutive seconds, the value of the best solution found by BARON is not improved by at least an absolute amount δ_a or an amount equal to δ_r times the value of the incumbent at time $t-\delta_t$. This termination condition is enforced after processing the root node and only after a feasible solution has been obtained. Because it relies on CPU time measurements, which may depend on machine load, this option may result in nondeterministic behavior. 0: do not enforce this termination condition 1: terminate if progress is insufficient	0
EpsA	Absolute termination tolerance. BARON terminates if $ U-L \leq \text{EpsA}$, where U and L are the upper and lower bound, respectively, on the optimal value of the optimization problem at the current iteration. EpsA must be $\geq 1e-12$.	GAMS OptCA
EpsR	Relative termination tolerance. BARON terminates if $ U-L \leq \text{EpsR} L $, where U and L are the upper and lower bound, respectively, on the optimal value of the optimization problem at the current iteration. EpsR must be ≥ 0 .	GAMS OptCR

Option	Description	Default
FirstFeas	Changes the search for first numsol solutions If set to 1, BARON will terminate once it finds NumSol feasible solutions, irrespective of solution quality. 0: search for the <i>best</i> NumSol feasible solutions 1: find NumSol solutions irrespective of solution quality	0
FirstLoc	Terminate the search as soon as a local optimum is found	0
ISolTol	Solution Distance Separation distance between solutions. This option is used in conjunction with NumSol . For combinatorial optimization problems, feasible solutions are isolated. For continuous problems, feasible solution points within an 1_∞ distance that does not exceed ISolTol will be treated as identical by BARON. ISolTol must be $\geq 1e-12$.	$1e-4$
MaxIter	Maximum number of branch-and-reduce iterations allowed Setting MaxIter to 0 will force BARON to terminate after root node preprocessing. Setting MaxIter to 1 will result in termination after the solution of the root node. MaxIter must be ≥ -1 , where -1 implies unlimited. Range: $[-1, \infty]$	GAMS NodeLim
MaxTime	Maximum time allowed (sec) MaxTime must be -1 or > 0 , where -1 implies unlimited. For single-threaded jobs, i.e., when threads equals 1, this limit is enforced on CPU time consumed by the job. For multi-threaded jobs, the limit is enforced on wall clock time.	GAMS ResLim
NumSol	Number of feasible solutions to be found Solutions found will be listed in the results file. As long as NumSol $\neq -1$, these solutions will be sorted from best to worse. If NumSol is set to -1, BARON will search for all feasible solutions to the given model and print them, in the order in which they are found, in the results file. NumSol must be ≥ -1 . Range: $[-1, \infty]$	1
RelConFeasTol	Relative constraint feasibility tolerance This tolerance is used for general constraints and variable bounds. RelConFeasTol must be ≥ 0 . A point is considered feasible for a constraint/bound if the absolute or relative constraint feasibility tolerance is satisfied. Range: $[0, 0.1]$	0
RelIntFeasTol	Relative integer feasibility tolerance All integer variable values must satisfy this tolerance. RelIntFeasTol must be ≥ 0 . A point is considered integer feasible for a variable if integrality is satisfied using the absolute or relative integer feasibility tolerance. Range: $[0, 0.1]$	0

5.6.5.2 Relaxation options

Option	Description	Default
Nouter1	Number of outer approximators of convex univariant functions NOuter1 must be ≥ 0 .	4
NoutIter	Number of rounds of cutting plane generation at node relaxation NOutIter must be ≥ 0 .	4
NoutPerVar	Number of outer approximations per variable for convex multivariate functions NOutPerVar must be ≥ 0 .	4

Option	Description	Default
OutGrid	Number of grid points per variable for convex multivariate approximators of BARON's CONVEX_EQUATIONS. OutGrid must be a ≥ 0 .	20
Threads	Number of cores used for solution of MIP subproblems The value of this option is passed to CBC, CPLEX, and XPRESS. Range: $[1, \infty]$	$\max(1, \text{GAMS Threads})$

5.6.5.3 Range reduction options

Option	Description	Default
LBTDDo	Linear-feasibility-based range reduction option (poor man's LPs) 0: no range reduction based on feasibility. 1: range reduction done based on feasibility.	1
MDDo	Marginals-based reduction option 0: no range reduction based on marginals. 1: range reduction done based on marginals.	1
OBTDDo	Optimality based tightening option 0: no range reduction based on optimality. 1: range reduction done based on optimality.	1
PDDo	Number of probing problems allowed -2: automatically decided by BARON. -1: probing on all variables. 0: no range reduction by probing. n: probing on n variables.	-2
TDDo	Nonlinear-feasibility-based range reduction option (poor man's NLPs) 0: no bounds tightening is performed. 1: bounds tightening is performed.	1

5.6.5.4 Tree management options

Option	Description	Default
BrPtStra	Branching point selection strategy 0: BARONs dynamic strategy 1: w-branching 2: bisection-branching 3: convex combination of 1 and 2	0
BrVarStra	Branching variable selection strategy 0: BARONs dynamic strategy 1: largest violation 2: longest edge	0
NodeSel	Specifies the node selection rule to be used for exploring the search tree Specifies the node selection rule to be used for exploring the search tree. 0: BARONs mixed selection scheme 1: best bound 2: last in first out [LIFO] 3: minimum infeasibility	0

5.6.5.5 Local search options

Option	Description	Default
DoLocal	Local search option for upper bounding 0: no local search is done during upper bounding 1: BARON's dynamic local search decision rule	1
NumLoc	Number of local searches done in preprocessing The first local search begins with the user-specified starting point. Subsequent local searches are done from judiciously chosen starting points. If NumLoc is set to -1, local searches in preprocessing will be done until proof of globality or MaxTime is reached. If NumLoc is set to -2, BARON decides the number of local searches in preprocessing based on problem and NLP solver characteristics. NumLoc must be ≥ -2 . Range: $[-2, \infty]$	-2

5.6.5.6 Output Options

Option	Description	Default
LocRes	Option to control output from local search 0: no local search output 1: detailed results from local search will be printed to res.dat file	0
prfreq	Log output frequency in number of nodes	1000000
prlevel	Defines the level of log output printed. 0: all log output is suppressed 1: print log output	1
prtimefreq	Log output frequency in number of seconds	30

5.6.5.7 Subsolver Options

Option	Description	Default
AllowExternal	Indicator for use of External NLP solver with automatic NLP solver selection In case of automatic NLP solver selection, this option can be used to selectively permit or disallow the use of external GAMS NLP solver as an NLP subsolver. 0: do not use the GAMS external NLP solver for local search 1: consider the GAMS external NLP solver for local search	1
AllowFilterSD	Indicator for use of FILTERSD with automatic NLP solver selection In case of automatic NLP solver selection, this option can be used to selectively permit or disallow the use of FILTERSD as an NLP subsolver. 0: do not use FILTERSD for local search 1: consider FILTERSD for local search	1
AllowFilterSQP	Indicator for use of FILTERSQP with automatic NLP solver selection In case of automatic NLP solver selection, this option can be used to selectively permit or disallow the use of FILTERSQP as an NLP subsolver. 0: do not use FILTERSQP for local search 1: consider FILTERSQP for local search	1

Option	Description	Default
AllowIpopt	Indicator for use of IPOPT with automatic NLP solver selection In case of automatic NLP solver selection, this option can be used to selectively permit or disallow the use of IPOPT as an NLP subsolver. Currently, this option defaults to 0 on Mac OS X. 0: do not use IPOPT for local search 1: consider IPOPT for local search	1
AllowMinos	Indicator for use of MINOS with automatic NLP solver selection In case of automatic NLP solver selection, this option can be used to selectively permit or disallow the use of MINOS as an NLP subsolver. 0: do not use MINOS for local search 1: consider MINOS for local search	1
AllowSnopt	Indicator for use of SNOPT with automatic NLP solver selection In case of automatic NLP solver selection, this option can be used to selectively permit or disallow the use of SNOPT as an NLP subsolver. 0: do not use SNOPT for local search 1: consider SNOPT for local search	1
ExtNLPsolver	External GAMS NLP solver and option file (e.g. conopt.1) Specifies the GAMS NLP solver to be used when NLPSol is set to 6. All GAMS NLP solvers are available through this option. If a non-existing solver is specified or the solver chosen cannot solve NLPs, NLPSol will be reset to its default. A GAMS solver options file can be specified for the GAMS NLP solver by adding a dot followed by the options file number to the solver name, e.g., setting <code>ExtNLPsolver</code> to <code>CONOPT.42</code> would instruct GAMS/CONOPT to use options file <code>conopt.o42</code> .	conopt
LPAlg	Specifies the LP algorithm to be used (available only with CPLEX as the LP solver) 0: automatic selection of LP algorithm 1: primal simplex 2: dual simplex 3: barrier	0
LPSol	Specifies the LP/MIP Solver to be used 3: CPLEX 7: XPRESS 8: CLP	3
NLPSol	Specifies the NLP solver to be used By default, BARON will select the NLP solver and may switch between different NLP solvers during the search, based on problem characteristics and solver performance. Any combination of licensed NLP solvers may be used in that case. A single specific NLP solver can be specified by setting this option to a value other than the default. If the specified solver is not licensed, BARON will default to automatic solver selection. -1: Automatic NLP solver selection and switching strategy 0: Local search based on function evaluations alone with no calls to local solvers 2: MINOS 4: SNOPT 6: GAMS NLP solver (see ExtNLPsolver) 9: IPOPT 10: FILTERSD 14: FILTERSQP	-1

5.6.5.8 Other Options

Option	Description	Default
CompIIS	Request the computation of an Irreducible Inconsistent Set (IIS) In case of an infeasible problem, this option can be used to search for an IIS. Setting this option 1, works very well for most problems. 0: do not search for an IIS 1: the search for an IIS is based on a fast heuristic 2: an IIS is obtained using a deletion filtering algorithm 3: an IIS is obtained using an addition filtering algorithm 4: an IIS is obtained using an addition-deletion filtering algorithm 5: an IIS is obtained using a depth-first search algorithm	0
IISInt	Indicates whether general integers should be considered as potential members of the IIS When search for an IIS is requested through CompIIS , BARON assumes that the model is unlikely to include an error in terms of binaries, i.e., the binary definitions are assumed correct and the IIS output should be interpreted with respect to binary definitions. General integer bounds may be assumed as correct or can be questioned using the option IISInt . Integrality is enforced in both cases. 0: do not consider general integers as part of an IIS, assume them to be correct 1: consider general integers (but not binaries) as part of an IIS	0
IISOrder	Order in which constraints are considered in the search for an IIS -1: auto set to aim for a small IIS depending on the value of CompIIS 1: arrange constraints in problem order 2: arrange constraints in ascending order of degree 3: arrange constraints in descending order of degree >3: random order using IISOrder as seed	-1
InfBnd	infinity value to be used on bounds If set to 0, then no bounds are used.	0
WantDual	whether to try hard to provide dual solution values 0: use an inexpensive way to solve the KKT system to provide dual values 1: make a final call to the NLP solver to compute dual values if the inexpensive way of solving the KKT system failed	1 for LP/RMIP, 0 otherwise

5.6.5.9 Interface and Conversion

Option	Description	Default
ClockType	Type of clock to use when reporting solving time back to GAMS wall : report time according to "clock on the wall" (as used by most GAMS solver links) cpu : report time used by CPU (summed up over all cores) baron : report same time as used by BARON ("cpu" if one thread, "wall" if multiple threads)	wall

Option	Description	Default
.EquClass	Equation Classification Specifies nature of named constraint in the users model. This is a Dot Option . Slices like <code>supply.EquClass("new-york") 1</code> are allowed. 0: Regular constraint. 1: Relaxation-only constraint. These constraints are provided to BARON as <code>RELAXATION_ONLY_EQUATIONS</code> and used to help strengthen the relaxation bound but are not considered as part of the user model and thus not used for feasibility testing of solutions or local search. Adding, for instance, the first-order optimality conditions as relaxation-only constraints often expedites convergence. 2: Convex constraint. These constraints are provided to BARON as <code>CONVEX_EQUATIONS</code> and used to generate cutting planes from the set of outer approximating supporting hyperplanes of the convex constraint set. 3: Convex constraint that is relaxation-only.	0
GDXOut	Prefix for GDX file names for multiple solutions if NumSol > 1.	

5.7 BDMLP

5.7.1 Introduction

GAMS/BDMLP is a LP and MIP solver that comes for free with any GAMS system. It is intended for small to medium sized models. GAMS/BDMLP was originally developed at the World Bank by T. Brooke, A. Drud, and A. Meeraus and is now maintained by GAMS Development Corp. The MIP part was added by M. Bussieck and A. Drud. GAMS/BDMLP runs on all platforms for which GAMS is available.

GAMS/BDMLP can solve reasonably sized LP models as long as the models are not very degenerate and are well scaled. The Branch-and-Bound algorithm for solving MIP is not in the same league as other commercial MIP codes that are hooked up to GAMS. Nevertheless, the MIP part of GAMS/BDMLP provides free access to a MIP solver that supports all of the discrete variable types supported by GAMS: Binary, Integer, Semicont, Semiint, Sos1, Sos2.

5.7.2 How to Run a Model with BDMLP

GAMS/BDMLP can solve models of the following types: LP, RMIP, and MIP. If you did not specify BDMLP as the default LP, RMIP, or MIP solver, use the following statement in your GAMS model before the solve statement:

```
option lp = bdmlp; { or RMIP or MIP }
```

5.8 BENCH

5.8.1 Introduction

BENCH is a GAMS solver to help facilitate benchmarking of GAMS optimization solvers. BENCH calls all user-specified GAMS solvers for a particular modeltype and captures results in the standard GAMS listing file format. BENCH can call the [GAMS/EXAMINER](#) solver automatically to independently verify feasibility and optimality of the solution returned.

There are several advantages to using the BENCH solver instead of just creating a GAMS model or batch file to do multiple solves with the various solvers. The first is that the model does not need to be generated individually for each solve; BENCH spawns each solver using the matrix file generated during the initial call to BENCH. Furthermore, BENCH simplifies solution examination/verification by automatically utilizing EXAMINER. And finally, data can automatically be collected for use with the PAVER performance analysis server.

BENCH comes free with any GAMS system. Licensing is dependent on licensing of the subsolvers. Thus, BENCH runs all solvers for which the user has a valid license.

5.8.1.1 How to run a Model with BENCH:

BENCH is run like any other GAMS solver. From the command line this is:

```
>> gams modelname modeltype=bench
```

where `modelname` is the GAMS model name and `modeltype` the solver indicator for a particular model type (e.g. LP, MIP, RMIP, QCP, MIQCP, RMIQCP, NLP, DNLP, CNS, MINLP, or MCP). BENCH can also be specified via the option statement within the model itself before the solve statement:

```
option modeltype=bench;
```

The user must *specify the solvers* to be included by using the `solvers` option (specified in a solver option file called `bench.opt`). Otherwise, GAMS/BENCH returns with a warning message

Warning: no solvers selected. Nothing to be done.

For more information on using solver option files and the `solvers` option, see Section [User-Specified Options](#).

5.8.2 User-Specified Options

5.8.2.1 GAMS Options

BENCH works like other GAMS solvers, and many options can be set in the GAMS model. The most relevant GAMS options are `nodlim`, `optca`, `optcr`, `optfile`, `cheat`, `cutoff`, `prioropt`, and `tryint`. These options are global in the sense that they are passed on to all subsolvers called.

The options can be set either through an option statement

```
option optfile=1;
```

or through a model suffix, which sets them only for an individual model

```
modelname.optfile=1;
```

All solver-related options are implemented in BENCH and are passed on to the respective solvers. We remark that for a particular subsolver some of these options may not be valid. In this case, although they are passed on by BENCH to the respective subsolver, they may not be used.

The options listed below differ from the usual implementation and are based on *individual limits* for each solver called by BENCH.

Option	Description	Default
iterlim	Sets the individual iteration limit . The subsolver called by BENCH will terminate and pass on the current solution if the number of iterations for each solver exceeds this limit.	2000000000
reslim	Sets the individual time limit in seconds. The subsolver called by BENCH will terminate and pass on the current solution if the resource time for each solver exceeds this limit.	1000

5.8.2.2 The BENCH Options

BENCH solver options are passed on through solver option files. If you specify `<modelname>.optfile = 1`; before the SOLVE statement in your GAMS model. BENCH will then look for and read an option file with the name `bench.opt` (see [The Solver Option File](#) for general use of solver option files). Unless explicitly specified in the BENCH option file, the solvers called by BENCH will not read option files. The syntax for the BENCH option file is

```
optname value
```

with one option on each line.

For example,

```
solvers conopt.1 minos snopt.2
```

This option determines the solvers to be called and is required. If the [solvers option](#) is omitted, then BENCH terminates with a warning message.

In this example, CONOPT will be called first with the option file `conopt.opt`. Then MINOS will be called with no option file and SNOPT will be called last with the option file `snopt.op2`. We note that the solvers are called in this order. This can be of particular use since detailed solution information at the end of the GAMS listing file is for the final solver called. The input of the solver option file is echoed in the listing file created by BENCH to help distinguish the different solver calls. See the [section describing the BENCH listing file](#) for details.

Specifying separate solver option files can also be useful to specify the subsolver that is to be used by a solver.

Option	Description	Default
allsolvers	Indicator whether all valid solvers for given modeltype should be run.	0
dualcstol	Tolerance on complementary slackness between dual variables and the primal constraints : passed to EXAMINER	1e-7
dualfeastol	Dual variables and constraints feasibility tolerance : passed to EXAMINER	1e-6
examiner	Indicator whether to call GAMS/EXAMINER to independently verify solution for feasibility and optimality.	0
outlev	Log output level. 1: BENCH summary log output only 2: BENCH summary log output and log output of each solver	2
paver	Indicator whether PAVER trace files should be written. Enabling causes a trace file <code>solver.pvr</code> to be written for each solver called. If the solver uses an option file, then the resulting file is <code>solver-optnum.pvr</code> , where optnum is the option file number. The files created can be submitted to the PAVER Server for automated performance analysis.	0

Option	Description	Default
paverex	Indicator whether PAVER trace files should be written for the Examiner run. Enabling causes a trace file <code>solver-ex.pvr</code> to be written for each solver called. If any Examiner check fails (independent or solver), then we return a model status 14 (no solution returned) and a solver status of 4 (terminated by solver). If no Examiner check is done, for example, because the return status is infeasible, then the status codes are returned as is. If the solver uses an option file, then the resulting file is <code>solver-optnum-ex.pvr</code> , where <code>optnum</code> is the option file number. The files created can be submitted to the PAVER Server for automated performance analysis.	0
primalcstol	Tolerance on complementary slackness between primal variables and the dual constraints: passed to EXAMINER	1e-7
primalfeastol	Primal variables and constraints feasibility tolerance: passed to EXAMINER	1e-6
returnlastsol	Indicator whether to return solution from the last solver	0
solvers	List of solvers to benchmark. <code>solver[.n]</code> gives the name of the GAMS solver that should be used, where <code>n</code> is the integer corresponding to the options file. If <code>.n</code> is missing, the solver will not look for an options file. This is a required option.	

5.8.3 Benchmark Analysis Using the PAVER Server

Benchmark data obtained using GAMS/BENCH can be automatically analyzed using the **PAVER Server**.

In order to enable creation of the necessary data files for submission to PAVER, users must enable the **paver** option.

For example, suppose a user has a set of models and wishes to compare three solvers, say CONOPT3, MINOS, and SNOPT. The user would then create a `bench.opt` solver option file with the entries

```
solvers conopt3 minos snopt
paver 1
```

Solving the models using `bench` as the solver will create PAVER data files, namely one for each solver: `conopt.pvr`, `minos.pvr`, and `snopt.pvr`, which can be submitted to the PAVER server at

http://www.gamsworld.org/performance/paver/pprocess_submit.htm

for automated analysis. Note that all PAVER trace files are appended to if they exist and if subsequent solves are made.

5.8.4 Solution Verification Using Examiner

5.8.4.1 Examiner Checks

BENCH can automatically call the [GAMS/EXAMINER](#) solver to check the solution for feasibility and complementarity. In particular, EXAMINER checks for

- primal feasibility: feasibility of both primal variables and primal constraints.
- dual feasibility: feasibility of both dual variables and dual constraints.
- primal complementary slackness: complementary slackness of primal variables to dual constraints.
- dual complementary slackness: complementary slackness of dual variables to primal constraints.

where EXAMINER does two types of checks:

- **Solvepoint:** the point returned by the solver. The solver returns both level and marginal values for the rows and columns: Examiner uses these exactly as given.
- **Solupoint:** EXAMINER uses the variable levels (primal variables) and equation marginals (dual variables) to compute the equation levels and variable marginals. The variable levels and equation marginals used are those returned by the subsolver.

By default, BENCH does not call EXAMINER to verify the solution. To enable solution verification, specify

```
examiner 1
```

in the `bench.opt` solver option file. Of interest are also the EXAMINER tolerances [dualcstol](#), [dualfeastol](#), [primalcstol](#), and [primalfeastol](#), which can also be set in the BENCH solver option file. For more information, see the [EXAMINER](#) documentation.

5.8.4.2 Examiner Output in BENCH

Examiner output, if solution verification is enabled, is given in the log output during the actual solve and summary information is given in the final BENCH summary under the **Examiner** column. Models either pass (P) or fail (F) based on the default Examiner or user-specified tolerances given. If EXAMINER does not do a check, for example, because the solver returns a model status of infeasible, then the **Examiner** column is given as (N).

If Examiner is not enabled, then n/a is listed under the **Examiner** column.

The first entry under **Examiner** is the Examiner status for using solver provided variable constraint level values (**solvepoint**). The second entry is the **solupoint**, where GAMS computes the constraint levels from the variable levels returned by the solver.

An example is given below, where we specified to use the solvers BDMLP, MINOS, XPRESS, and CPLEX on the GAMS Model Library model **trnsport**:

Solver	Modstat	Solstat	Objective	ResUsd	Examiner
BDMLP	1	1	153.6750	0.000	P/P
MINOS	1	1	153.6750	0.000	P/P
XPRESS	1	1	153.6750	0.040	P/P
CPLEX	1	1	153.6750	0.000	P/P

In the example below, EXAMINER is enabled, but does not perform any checks because the return status of the solver lists the model as infeasible (see the **Examiner** column (N/N)).

Solver	Modstat	Solstat	Objective	ResUsd	Examiner
BDMLP	5	1	0.0000	0.000	N/N

For models having discrete variables, for example MIP, MIQCP, or MINLP, we also show the best bound. A sample output using the GAMS model library model **magic** is shown below.

Solver	Modstat	Solstat	Objective	BestBound	ResUsd	Examiner
CPLEX	8	1	991970.0000	985514.2857	0.000	n/a
XPRESS	1	1	988540.0000	988540.0000	0.060	n/a
MOSEK	8	1	988540.0000	988540.0000	0.170	n/a

5.8.5 Output

5.8.5.1 The BENCH Log File

The BENCH log output contains complete log information for each solver called. The individual solver calls are indicated by the entry

```
--- Spawning solver : (Solver Name)
```

followed by the log output of the individual solver.

An example of the log output using the transportation model **trnsport**) from the GAMS model library. We specify the solvers BDMLP, XPRESS, MINOS and CPLEX via the option file **bench.opt**:

5.8.5.2 The BENCH Listing File

The BENCH listing file is similar to the standard GAMS format. It contains a benchmark summary of all solvers called. The regular solve summary for BENCH does not return a solution (although the solution of the final solve can be returned using the [returnlastsol option](#)). For the example below we use the `batchdes` model from the GAMS model library using the solvers SBB and DICOPT. We specify the two solvers using a `bench.opt` option file with the entry:

```
solvers sbb.1 dicopt
```

Note that SBB will use a solver option file called `sbb.opt`.

```

      S O L V E      S U M M A R Y

MODEL  batch          OBJECTIVE cost
TYPE   MINLP          DIRECTION MINIMIZE
SOLVER BENCH          FROM LINE 183

**** SOLVER STATUS      1 NORMAL COMPLETION
**** MODEL STATUS      14 NO SOLUTION RETURNED
**** OBJECTIVE VALUE          0.0000

RESOURCE USAGE, LIMIT      0.000      1000.000
ITERATION COUNT, LIMIT      0      10000
Reading user supplied options file /home/models/bench.opt
Processing...
> solvers sbb.1 dicopt

```

Note that the model status return code for BENCH itself is always SOLVER STATUS 1 and MODEL STATUS 14, since BENCH itself does not return a solution by default. To obtain the status codes and solution information of the last solver, the [returnlastsol option](#) can be enabled.

In addition the listing file contains complete solve summary information for each solver called. Also, note that the option file used for SBB and its contents are echoed to the SBB summary.

```

      B E N C H M A R K      S U M M A R Y

SOLVER      SBB
SOLVER STATUS  1 NORMAL COMPLETION
MODEL STATUS   8 INTEGER SOLUTION
OBJECTIVE VALUE      167427.6571
RESOURCE USAGE, LIMIT      0.080      1000.000
ITERATION COUNT, LIMIT      139      100000
EVALUATION ERRORS, LIMIT      0      0
OPTION FILE      sbb.opt

Reading user supplied options file sbb.opt
Processing...
> rootsolver conopt2
> subsolver snopt

```

```

SOLVER      DICOPT
SOLVER STATUS  1 NORMAL COMPLETION
MODEL STATUS   8 INTEGER SOLUTION
OBJECTIVE VALUE      167427.6571
RESOURCE USAGE, LIMIT      0.100      999.920
ITERATION COUNT, LIMIT      117      99861
EVALUATION ERRORS, LIMIT      0      0

```

Note that the listing file does not contain detailed solution information since BENCH does not return any values.

5.8.6 Interrupting BENCH with Ctrl-C

BENCH passes all `Control-C` (Ctrl-C) signals to the respective subsolvers. If a terminate signal via Ctrl-C is sent in the middle of a solver run (i.e. not initially when the solver begins execution), the individual subsolver is terminated.

To terminate not only the subsolver but also BENCH, a Ctrl-C signal should be sent at the beginning of a solver's execution. Thus, several Ctrl-C in rapid succession will terminate BENCH.

Benchmark summary information will be written to the listing file for each solver that has successfully completed without any signal interrupt.

5.8.7 Benchmark Example

In this section we will give a small example showing how to use the BENCH solver and automate the subsequent analysis using the [PAVER Server](#). In particular, we will run the three versions of CONOPT (CONOPT1, CONOPT2, and CONOPT3, as well as CONOPT3 with no scaling) on the default instance of the COPS models for nonlinear programming. We will use the 17 models available from the GAMS Model Library.

First we need to extract all of the models from the GAMS Model Library. We can create a file which will extract these automatically. Create a file called `getcops.gms` with the entries below:

```
$call gamslib camshape
$call gamslib catmix
$call gamslib chain
$call gamslib elec
$call gamslib flowchan
$call gamslib gasoil
$call gamslib glider
$call gamslib jbearing
$call gamslib lnts
$call gamslib methanol
$call gamslib minsurf
$call gamslib pinene
$call gamslib polygon
$call gamslib popdynm
$call gamslib robot
$call gamslib rocket
$call gamslib torsion
```

Running the file using `gams getcops.gms` extracts the models. Then create a BENCH solver option file called `bench.opt` with the entries

```
solvers conopt1 conopt2 conopt3 conopt3.1
paver 1
```

The first entry tells BENCH to run the solvers CONOPT1, CONOPT2, and CONOPT3 and then CONOPT3 with the option file `conopt3.opt`. The second entry tells BENCH to create PAVER trace files. These can be submitted to the [PAVER server](#) for automated performance analysis. Now create an option file `conopt3.opt` with the entry

```
lsscal f
```

which tells CONOPT3 not to use scaling.

We can now run the models in batch mode, for example by creating a GAMS batch file `runcops.gms` with the following entries:

```
$call gams camshape.gms nlp=bench optfile=1 reslim=10 domlim=99999
$call gams catmix.gms   nlp=bench optfile=1 reslim=10 domlim=99999
$call gams chain.gms    nlp=bench optfile=1 reslim=10 domlim=99999
$call gams elec.gms     nlp=bench optfile=1 reslim=10 domlim=99999
$call gams flowchan.gms nlp=bench optfile=1 reslim=10 domlim=99999
$call gams gasoil.gms   nlp=bench optfile=1 reslim=10 domlim=99999
$call gams glider.gms   nlp=bench optfile=1 reslim=10 domlim=99999
$call gams jbearing.gms nlp=bench optfile=1 reslim=10 domlim=99999
$call gams lnts.gms     nlp=bench optfile=1 reslim=10 domlim=99999
$call gams methanol.gms nlp=bench optfile=1 reslim=10 domlim=99999
$call gams minsurf.gms  nlp=bench optfile=1 reslim=10 domlim=99999
$call gams pinene.gms   nlp=bench optfile=1 reslim=10 domlim=99999
$call gams polygon.gms  nlp=bench optfile=1 reslim=10 domlim=99999
$call gams popdynm.gms  nlp=bench optfile=1 reslim=10 domlim=99999
$call gams robot.gms    nlp=bench optfile=1 reslim=10 domlim=99999
$call gams rocket.gms   nlp=bench optfile=1 reslim=10 domlim=99999
$call gams torsion.gms  nlp=bench optfile=1 reslim=10 domlim=99999
```

Running the file using the command `gams runcops.gms` runs all models with all three solvers through the GAMS/BENCH solver. Furthermore, three PAVER trace files are created: `conopt1.pvr`, `conopt2.pvr`, `conopt3.pvr` and `conopt3-1.pvr`, where the latter is for CONOPT3 with no scaling. Users can then submit the three trace files to the PAVER Server for automated analysis.

The resulting performance plot in the following figure shows the efficiency of each solver/solver option.

5.9 BONMIN and BONMINH

5.9.1 Introduction

COIN-OR BONMIN (**B**asic **O**pen-source **N**onlinear **M**ixed **I**nteger programming) is an open-source solver for mixed-integer nonlinear programming (MINLPs), implementing branch-and-bound, branch-and-cut, and outer approximation algorithms. The code has been developed as part of a collaboration between Carnegie Mellon University and IBM Research. The COIN-OR project leader for BONMIN is Pierre Bonami.

BONMIN can handle mixed-integer nonlinear programming models which functions should be twice continuously differentiable. The BONMIN link in GAMS supports continuous, binary, and integer variables, special ordered sets, branching priorities, but no semi-continuous or semi-integer variables.

BONMIN implements six different algorithms for solving MINLPs:

- **B-BB (default)**: a simple branch-and-bound algorithm based on solving a continuous nonlinear program at each node of the search tree and branching on integer variables [122] ; this algorithm is similar to the one implemented in the solver **SBB**
- **B-OA**: an outer-approximation based decomposition algorithm based on iterating solving and improving of a MIP relaxation and solving NLP subproblems [74] [89] ; this algorithm is similar to the one implemented in the solver **DICOPT**
- **B-QG**: an outer-approximation based branch-and-cut algorithm based on solving a continuous linear program at each node of the search tree, improving the linear program by outer approximation, and branching on integer variables [195] .
- **B-Hyb**: a branch-and-bound algorithm which is a hybrid of B-BB and B-QG and is based on solving either a continuous nonlinear or a continuous linear program at each node of the search tree, improving the linear program by outer approximation, and branching on integer variables [46]
- **B-ECP**: a Kelley's outer-approximation based branch-and-cut algorithm inspired by the settings used in the solver **FilMINT** [1]
- **B-iFP**: an iterated feasibility pump algorithm [47]

The algorithms are exact when the problem is *convex*, otherwise they are heuristics.

For convex MINLPs, experiments on a reasonably large test set of problems have shown that B-Hyb is the algorithm of choice (it solved most of the problems in 3 hours of computing time). Nevertheless, there are cases where B-OA (especially when used with CPLEX as MIP subproblem solver) is much faster than B-Hyb and others where B-BB is interesting. B-QG and B-ECP corresponds mainly to a specific parameter setting of B-Hyb but they can be faster in some cases. B-iFP is more tailored at finding quickly good solutions to very hard convex MINLP. For *nonconvex* MINLPs, it is strongly recommended to use B-BB (the outer-approximation algorithms have not been tailored to treat nonconvex problems). Although even B-BB is only a heuristic for such problems, [several options are available](#) to try and improve the quality of the solutions it provides.

NLPs are solved in BONMIN by **IPOPT** and **IPOPTH**, which can use MUMPS [14] [15] (currently the default) or MKL PARDISO [218] [219] (only Linux and Windows) as linear solver. In the commercially licensed GAMS/BONMINH version, also the linear solvers MA27, MA57, HSL_MA86, and HSL_MA97 from the Harwell Subroutines Library (HSL) are available in IPOPT. In this case, the default linear solver in IPOPT is MA27.

For more information on BONMIN we refer to [47] [44] [48] [46] and the [BONMIN web site](#). Most of the BONMIN documentation in this section is taken from the BONMIN manual [45] .

5.9.2 Usage

The following statement can be used inside your GAMS program to specify using BONMIN:

```
Option MINLP = BONMIN;    { or Option MIQCP = BONMIN; }
```

This statement should appear before the `Solve` statement. If BONMIN was specified as the default solver during GAMS installation, the above statement is not necessary.

To use BONMINH, one should use the statement

```
Option MINLP = BONMINH;  { or Option MIQCP = BONMINH; }
```

GAMS/BONMIN currently does not support the GAMS Branch-and-Cut-and-Heuristic (BCH) Facility. If you need to use GAMS/BONMIN with BCH, please consider to use a [GAMS system of version ≤ 23.3](#).

5.9.2.1 Specification of Options

A BONMIN options file contains both IPOPT and BONMIN options, for clarity all BONMIN options should be preceded with the prefix `bonmin..`. The scheme to [name option files](#) is the same as for all other GAMS solvers. The format of the option file is [the same as for IPOPT](#).

The most important option in BONMIN is the choice of the solution algorithm. This can be set by using the option named [algorithm](#) which can be set to B-BB, B-OA, B-QG, B-Hyb, B-ECP, or B-iFP (its default value is B-BB). Depending on the value of this option, certain other options may be available or not, cf. Section [List of all BONMIN Options](#).

An example of a `bonmin.opt` file is the following:

```
bonmin.algorithm      B-Hyb
bonmin.oa_log_level   4
print_level           6
```

This sets the algorithm to be used to the hybrid algorithm, the level of outer approximation related output to 4, and sets the print level for IPOPT to 6.

GAMS/BONMIN understands currently the following GAMS parameters: [reslim](#) (time limit), [iterlim](#) (iteration limit), [nodlim](#) (node limit), [cutoff](#), [optca](#) (absolute gap tolerance), and [optcr](#) (relative gap tolerance). Further, the option [threads](#) can be used to control the number of threads used in the [linear algebra routines of IPOPT](#) and [MIP solves of CPLEX](#).

5.9.2.2 Passing options to local search based heuristics and OA generators

Several parts of the algorithms in BONMIN are based on solving a simplified version of the problem with another instance of BONMIN: Outer Approximation Decomposition (called in B-Hyb at the root node) and Feasibility Pump for MINLP (called in B-Hyb or B-BB at the root node), RINS, RENS, Local Branching.

In all these cases, one can pass options to the sub-algorithm used through the option file. The basic principle is that the `bonmin.` prefix is replaced with a prefix that identifies the sub-algorithm used:

- `oa.decomposition.` to pass options to Outer Approximation Decomposition,
- `pump_for_minlp.` to pass options to Feasibility Pump for MINLP,
- `rins.` to pass options to RINS,
- `rens.` to pass options to RENS,
- `local_branch.` to pass options to Local Branching.

For example, to run a maximum of 60 seconds of feasibility pump (FP) for MINLP until 6 solutions are found at the beginning of the hybrid algorithm, one sets the following options:

```
bonmin.algorithm      B-Hyb
bonmin.pump_for_minlp yes # tells to run FP for MINLP
pump_for_minlp.time_limit 60 # set a time limit for the pump
pump_for_minlp.solution_limit 6 # set a solution limit
```

Note that the actual solution and time limit will be the minimum of the global limits set for BONMIN.

A slightly more complicated set of options may be used when using RINS. Say for example that one wants to run RINS inside B-BB. Each time RINS is called one wants to solve the small-size MINLP generated using B-QG (one may run any algorithm available in BONMIN for solving an MINLP) and wants to stop as soon as B-QG found one solution. To achieve this, one sets the following options

```
bonmin.algorithm      B-BB
bonmin.heuristic_rins yes
rins.algorithm         B-QG
rins.solution_limit    1
```

This example shows that it is possible to set any option used in the sub-algorithm to be different than the one used for the main algorithm.

In the context of outer-approximation (OA) and feasibility pump for MINLP, a standard MILP solver is used. Several options are available for configuring this MILP solver. BONMIN allows a choice of different MILP solvers through the option `milp_solver`. Values for this option are: `Cbc_D`, which uses CBC with its default settings, `Cbc_Par`, which uses a version of CBC that can be parameterized by the user, and `Cplex`, which uses CPLEX with its default settings. The options that can be set in `Cbc_Par` are the number of strong-branching candidates, the number of branches before pseudo costs are to be trusted, and the frequency of the various cut generators, cf. Section [List of all BONMIN Options](#) for details. To use the `Cplex` option, a valid CPLEX licence (standalone or GAMS/CPLEX) is required.

5.9.2.3 Getting good solutions to nonconvex problems

To solve a problem with nonconvex constraints, one should only use the branch-and-bound algorithm B-BB.

A few options have been designed in BONMIN specifically to treat problems that do not have a convex continuous relaxation. In such problems, the solutions obtained from IPOPT are not necessarily globally optimal, but are only locally optimal. Also the outer-approximation constraints are not necessarily valid inequalities for the problem. No specific heuristic method for treating nonconvex problems is implemented within the OA framework. But for the pure branch-and-bound B-BB, a few options have been implemented while having in mind that lower bounds provided by IPOPT should not be trusted and with the goal of trying to get good solutions. Such options are at an experimental stage.

First, in the context of nonconvex problems, IPOPT may find different local optima when started from different starting points. The two options [num_resolve_at_root](#) and [num_resolve_at_node](#) allow for solving the root node or each node of the tree, respectively, with a user-specified number of different randomly-chosen starting points, saving the best solution found. Note that the function to generate a random starting point is very naïve: it chooses a random point (uniformly) between the bounds provided for the variable. In particular if there are some functions that can not be evaluated at some points of the domain, it may pick such points, and so it is not robust in that respect.

Secondly, since the solution given by IPOPT does not truly give a lower bound, the fathoming rule can be changed to continue branching even if the solution value to the current node is worse than the best-known solution. This is achieved by setting [allowable_gap](#), [allowable_fraction_gap](#), and [cutoff_decr](#) to negative values.

5.9.2.4 IPOPT options changed by BONMIN

IPOPT has a very large number of options, see Section [List of IPOPT Options](#) to get a complete description. To use IPOPT more efficiently in the context of MINLP, BONMIN changes some IPOPT options from their default values, which may help to improve IPOPT's warm-starting capabilities and its ability to prove quickly that a subproblem is infeasible. These are settings that IPOPT does not use for ordinary NLP problems. Note that options set by the user in an option file will override these settings.

- [mu_strategy](#) and [mu_oracle](#) are set, respectively, to **adaptive** and **probing** by default. These are strategies in IPOPT for updating the barrier parameter. They were found to be more efficient in the context of MINLP.
- [gamma_phi](#) and [gamma_theta](#) are set to 1E-8 and 1E-4, respectively. This has the effect of reducing the size of the filter in the line search performed by IPOPT.
- [required_infeasibility_reduction](#) is set to 0.1. This increases the required infeasibility reduction when IPOPT enters the restoration phase and should thus help to detect infeasible problems faster.
- [expect_infeasible_problem](#) is set to **yes**, which enables some heuristics to detect infeasible problems faster.
- [warm_start_init_point](#) is set to **yes** when a full primal/dual starting point is available (generally for all the optimizations after the continuous relaxation has been solved).
- [print_level](#) is set to 0 by default to turn off IPOPT output (except for the root node, which print level is controlled by the BONMIN option [nlp_log_at_root](#)).
- [bound_relax_factor](#) is set to 1E-10. All of the bounds of the problem are relaxed by this factor. This may cause some trouble when constraint functions can only be evaluated within their bounds. In such cases, this option should be set to 0.

5.9.3 List of all BONMIN Options

The following tables give lists of all options together with their types, default values, and availability in each of the main algorithms. The column labeled **Cbc.Par** indicates the options that can be used to parametrize the MILP subsolver in the context of OA and FP.

5.9.3.1 Algorithm choice

ma97_umax	$\mathbb{Q}$	0.0001

5.9.3.28 Ipopt Mumps Linear Solver

Option	Type	Default
mumps_dep_tol	$\mathbb{Q}$	0
mumps_mem_percent	$\mathbb{Z}$	1000
mumps_permuting_scaling	$\mathbb{Z}$	7
mumps_pivot_order	$\mathbb{Z}$	7
mumps_pivtol	$\mathbb{Q}$	10^{-6}
mumps_pivtolmax	$\mathbb{Q}$	0.1
mumps_scaling	$\mathbb{Z}$	77

5.9.3.29 Ipopt NLP

Option	Type	Default
bound_relax_factor	$\mathbb{Q}$	10^{-8}
check_derivatives_for_naninf	string	no
dependency_detection_with_rhs	string	no
dependency_detector	string	none
fixed_variable_treatment	string	make_parameter
honor_original_bounds	string	yes
jac_c_constant	string	no
jac_d_constant	string	no
kappa_d	$\mathbb{Q}$	10^{-5}

5.9.3.30 Ipopt NLP Scaling

Option	Type	Default
nlp_scaling_constr_target_gradient	$\mathbb{Q}$	0
nlp_scaling_max_gradient	$\mathbb{Q}$	100
nlp_scaling_method	string	gradient-based
nlp_scaling_min_value	$\mathbb{Q}$	10^{-8}
nlp_scaling_obj_target_gradient	$\mathbb{Q}$	0

5.9.3.31 Ipopt Output

Option	Type	Default
inf_pr_output	string	original
print_eval_error	string	yes
print_frequency_iter	$\mathbb{Z}$	1
print_frequency_time	$\mathbb{Q}$	0
print_info_string	string	no
print_level	$\mathbb{Z}$	5
print_timing_statistics	string	no
replace_bounds	string	no

5.9.3.32 Ipopt Pardiso Linear Solver

Option	Type	Default
pardiso_matching_strategy	string	complete+2x2
pardiso_max_iterative_refinement_steps	$\mathbb{Z}$	1
pardiso_msglvl	$\mathbb{Z}$	0
pardiso_order	string	metis
pardiso_redo_symbolic_fact_only_if_inertia_wrong	string	no
pardiso_repeated_perturbation_means_singular	string	no
pardiso_skip_inertia_check	string	no

5.9.3.33 Ipopt Restoration Phase

Option	Type	Default
bound_mult_reset_threshold	$\mathbb{Q}$	1000
constr_mult_reset_threshold	$\mathbb{Q}$	0
evaluate_orig_obj_at_resto_trial	string	yes
expect_infeasible_problem	string	no
expect_infeasible_problem_ctol	$\mathbb{Q}$	0.001
expect_infeasible_problem_ytol	$\mathbb{Q}$	10^8
max_resto_iter	$\mathbb{Z}$	3000000
max_soft_resto_iters	$\mathbb{Z}$	10
required_infeasibility_reduction	$\mathbb{Q}$	0.9
resto_failure_feasibility_threshold	$\mathbb{Q}$	0
resto_penalty_parameter	$\mathbb{Q}$	1000

Option	Type	Default
resto_proximity_weight	$\mathbb{Q}$	1
soft_resto_perror_reduction_factor	$\mathbb{Q}$	0.9999
start_with_resto	string	no

5.9.3.34 Ipopt Step Calculation

Option	Type	Default
fast_step_computation	string	no
first_hessian_perturbation	$\mathbb{Q}$	0.0001
jacobian_regularization_exponent	$\mathbb{Q}$	0.25
jacobian_regularization_value	$\mathbb{Q}$	10^{-8}
max_hessian_perturbation	$\mathbb{Q}$	10^{20}
max_refinement_steps	$\mathbb{Z}$	10
mehrotra_algorithm	string	no
min_hessian_perturbation	$\mathbb{Q}$	10^{-20}
min_refinement_steps	$\mathbb{Z}$	1
neg_curv_test_reg	string	yes
neg_curv_test_tol	$\mathbb{Q}$	0
perturb_always_cd	string	no
perturb_dec_fact	$\mathbb{Q}$	0.333333
perturb_inc_fact	$\mathbb{Q}$	8
perturb_inc_fact_first	$\mathbb{Q}$	100
residual_improvement_factor	$\mathbb{Q}$	1
residual_ratio_max	$\mathbb{Q}$	10^{-10}
residual_ratio_singular	$\mathbb{Q}$	10^{-5}

5.9.3.35 Ipopt Warm Start

Option	Type	Default
warm_start_bound_frac	$\mathbb{Q}$	0.001
warm_start_bound_push	$\mathbb{Q}$	0.001
warm_start_init_point	string	no
warm_start_mult_bound_push	$\mathbb{Q}$	0.001

Option	Type	Default
warm_start_mult_init_max	Q	10^6
warm_start_slack_bound_frac	Q	0.001
warm_start_slack_bound_push	Q	0.001

5.9.4 Detailed Options Description

In the following we give a detailed description of all BONMIN options.

2mir_cuts (*integer*): Frequency (in terms of nodes) for generating 2-MIR cuts in branch-and-cut [↔](#)

If $k > 0$, cuts are generated every k nodes, if $-99 < k < 0$ cuts are generated every $-k$ nodes but Cbc may decide to stop generating cuts, if not enough are generated at the root node, if $k = -99$ generate cuts only at the root node, if $k = 0$ or 100 do not generate cuts.

Range: $[-100, \infty]$

Default: 0

acceptable_compl_inf_tol (*real*): 'Acceptance' threshold for the complementarity conditions. [↔](#)

Absolute tolerance on the complementarity. "Acceptable" termination requires that the max-norm of the (unscaled) complementarity is less than this threshold; see also `acceptable_tol`.

Default: 0.01

acceptable_constr_viol_tol (*real*): 'Acceptance' threshold for the constraint violation. [↔](#)

Absolute tolerance on the constraint violation. "Acceptable" termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold; see also `acceptable_tol`.

Default: 0.01

acceptable_dual_inf_tol (*real*): 'Acceptance' threshold for the dual infeasibility. [↔](#)

Absolute tolerance on the dual infeasibility. "Acceptable" termination requires that the (max-norm of the unscaled) dual infeasibility is less than this threshold; see also `acceptable_tol`.

Default: $1e+10$

acceptable_iter (*integer*): Number of 'acceptable' iterates before triggering termination. [↔](#)

If the algorithm encounters this many successive "acceptable" iterates (see "acceptable_tol"), it terminates, assuming that the problem has been solved to best possible accuracy given round-off. If it is set to zero, this heuristic is disabled.

Default: 15

acceptable_obj_change_tol (*real*): 'Acceptance' stopping criterion based on objective function change. [↔](#)

If the relative change of the objective function (scaled by $\text{Max}(1, |f(x)|)$) is less than this value, this part of the acceptable tolerance termination is satisfied; see also `acceptable_tol`. This is useful for the quasi-Newton option, which has trouble to bring down the dual infeasibility.

Default: $1e+20$

acceptable_tol (*real*): 'Acceptable' convergence tolerance (relative). ↩

Determines which (scaled) overall optimality error is considered to be "acceptable." There are two levels of termination criteria. If the usual "desired" tolerances (see `tol`, `dual_inf_tol` etc) are satisfied at an iteration, the algorithm immediately terminates with a success message. On the other hand, if the algorithm encounters "acceptable_iter" many iterations in a row that are considered "acceptable", it will terminate before the desired convergence tolerance is met. This is useful in cases where the algorithm might not be able to achieve the "desired" level of accuracy.

Default: `1e-06`

accept_after_max_steps (*integer*): Accept a trial point after maximal this number of steps. ↩

Even if it does not satisfy line search conditions.

Range: $[-1, \infty]$

Default: `-1`

accept_every_trial_step (*string*): Always accept the first trial step. ↩

Setting this option to "yes" essentially disables the line search and makes the algorithm take aggressive steps, without global convergence guarantees.

Default: `no`

value	meaning
<code>no</code>	don't arbitrarily accept the full step
<code>yes</code>	always accept the full step

adaptive_mu_globalization (*string*): Globalization strategy for the adaptive mu selection mode. ↩

To achieve global convergence of the adaptive version, the algorithm has to switch to the monotone mode (Fiacco-McCormick approach) when convergence does not seem to appear. This option sets the criterion used to decide when to do this switch. (Only used if option "mu_strategy" is chosen as "adaptive".)

Default: `obj-constr-filter`

value	meaning
<code>kkt-error</code>	nonmonotone decrease of kkt-error
<code>never-monotone-mode</code>	disables globalization
<code>obj-constr-filter</code>	2-dim filter for objective and constraint violation

adaptive_mu_kkterror_red_fact (*real*): Sufficient decrease factor for 'kkt-error' globalization strategy. ↩

For the "kkt-error" based globalization strategy, the error must decrease by this factor to be deemed sufficient decrease.

Range: $[0, 1]$

Default: `0.9999`

adaptive_mu_kkterror_red_iters (*integer*): Maximum number of iterations requiring sufficient progress. [↔](#)

For the "kkt-error" based globalization strategy, sufficient progress must be made for "adaptive_mu_kkterror_red_iters" iterations. If this number of iterations is exceeded, the globalization strategy switches to the monotone mode.

Default: 4

adaptive_mu_kkt_norm_type (*string*): Norm used for the KKT error in the adaptive mu globalization strategies. [↔](#)

When computing the KKT error for the globalization strategies, the norm to be used is specified with this option. Note, this options is also used in the QualityFunctionMuOracle.

Default: 2-norm-squared

value	meaning
1-norm	use the 1-norm (abs sum)
2-norm	use 2-norm
2-norm-squared	use the 2-norm squared (sum of squares)
max-norm	use the infinity norm (max)

adaptive_mu_monotone_init_factor (*real*): Determines the initial value of the barrier parameter when switching to the monotone mode. [↔](#)

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode and fixed_mu_oracle is chosen as "average_compl", the barrier parameter is set to the current average complementarity times the value of "adaptive_mu_monotone_init_factor".

Default: 0.8

adaptive_mu_restore_previous_iterate (*string*): Indicates if the previous iterate should be restored if the monotone mode is entered. [↔](#)

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode, it can either start from the most recent iterate (no), or from the last iterate that was accepted (yes).

Default: no

value	meaning
no	don't restore accepted iterate
yes	restore accepted iterate

add_only_violated_oa (*string*): Do we add all OA cuts or only the ones violated by current point? [↔](#)

Default: no

value	meaning
no	Add all cuts
yes	Add only violated cuts

algorithm (*string*): Choice of the algorithm. [↩](#)

This will preset some of the options of bonmin depending on the algorithm choice.

Default: B-BB

value	meaning
b-bb	simple branch-and-bound algorithm,
b-ecp	ECP cuts based branch-and-cut a la FilMINT.
b-hyb	hybrid outer approximation based branch-and-cut,
b-ifp	Iterated Feasibility Pump for MINLP.
b-oa	OA Decomposition algorithm,
b-qg	Quesada and Grossmann branch-and-cut algorithm,

allowable_fraction_gap (*real*): Specify the value of relative gap under which the algorithm stops. [↩](#)

Stop the tree search when the gap between the objective value of the best known solution and the best bound on the objective of any solution is less than this fraction of the absolute value of the best known solution value.

Range: $[-\infty, \infty]$

Default: 0.1

allowable_gap (*real*): Specify the value of absolute gap under which the algorithm stops. [↩](#)

Stop the tree search when the gap between the objective value of the best known solution and the best bound on the objective of any solution is less than this.

Range: $[-\infty, \infty]$

Default: 0

alpha_for_y (*string*): Method to determine the step size for constraint multipliers. [↩](#)

This option determines how the step size (alpha.y) will be calculated when updating the constraint multipliers.

Default: primal

value	meaning
acceptor	Call LSAccepter to get step size for y
bound-mult	use step size for the bound multipliers (good for LPs)
dual-and-full	use the dual step size, and full step if $\delta_x \leq \alpha_{\text{for\_y\_tol}}$
full	take a full step of size one
max	use the max of primal and bound multipliers
min	use the min of primal and bound multipliers
min-dual-infeas	choose step size minimizing new dual infeasibility
primal	use primal step size
primal-and-full	use the primal step size, and full step if $\delta_x \leq \alpha_{\text{for\_y\_tol}}$
safer-min-dual-infeas	like 'min-dual-infeas', but safeguarded by 'min' and 'max'

alpha_for_y_tol (*real*): Tolerance for switching to full equality multiplier steps. [↔](#)

This is only relevant if "alpha_for_y" is chosen "primal-and-full" or "dual-and-full". The step size for the equality constraint multipliers is taken to be one if the max-norm of the primal step is less than this tolerance.

Default: 10

alpha_min_frac (*real*): Safety factor for the minimal step size (before switching to restoration phase). [↔](#)

(This is gamma_alpha in Eqn. (20) in the implementation paper.)

Range: [0, 1]

Default: 0.05

alpha_red_factor (*real*): Fractional reduction of the trial step size in the backtracking line search. [↔](#)

At every step of the backtracking line search, the trial step size is reduced by this factor.

Range: [0, 1]

Default: 0.5

barrier_tol_factor (*real*): Factor for mu in barrier stop test. [↔](#)

The convergence tolerance for each barrier problem in the monotone mode is the value of the barrier parameter times "barrier_tol_factor". This option is also used in the adaptive mu strategy during the monotone mode. (This is kappa_epsilon in implementation paper).

Default: 10

bb_log_interval (*integer*): Interval at which node level output is printed. [↔](#)

Set the interval (in terms of number of nodes) at which a log on node resolutions (consisting of lower and upper bounds) is given.

Default: 100

bb_log_level (*integer*): specify main branch-and-bound log level. [↔](#)

Set the level of output of the branch-and-bound : 0 - none, 1 - minimal, 2 - normal low, 3 - normal high

Range: [0, 5]

Default: 1

bound_frac (*real*): Desired minimum relative distance from the initial point to bound. [↔](#)

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_push"). (This is kappa_2 in Section 3.6 of implementation paper.)

Range: [0, 0.5]

Default: 0.01

bound_mult_init_method (*string*): Initialization method for bound multipliers [↔](#)

This option defines how the iterates for the bound multipliers are initialized. If "constant" is chosen, then all bound multipliers are initialized to the value of "bound_mult_init_val". If "mu-based" is chosen, the each value is initialized to the the value of "mu_init" divided by the corresponding slack variable. This latter option might be useful if the starting point is close to the optimal solution.

Default: `constant`

value	meaning
constant	set all bound multipliers to the value of bound_mult_init_val
mu-based	initialize to mu_init/x_slack

bound_mult_init_val (*real*): Initial value for the bound multipliers. [↔](#)

All dual variables corresponding to bound constraints are initialized to this value.

Default: 1

bound_mult_reset_threshold (*real*): Threshold for resetting bound multipliers after the restoration phase. [↔](#)

After returning from the restoration phase, the bound multipliers are updated with a Newton step for complementarity. Here, the change in the primal variables during the entire restoration phase is taken to be the corresponding primal Newton step. However, if after the update the largest bound multiplier exceeds the threshold specified by this option, the multipliers are all reset to 1.

Default: 1000

bound_push (*real*): Desired minimum absolute distance from the initial point to bound. [↔](#)

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)

Default: 0.01

bound_relax_factor (*real*): Factor for initial relaxation of the bounds. [↔](#)

Before start of the optimization, the bounds given by the user are relaxed. This option sets the factor for this relaxation. If it is set to zero, then then bounds relaxation is disabled. (See Eqn.(35) in implementation paper.)

Default: 1e-10

candidate_sort_criterion (*string*): Choice of the criterion to choose candidates in strong-branching [↔](#)

Default: best-ps-cost

value	meaning
best-ps-cost	Sort by decreasing pseudo-cost
least-fractional	Sort by increasing integer infeasibility
most-fractional	Sort by decreasing integer infeasibility
worst-ps-cost	Sort by increasing pseudo-cost

check_derivatives_for_naninf (*string*): Indicates whether it is desired to check for Nan/Inf in derivative matrices [↔](#)

Activating this option will cause an error if an invalid number is detected in the constraint Jacobians or the Lagrangian Hessian. If this is not activated, the test is skipped, and the algorithm might proceed with invalid numbers and fail. If test is activated and an

invalid number is detected, the matrix is written to output with `print_level` corresponding to `J_MORE_DETAILED`; so beware of large output!

Default: `no`

value	meaning
<code>no</code>	Don't check (faster).
<code>yes</code>	Check Jacobians and Hessian for Nan and Inf.

clique_cuts (*integer*): Frequency (in terms of nodes) for generating clique cuts in branch-and-cut [↔](#)

See option `2mir_cuts` for a detailed description.

Range: $[-100, \infty]$

Default: `-5`

clocktype (*string*): Type of clock to use for `time_limit` [↔](#)

Default: `wall`

value	meaning
<code>cpu</code>	CPU time
<code>wall</code>	Wall-clock time

coeff_var_threshold (*real*): Coefficient of variation threshold (for dynamic definition of `cutoff_decr`). [↔](#)

Default: `0.1`

compl_inf_tol (*real*): Desired threshold for the complementarity conditions. [↔](#)

Absolute tolerance on the complementarity. Successful termination requires that the max-norm of the (unscaled) complementarity is less than this threshold.

Default: `0.0001`

constraint_violation_norm_type (*string*): Norm to be used for the constraint violation in the line search. [↔](#)

Determines which norm should be used when the algorithm computes the constraint violation in the line search.

Default: `1-norm`

value	meaning
<code>1-norm</code>	use the 1-norm
<code>2-norm</code>	use the 2-norm
<code>max-norm</code>	use the infinity norm

constr_mult_init_max (*real*): Maximum allowed least-square guess of constraint multipliers. [↔](#)

Determines how large the initial least-square guesses of the constraint multipliers are allowed to be (in max-norm). If the guess is larger than this value, it is discarded and all constraint

multipliers are set to zero. This options is also used when initializing the restoration phase. By default, "resto.constr_mult_init_max" (the one used in RestoIterateInitializer) is set to zero.

Default: 1000

constr_mult_reset_threshold (*real*): Threshold for resetting equality and inequality multipliers after restoration phase. [↔](#)

After returning from the restoration phase, the constraint multipliers are recomputed by a least square estimate. This option triggers when those least-square estimates should be ignored.

Default: 0

constr_viol_tol (*real*): Desired threshold for the constraint violation. [↔](#)

Absolute tolerance on the constraint violation. Successful termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold.

Default: 0.0001

corrector_compl_avrg_red_fact (*real*): Complementarity tolerance factor for accepting corrector step. [↔](#)

This option determines the factor by which complementarity is allowed to increase for a corrector step to be accepted. Changing this option is experimental.

Default: 1

corrector_type (*string*): The type of corrector steps that should be taken. [↔](#)

If "mu_strategy" is "adaptive", this option determines what kind of corrector steps should be tried. Changing this option is experimental.

Default: none

value	meaning
affine	corrector step towards mu=0
none	no corrector
primal-dual	corrector step towards current mu

cover_cuts (*integer*): Frequency (in terms of nodes) for generating cover cuts in branch-and-cut [↔](#)

See option 2mir.cuts for a detailed description.

Range: [-100, ∞]

Default: 0

cpx_parallel_strategy (*integer*): Strategy of parallel search mode in CPLEX. [↔](#)

-1 = opportunistic, 0 = automatic, 1 = deterministic (refer to CPLEX documentation)

Range: [-1, 1]

Default: 0

cutoff (*real*): Specify cutoff value. [↔](#)

cutoff should be the value of a feasible solution known by the user (if any). The algorithm will only look for solutions better than cutoff.

Range: $[-1\text{e}+100, 1\text{e}+100]$

Default: $1\text{e}+100$

cutoff_decr (*real*): Specify cutoff decrement. [↔](#)

Specify the amount by which cutoff is decremented below a new best upper-bound (usually a small positive value but in non-convex problems it may be a negative value).

Range: $[-1\text{e}+10, 1\text{e}+10]$

Default: $1\text{e}-05$

delta (*real*): Multiplier for constraint violation in the switching rule. [↔](#)

(See Eqn. (19) in the implementation paper.)

Default: 1

dependency_detection_with_rhs (*string*): Indicates if the right hand sides of the constraints should be considered during dependency detection [↔](#)

Default: no

value	meaning
no	only look at gradients
yes	also consider right hand side

dependency_detector (*string*): Indicates which linear solver should be used to detect linearly dependent equality constraints. [↔](#)

The default and available choices depend on how Ipopt has been compiled. This is experimental and does not work well.

Default: none

value	meaning
ma28	use MA28
mumps	use MUMPS
none	don't check; no extra work at beginning

diverging_iterates_tol (*real*): Threshold for maximal value of primal iterates. [↔](#)

If any component of the primal iterates exceeded this value (in absolute terms), the optimization is aborted with the exit message that the iterates seem to be diverging.

Default: $1\text{e}+20$

dual_inf_tol (*real*): Desired threshold for the dual infeasibility. [↔](#)

Absolute tolerance on the dual infeasibility. Successful termination requires that the max-norm of the (unscaled) dual infeasibility is less than this threshold.

Default: 1

dynamic_def_cutoff_decr (*string*): Do you want to define the parameter cutoff_decr dynamically? [↔](#)

Default: no

Values: no, yes

ecp_abs_tol (*real*): Set the absolute termination tolerance for ECP rounds. [↔](#)

Default: 1e-06

ecp_max_rounds (*integer*): Set the maximal number of rounds of ECP cuts. [↔](#)

Default: 5

ecp_probability_factor (*real*): Factor appearing in formula for skipping ECP cuts. [↔](#)

Choosing -1 disables the skipping.

Range: $[-\infty, \infty]$

Default: 10

ecp_rel_tol (*real*): Set the relative termination tolerance for ECP rounds. [↔](#)

Default: 0

enable_dynamic_nlp (*string*): Enable dynamic linear and quadratic rows addition in nlp [↔](#)

Default: no

Values: no, yes

eta_phi (*real*): Relaxation factor in the Armijo condition. [↔](#)

(See Eqn. (20) in the implementation paper)

Range: $[0, 0.5]$

Default: 1e-08

evaluate_orig_obj_at_resto_trial (*string*): Determines if the original objective function should be evaluated at restoration phase trial points. [↔](#)

Setting this option to "yes" makes the restoration phase algorithm evaluate the objective function of the original problem at every trial point encountered during the restoration phase, even if this value is not required. In this way, it is guaranteed that the original objective function can be evaluated without error at all accepted iterates; otherwise the algorithm might fail at a point where the restoration phase accepts an iterate that is good for the restoration phase problem, but not the original problem. On the other hand, if the evaluation of the original objective is expensive, this might be costly.

Default: yes

value	meaning
no	skip evaluation
yes	evaluate at every trial point

expect_infeasible_problem (*string*): Enable heuristics to quickly detect an infeasible problem. [↔](#)

This options is meant to activate heuristics that may speed up the infeasibility determination if you expect that there is a good chance for the problem to be infeasible. In the filter line search procedure, the restoration phase is called more quickly than usually, and more reduction in the constraint violation is enforced before the restoration phase is left. If the problem is square, this option is enabled automatically.

Default: **yes**

value	meaning
no	the problem probably be feasible
yes	the problem has a good chance to be infeasible

expect_infeasible_problem_ctol (*real*): Threshold for disabling 'expect_infeasible_problem' option. [↔](#)

If the constraint violation becomes smaller than this threshold, the "expect_infeasible_problem" heuristics in the filter line search are disabled. If the problem is square, this options is set to 0.

Default: 0.001

expect_infeasible_problem_ytol (*real*): Multiplier threshold for activating 'expect_infeasible_problem' option. [↔](#)

If the max norm of the constraint multipliers becomes larger than this value and "expect_infeasible_problem" is chosen, then the restoration phase is entered.

Default: 1e+08

fast_step_computation (*string*): Indicates if the linear system should be solved quickly. [↔](#)

If set to yes, the algorithm assumes that the linear system that is solved to obtain the search direction, is solved sufficiently well. In that case, no residuals are computed, and the computation of the search direction is a little faster.

Default: **no**

value	meaning
no	Verify solution of linear system by computing residuals.
yes	Trust that linear systems are solved well.

feasibility_pump_objective_norm (*integer*): Norm of feasibility pump objective function [↔](#)

Range: [1, 2]

Default: 1

feas_check_cut_types (*string*): Choose the type of cuts generated when an integer feasible solution is found [↔](#)

If it seems too much memory is used should try Benders to use less

Default: `outer-approx`

value	meaning
<code>benders</code>	Generate a single Benders cut.
<code>outer-approx</code>	Generate a set of Outer Approximations cuts.

feas_check_discard_policy (*string*): How cuts from feasibility checker are discarded [↔](#)

Normally to avoid cycle cuts from feasibility checker should not be discarded in the node where they are generated. However Cbc sometimes does it if no care is taken which can lead to an infinite loop in Bonmin (usually on simple problems). To avoid this one can instruct Cbc to never discard a cut but if we do that for all cuts it can lead to memory problems. The default policy here is to detect cycles and only then impose to Cbc to keep the cut. The two other alternative are to instruct Cbc to keep all cuts or to just ignore the problem and hope for the best

Default: `detect-cycles`

value	meaning
<code>detect-cycles</code>	Detect if a cycle occurs and only in this case force not to discard.
<code>keep-all</code>	Force cuts from feasibility checker not to be discarded (memory hungry but sometimes better).
<code>treated-as-normal</code>	Cuts from memory checker can be discarded as any other cuts (code may cycle then)

filmint_ecp_cuts (*integer*): Specify the frequency (in terms of nodes) at which some a la filmint ecp cuts are generated. [↔](#)

A frequency of 0 amounts to to never solve the NLP relaxation.

Default: 0

filter_margin_fact (*real*): Factor determining width of margin for obj-constr-filter adaptive globalization strategy. [↔](#)

When using the adaptive globalization strategy, "obj-constr-filter", sufficient progress for a filter entry is defined as follows: $(\text{new obj}) < (\text{filter obj}) - \text{filter\_margin\_fact} * (\text{new constr-viol})$ OR $(\text{new constr-viol}) < (\text{filter constr-viol}) - \text{filter\_margin\_fact} * (\text{new constr-viol})$. For the description of the "kkt-error-filter" option see "filter_max_margin".

Range: $[0, 1]$

Default: `1e-05`

filter_max_margin (*real*): Maximum width of margin in obj-constr-filter adaptive globalization strategy. [↔](#)

Default: 1

filter_reset_trigger (*integer*): Number of iterations that trigger the filter reset. [↔](#)

If the filter reset heuristic is active and the number of successive iterations in which the last rejected trial step size was rejected because of the filter, the filter is reset.

Range: $[1, \infty]$

Default: 5

first_hessian_perturbation (*real*): Size of first x-s perturbation tried. [↔](#)

The first value tried for the x-s perturbation in the inertia correction scheme. (This is `delta_0` in the implementation paper.)

Default: 0.0001

first_perc_for_cutoff_decr (*real*): The percentage used when, the coeff of variance is smaller than the threshold, to compute the `cutoff_decr` dynamically. [↔](#)

Range: $[-\infty, \infty]$

Default: -0.02

fixed_mu_oracle (*string*): Oracle for the barrier parameter when switching to fixed mode. [↔](#)

Determines how the first value of the barrier parameter should be computed when switching to the "monotone mode" in the adaptive strategy. (Only considered if "adaptive" is selected for option "mu_strategy".)

Default: `average_compl`

value	meaning
<code>average_compl</code>	base on current average complementarity
<code>loqo</code>	LOQO's centrality rule
<code>probing</code>	Mehrotra's probing heuristic
<code>quality-function</code>	minimize a quality function

fixed_variable_treatment (*string*): Determines how fixed variables should be handled. [↔](#)

The main difference between those options is that the starting point in the "make_constraint" case still has the fixed variables at their given values, whereas in the case "make_parameter" the functions are always evaluated with the fixed values for those variables. Also, for "relax_bounds", the fixing bound constraints are relaxed (according to "bound_relax_factor"). For both "make_constraints" and "relax_bounds", bound multipliers are computed for the fixed variables.

Default: `make_parameter`

value	meaning
<code>make_constraint</code>	Add equality constraints fixing variables
<code>make_parameter</code>	Remove fixed variable from optimization variables
<code>relax_bounds</code>	Relax fixing bound constraints

flow_cover_cuts (*integer*): Frequency (in terms of nodes) for generating flow cover cuts in branch-and-cut [↔](#)

See option `2mir_cuts` for a detailed description.

Range: $[-100, \infty]$

Default: -5

fp_log_frequency (*real*): display an update on lower and upper bounds in FP every n seconds ↩

Default: 100

fp_log_level (*integer*): specify FP iterations log level. ↩

Set the level of output of OA decomposition solver : 0 - none, 1 - normal, 2 - verbose

Range: $[0, 2]$

Default: 1

fp_pass_infeasible (*string*): Say whether feasibility pump should claim to converge or not ↩

Default: no

value	meaning
no	When master MILP is infeasible just bail out (don't stop all algorithm). This is the option for using in B-Hyb.
yes	Claim convergence, numerically dangerous.

gamma_phi (*real*): Relaxation factor in the filter margin for the barrier function. ↩

(See Eqn. (18a) in the implementation paper.)

Range: $[0, 1]$

Default: **1e-08**

gamma_theta (*real*): Relaxation factor in the filter margin for the constraint violation. ↩

(See Eqn. (18b) in the implementation paper.)

Range: $[0, 1]$

Default: 0.0001

generate_benders_after_so_many_oa (*integer*): Specify that after so many oa cuts have been generated Benders cuts should be generated instead. ↩

It seems that sometimes generating too many oa cuts slows down the optimization compared to Benders due to the size of the LP. With this option we specify that after so many OA cuts have been generated we should switch to Benders cuts.

Default: 5000

Gomory_cuts (*integer*): Frequency (in terms of nodes) for generating Gomory cuts in branch-and-cut. ↩

See option **2mir_cuts** for a detailed description.

Range: $[-100, \infty]$

Default: -5

hessian_approximation (*string*): Indicates what Hessian information is to be used. ↩

This determines which kind of information for the Hessian of the Lagrangian function is used by the algorithm.

Default: **exact**

value	meaning
exact	Use second derivatives provided by the NLP.
limited-memory	Perform a limited-memory quasi-Newton approximation

hessian_approximation_space (*string*): Indicates in which subspace the Hessian information is to be approximated. [↩](#)

Default: **nonlinear-variables**

value	meaning
all-variables	in space of all variables (without slacks)
nonlinear-variables	only in space of nonlinear variables.

heuristic_dive_fractional (*string*): if yes runs the Dive Fractional heuristic [↩](#)

Default: **no**

Values: **no**, **yes**

heuristic_dive_MIP_fractional (*string*): if yes runs the Dive MIP Fractional heuristic [↩](#)

Default: **no**

Values: **no**, **yes**

heuristic_dive_MIP_vectorLength (*string*): if yes runs the Dive MIP VectorLength heuristic [↩](#)

Default: **no**

Values: **no**, **yes**

heuristic_dive_vectorLength (*string*): if yes runs the Dive VectorLength heuristic [↩](#)

Default: **no**

Values: **no**, **yes**

heuristic_feasibility_pump (*string*): whether the heuristic feasibility pump should be used [↩](#)

Default: **no**

Values: **no**, **yes**

heuristic_RINS (*string*): if yes runs the RINS heuristic [↩](#)

Default: **no**

Values: **no**, **yes**

honor_original_bounds (*string*): Indicates whether final points should be projected into original bounds. [↩](#)

Ipopt might relax the bounds during the optimization (see, e.g., option "bound_relax_factor"). This option determines whether the final point should be projected back into the user-provide original bounds after the optimization.

Default: **yes**

value	meaning
no	Leave final point unchanged
yes	Project final point back into original bounds

inf_pr_output (*string*): Determines what value is printed in the 'inf_pr' output column. [↔](#)

Ipopt works with a reformulation of the original problem, where slacks are introduced and the problem might have been scaled. The choice "internal" prints out the constraint violation of this formulation. With "original" the true constraint violation in the original NLP is printed.

Default: `original`

value	meaning
internal	max-norm of violation of internal equality constraints
original	maximal constraint violation in original NLP

integer_tolerance (*real*): Set integer tolerance. [↔](#)

Any number within that value of an integer is considered integer.

Default: `1e-06`

iteration_limit (*integer*): Set the cumulative maximum number of iteration in the algorithm used to process nodes continuous relaxations in the branch-and-bound. [↔](#)

value 0 deactivates option.

Default: `maxint`

jacobian_regularization_exponent (*real*): Exponent for mu in the regularization for rank-deficient constraint Jacobians. [↔](#)

(This is kappa_c in the implementation paper.)

Default: `0.25`

jacobian_regularization_value (*real*): Size of the regularization for rank-deficient constraint Jacobians. [↔](#)

(This is bar delta_c in the implementation paper.)

Default: `1e-08`

jac_c_constant (*string*): Indicates whether all equality constraints are linear [↔](#)

Activating this option will cause Ipopt to ask for the Jacobian of the equality constraints only once from the NLP and reuse this information later.

Default: `no`

value	meaning
no	Don't assume that all equality constraints are linear
yes	Assume that equality constraints Jacobian are constant

jac_d_constant (*string*): Indicates whether all inequality constraints are linear [↔](#)

Activating this option will cause Ipopt to ask for the Jacobian of the inequality constraints only once from the NLP and reuse this information later.

Default: no

value	meaning
no	Don't assume that all inequality constraints are linear
yes	Assume that equality constraints Jacobian are constant

kappa_d (*real*): Weight for linear damping term (to handle one-sided bounds). [↔](#)

(see Section 3.7 in implementation paper.)

Default: 1e-05

kappa_sigma (*real*): Factor limiting the deviation of dual variables from primal estimates. [↔](#)

If the dual variables deviate from their primal estimates, a correction is performed. (See Eqn. (16) in the implementation paper.) Setting the value to less than 1 disables the correction.

Default: 1e+10

kappa_soc (*real*): Factor in the sufficient reduction rule for second order correction. [↔](#)

This option determines how much a second order correction step must reduce the constraint violation so that further correction steps are attempted. (See Step A-5.9 of Algorithm A in the implementation paper.)

Default: 0.99

least_square_init_duals (*string*): Least square initialization of all dual variables [↔](#)

If set to yes, Ipopt tries to compute least-square multipliers (considering ALL dual variables). If successful, the bound multipliers are possibly corrected to be at least bound_mult_init_val. This might be useful if the user doesn't know anything about the starting point, or for solving an LP or QP. This overwrites option "bound_mult_init_method".

Default: no

value	meaning
no	use bound_mult_init_val and least-square equality constraint multipliers
yes	overwrite user-provided point with least-square estimates

least_square_init_primal (*string*): Least square initialization of the primal variables [↔](#)

If set to yes, Ipopt ignores the user provided point and solves a least square problem for the primal variables (x and s), to fit the linearized equality and inequality constraints. This might be useful if the user doesn't know anything about the starting point, or for solving an LP or QP.

Default: no

value	meaning
no	take user-provided point
yes	overwrite user-provided point with least-square estimates

lift_and_project_cuts (*integer*): Frequency (in terms of nodes) for generating lift-and-project cuts in branch-and-cut [↩](#)

See option `2mir_cuts` for a detailed description.

Range: $[-100, \infty]$

Default: 0

limited_memory_aug_solver (*string*): Strategy for solving the augmented system for low-rank Hessian. [↩](#)

Default: `sherman-morrison`

value	meaning
extended	use an extended augmented system
sherman-morrison	use Sherman-Morrison formula

limited_memory_initialization (*string*): Initialization strategy for the limited memory quasi-Newton approximation. [↩](#)

Determines how the diagonal Matrix B_0 as the first term in the limited memory approximation should be computed.

Default: `scalar1`

value	meaning
constant	$\sigma = \text{limited\_memory\_init\_val}$
scalar1	$\sigma = s^T y / s^T s$
scalar2	$\sigma = y^T y / s^T y$
scalar3	arithmetic average of scalar1 and scalar2
scalar4	geometric average of scalar1 and scalar2

limited_memory_init_val (*real*): Value for B_0 in low-rank update. [↩](#)

The starting matrix in the low rank update, B_0 , is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Default: 1

limited_memory_init_val_max (*real*): Upper bound on value for B_0 in low-rank update. [↩](#)

The starting matrix in the low rank update, B_0 , is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Default: `1e+08`

limited_memory_init_val_min (*real*): Lower bound on value for B0 in low-rank update. [↔](#)

The starting matrix in the low rank update, B0, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Default: 1e-08

limited_memory_max_history (*integer*): Maximum size of the history for the limited quasi-Newton Hessian approximation. [↔](#)

This option determines the number of most recent iterations that are taken into account for the limited-memory quasi-Newton approximation.

Default: 6

limited_memory_max_skipping (*integer*): Threshold for successive iterations where update is skipped. [↔](#)

If the update is skipped more than this number of successive iterations, we quasi-Newton approximation is reset.

Range: $[1, \infty]$

Default: 2

limited_memory_special_for_resto (*string*): Determines if the quasi-Newton updates should be special during the restoration phase. [↔](#)

Until Nov 2010, Ipopt used a special update during the restoration phase, but it turned out that this does not work well. The new default uses the regular update procedure and it improves results. If for some reason you want to get back to the original update, set this option to "yes".

Default: no

value	meaning
no	use the same update as in regular iterations
yes	use the a special update during restoration phase

limited_memory_update_type (*string*): Quasi-Newton update formula for the limited memory approximation. [↔](#)

Determines which update formula is to be used for the limited-memory quasi-Newton approximation.

Default: bfgs

value	meaning
bfgs	BFGS update (with skipping)
sr1	SR1 (not working well)

linear_scaling_on_demand (*string*): Flag indicating that linear scaling is only done if it seems required. [↔](#)

This option is only important if a linear scaling method (e.g., mc19) is used. If you choose "no", then the scaling factors are computed for every linear system from the start. This can be quite expensive. Choosing "yes" means that the algorithm will start the scaling method only when the solutions to the linear system seem not good, and then use it until the end.

Default: **yes**

value	meaning
no	Always scale the linear system.
yes	Start using linear system scaling if solutions seem not good.

linear_solver (*string*): Linear solver used for step computations. [↔](#)

Determines which linear algebra package is to be used for the solution of the augmented linear system (for obtaining the search directions). Note, the code must have been compiled with the linear solver you want to choose. Depending on your Ipopt installation, not all options are available.

Default: **ma27**

value	meaning
ma27	use the Harwell routine MA27
ma57	use the Harwell routine MA57
ma77	use the Harwell routine HSL_MA77
ma86	use the Harwell routine HSL_MA86
ma97	use the Harwell routine HSL_MA97
mumps	use MUMPS package
pardiso	use the Pardiso package

linear_system_scaling (*string*): Method for scaling the linear system. [↔](#)

Determines the method used to compute symmetric scaling factors for the augmented system (see also the "linear_scaling_on_demand" option). This scaling is independent of the NLP problem scaling. By default, MC19 is only used if MA27 or MA57 are selected as linear solvers. This value is only available if Ipopt has been compiled with MC19.

Default: **mc19**

value	meaning
mc19	use the Harwell routine MC19
none	no scaling will be performed
slack-based	use the slack values

line_search_method (*string*): Globalization method used in backtracking line search [↔](#)

Only the "filter" choice is officially supported. But sometimes, good results might be obtained with the other choices.

Default: **filter**

value	meaning
cg-penalty	Chen-Goldfarb penalty function

value	meaning
filter	Filter method
penalty	Standard penalty function

lp_log_level (*integer*): specify LP log level. [↔](#)

Set the level of output of the linear programming sub-solver in B-Hyb or B-QG : 0 - none, 1 - minimal, 2 - normal low, 3 - normal high, 4 - verbose

Range: [0, 4]

Default: 0

ma27_ignore_singularity (*string*): Enables MA27's ability to solve a linear system even if the matrix is singular. [↔](#)

Setting this option to "yes" means that Ipopt will call MA27 to compute solutions for right hand sides, even if MA27 has detected that the matrix is singular (but is still able to solve the linear system). In some cases this might be better than using Ipopt's heuristic of small perturbation of the lower diagonal of the KKT matrix.

Default: no

value	meaning
no	Don't have MA27 solve singular systems
yes	Have MA27 solve singular systems

ma27_la_init_factor (*real*): Real workspace memory for MA27. [↔](#)

The initial real workspace memory = la_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by meminc_factor if required. This option is only available if Ipopt has been compiled with MA27.

Range: [1, ∞]

Default: 5

ma27_liw_init_factor (*real*): Integer workspace memory for MA27. [↔](#)

The initial integer workspace memory = liw_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by meminc_factor if required. This option is only available if Ipopt has been compiled with MA27.

Range: [1, ∞]

Default: 5

ma27_meminc_factor (*real*): Increment factor for workspace size for MA27. [↔](#)

If the integer or real workspace is not large enough, Ipopt will increase its size by this factor. This option is only available if Ipopt has been compiled with MA27.

Range: [1, ∞]

Default: 2

ma27_pivtol (*real*): Pivot tolerance for the linear solver MA27. [↔](#)

A smaller number pivots for sparsity, a larger number pivots for stability. This option is only available if Ipopt has been compiled with MA27.

Range: [0, 1]

Default: 1e-08

ma27_pivtolmax (*real*): Maximum pivot tolerance for the linear solver MA27. [↔](#)

Ipopt may increase pivtol as high as pivtolmax to get a more accurate solution to the linear system. This option is only available if Ipopt has been compiled with MA27.

Range: [0, 1]

Default: 0.0001

ma27_skip_inertia_check (*string*): Always pretend inertia is correct. [↔](#)

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Default: no

value	meaning
no	check inertia
yes	skip inertia check

ma28_pivtol (*real*): Pivot tolerance for linear solver MA28. [↔](#)

This is used when MA28 tries to find the dependent constraints.

Range: [0, 1]

Default: 0.01

ma57_automatic_scaling (*string*): Controls MA57 automatic scaling [↔](#)

This option controls the internal scaling option of MA57. For higher reliability of the MA57 solver, you may want to set this option to yes. This is ICNTL(15) in MA57.

Default: no

value	meaning
no	Do not scale the linear system matrix
yes	Scale the linear system matrix

ma57_block_size (*integer*): Controls block size used by Level 3 BLAS in MA57BD [↔](#)

This is ICNTL(11) in MA57.

Range: [1, ∞]

Default: 16

ma57_node_amalgamation (*integer*): Node amalgamation parameter [↔](#)

This is ICNTL(12) in MA57.

Range: $[1, \infty]$

Default: 16

ma57_pivot_order (*integer*): Controls pivot order in MA57 [↔](#)

This is ICNTL(6) in MA57.

Range: $[0, 5]$

Default: 5

ma57_pivtol (*real*): Pivot tolerance for the linear solver MA57. [↔](#)

A smaller number pivots for sparsity, a larger number pivots for stability. This option is only available if Ipopt has been compiled with MA57.

Range: $[0, 1]$

Default: 1e-08

ma57_pivtolmax (*real*): Maximum pivot tolerance for the linear solver MA57. [↔](#)

Ipopt may increase pivtol as high as ma57_pivtolmax to get a more accurate solution to the linear system. This option is only available if Ipopt has been compiled with MA57.

Range: $[0, 1]$

Default: 0.0001

ma57_pre_alloc (*real*): Safety factor for work space memory allocation for the linear solver MA57. [↔](#)

If 1 is chosen, the suggested amount of work space is used. However, choosing a larger number might avoid reallocation if the suggest values do not suffice. This option is only available if Ipopt has been compiled with MA57.

Range: $[1, \infty]$

Default: 1.05

ma57_small_pivot_flag (*integer*): If set to 1, then when small entries defined by CNTL(2) are detected they are removed and the corresponding pivots placed at the end of the factorization. This can be particularly efficient if the matrix is highly rank deficient. [↔](#)

This is ICNTL(16) in MA57.

Range: $[0, 1]$

Default: 0

ma77_buffer_lpage (*integer*): Number of scalars per MA77 buffer page [↔](#)

Number of scalars per an in-core buffer in the out-of-core solver MA77. Must be at most `ma77_file_size`.

Range: $[1, \infty]$

Default: 4096

ma77_buffer_npage (*integer*): Number of pages that make up MA77 buffer [↔](#)

Number of pages of size `buffer_lpage` that exist in-core for the out-of-core solver MA77.

Range: $[1, \infty]$

Default: 1600

ma77_file_size (*integer*): Target size of each temporary file for MA77, scalars per type [↔](#)

MA77 uses many temporary files, this option controls the size of each one. It is measured in the number of entries (int or double), NOT bytes.

Range: $[1, \infty]$

Default: 2097152

ma77_maxstore (*integer*): Maximum storage size for MA77 in-core mode [↔](#)

If greater than zero, the maximum size of factors stored in core before out-of-core mode is invoked.

Default: 0

ma77_nemin (*integer*): Node Amalgamation parameter [↔](#)

Two nodes in elimination tree are merged if result has fewer than `ma77_nemin` variables.

Range: $[1, \infty]$

Default: 8

ma77_order (*string*): Controls type of ordering used by HSL_MA77 [↔](#)

This option controls ordering for the solver HSL_MA77.

Default: `metis`

value	meaning
<code>amd</code>	Use the HSL_MC68 approximate minimum degree algorithm
<code>metis</code>	Use the MeTiS nested dissection algorithm (if available)

ma77_print_level (*integer*): Debug printing level for the linear solver MA77 [↔](#)

Range: $[-\infty, \infty]$

Default: -1

ma77_small (*real*): Zero Pivot Threshold [↔](#)

Any pivot less than `ma77_small` is treated as zero.

Default: `1e-20`

ma77_static (*real*): Static Pivoting Threshold [↔](#)

See MA77 documentation. Either `ma77_static=0.0` or `ma77_static>ma77_small`.
`ma77_static=0.0` disables static pivoting.

Default: `0`

ma77_u (*real*): Pivoting Threshold [↔](#)

See MA77 documentation.

Range: `[0, 0.5]`

Default: `1e-08`

ma77_umax (*real*): Maximum Pivoting Threshold [↔](#)

Maximum value to which `u` will be increased to improve quality.

Range: `[0, 0.5]`

Default: `0.0001`

ma86_nemin (*integer*): Node Amalgamation parameter [↔](#)

Two nodes in elimination tree are merged if result has fewer than `ma86_nemin` variables.

Range: `[1, ∞]`

Default: `32`

ma86_order (*string*): Controls type of ordering used by HSL_MA86 [↔](#)

This option controls ordering for the solver HSL_MA86.

Default: `auto`

value	meaning
<code>amd</code>	Use the HSL_MC68 approximate minimum degree algorithm
<code>auto</code>	Try both AMD and MeTiS, pick best
<code>metis</code>	Use the MeTiS nested dissection algorithm (if available)

ma86_print_level (*integer*): Debug printing level for the linear solver MA86 [↔](#)

Range: `[-∞, ∞]`

Default: `-1`

ma86_scaling (*string*): Controls scaling of matrix [↔](#)

This option controls scaling for the solver HSL_MA86.

Default: `mc64`

value	meaning
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]
none	Do not scale the linear system matrix

ma86_small (*real*): Zero Pivot Threshold [↔](#)

Any pivot less than `ma86_small` is treated as zero.

Default: `1e-20`

ma86_static (*real*): Static Pivoting Threshold [↔](#)

See MA86 documentation. Either `ma86_static=0.0` or `ma86_static>ma86_small`. `ma86_static=0.0` disables static pivoting.

Default: `0`

ma86_u (*real*): Pivoting Threshold [↔](#)

See MA86 documentation.

Range: `[0, 0.5]`

Default: `1e-08`

ma86_umax (*real*): Maximum Pivoting Threshold [↔](#)

Maximum value to which `u` will be increased to improve quality.

Range: `[0, 0.5]`

Default: `0.0001`

ma97_nemin (*integer*): Node Amalgamation parameter [↔](#)

Two nodes in elimination tree are merged if result has fewer than `ma97_nemin` variables.

Range: `[1, ∞]`

Default: `8`

ma97_order (*string*): Controls type of ordering used by HSL_MA97 [↔](#)

Default: `auto`

value	meaning
amd	Use the HSL_MC68 approximate minimum degree algorithm
auto	Use HSL_MA97 heuristic to guess best of AMD and METIS
best	Try both AMD and MeTiS, pick best
matched-amd	Use the HSL_MC80 matching based ordering with AMD
matched-auto	Use the HSL_MC80 matching with heuristic choice of AMD or METIS
matched-metis	Use the HSL_MC80 matching based ordering with METIS
metis	Use the MeTiS nested dissection algorithm

ma97_print_level (*integer*): Debug printing level for the linear solver MA97 [↔](#)

Range: $[-\infty, \infty]$

Default: 0

ma97_scaling (*string*): Specifies strategy for scaling in HSL_MA97 linear solver [↔](#)

Default: `dynamic`

value	meaning
<code>dynamic</code>	Dynamically select scaling according to rules specified by <code>ma97_scalingX</code> and <code>ma97_switchX</code> options.
<code>mc30</code>	Scale all linear system matrices using MC30
<code>mc64</code>	Scale all linear system matrices using MC64
<code>mc77</code>	Scale all linear system matrices using MC77 [1,3,0]
<code>none</code>	Do not scale the linear system matrix

ma97_scaling1 (*string*): First scaling. [↔](#)

If `ma97_scaling=dynamic`, this scaling is used according to the trigger `ma97_switch1`. If `ma97_switch2` is triggered it is disabled.

Default: `mc64`

value	meaning
<code>mc30</code>	Scale linear system matrix using MC30
<code>mc64</code>	Scale linear system matrix using MC64
<code>mc77</code>	Scale linear system matrix using MC77 [1,3,0]
<code>none</code>	No scaling

ma97_scaling2 (*string*): Second scaling. [↔](#)

If `ma97_scaling=dynamic`, this scaling is used according to the trigger `ma97_switch2`. If `ma97_switch3` is triggered it is disabled.

Default: `mc64`

value	meaning
<code>mc30</code>	Scale linear system matrix using MC30
<code>mc64</code>	Scale linear system matrix using MC64
<code>mc77</code>	Scale linear system matrix using MC77 [1,3,0]
<code>none</code>	No scaling

ma97_scaling3 (*string*): Third scaling. [↔](#)

If `ma97_scaling=dynamic`, this scaling is used according to the trigger `ma97_switch3`.

Default: `mc64`

value	meaning
mc30	Scale linear system matrix using MC30
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]
none	No scaling

ma97_small (*real*): Zero Pivot Threshold ↩

Any pivot less than ma97_small is treated as zero.

Default: 1e-20

ma97_solve_blas3 (*string*): Controls if blas2 or blas3 routines are used for solve ↩

Default: no

value	meaning
no	Use BLAS2 (faster, some implementations bit incompatible)
yes	Use BLAS3 (slower)

ma97_switch1 (*string*): First switch, determine when ma97_scaling1 is enabled. ↩

If ma97_scaling=dynamic, ma97_scaling1 is enabled according to this condition. If ma97_switch2 occurs this option is henceforth ignored.

Default: od_hd_reuse

value	meaning
at_start	Scaling to be used from the very start.
at_start_reuse	Scaling to be used on first iteration, then reused thereafter.
high_delay	Scaling to be used after more than 0.05*n delays are present
high_delay_reuse	Scaling to be used only when previous itr created more than 0.05*n additional delays, otherwise reuse scaling from previous itr
never	Scaling is never enabled.
od_hd	Combination of on_demand and high_delay
od_hd_reuse	Combination of on_demand_reuse and high_delay_reuse
on_demand	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
on_demand_reuse	As on_demand, but reuse scaling from previous itr

ma97_switch2 (*string*): Second switch, determine when ma97_scaling2 is enabled. ↩

If ma97_scaling=dynamic, ma97_scaling2 is enabled according to this condition. If ma97_switch3 occurs this option is henceforth ignored.

Default: never

value	meaning
at_start	Scaling to be used from the very start.
at_start_reuse	Scaling to be used on first iteration, then reused thereafter.

value	meaning
high_delay	Scaling to be used after more than 0.05*n delays are present
high_delay_reuse	Scaling to be used only when previous itr created more than 0.05*n additional delays, otherwise reuse scaling from previous itr
never	Scaling is never enabled.
od_hd	Combination of on_demand and high_delay
od_hd_reuse	Combination of on_demand_reuse and high_delay_reuse
on_demand	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
on_demand_reuse	As on_demand, but reuse scaling from previous itr

ma97_switch3 (*string*): Third switch, determine when ma97_scaling3 is enabled. ↩

If ma97_scaling=dynamic, ma97_scaling3 is enabled according to this condition.

Default: **never**

value	meaning
at_start	Scaling to be used from the very start.
at_start_reuse	Scaling to be used on first iteration, then reused thereafter.
high_delay	Scaling to be used after more than 0.05*n delays are present
high_delay_reuse	Scaling to be used only when previous itr created more than 0.05*n additional delays, otherwise reuse scaling from previous itr
never	Scaling is never enabled.
od_hd	Combination of on_demand and high_delay
od_hd_reuse	Combination of on_demand_reuse and high_delay_reuse
on_demand	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
on_demand_reuse	As on_demand, but reuse scaling from previous itr

ma97_u (*real*): Pivoting Threshold ↩

See MA97 documentation.

Range: [0, 0.5]

Default: 1e-08

ma97_umax (*real*): Maximum Pivoting Threshold ↩

See MA97 documentation.

Range: [0, 0.5]

Default: 0.0001

maxmin_crit_have_sol (*real*): Weight towards minimum in of lower and upper branching estimates when a solution has been found. ↩

Range: [0, 1]

Default: 0.1

maxmin_crit_no_sol (*real*): Weight towards minimum in of lower and upper branching estimates when no solution has been found yet. [↔](#)

Range: [0, 1]

Default: 0.7

max_consecutive_failures (*integer*): (temporarily removed) Number n of consecutive unsolved problems before aborting a branch of the tree. [↔](#)

When $n > 0$, continue exploring a branch of the tree until n consecutive problems in the branch are unsolved (we call unsolved a problem for which Ipopt can not guarantee optimality within the specified tolerances).

Default: 10

max_consecutive_infeasible (*integer*): Number of consecutive infeasible subproblems before aborting a branch. [↔](#)

Will continue exploring a branch of the tree until "max_consecutive_infeasible" consecutive problems are locally infeasible by the NLP sub-solver.

Default: 0

max_cpu_time (*real*): Maximum number of CPU seconds. [↔](#)

A limit on CPU seconds that Ipopt can use to solve one problem. If during the convergence check this limit is exceeded, Ipopt will terminate with a corresponding error message.

Default: 1e+06

max_filter_resets (*integer*): Maximal allowed number of filter resets [↔](#)

A positive number enables a heuristic that resets the filter, whenever in more than "filter_reset_trigger" successive iterations the last rejected trial steps size was rejected because of the filter. This option determine the maximal number of resets that are allowed to take place.

Default: 5

max_hessian_perturbation (*real*): Maximum value of regularization parameter for handling negative curvature. [↔](#)

In order to guarantee that the search directions are indeed proper descent directions, Ipopt requires that the inertia of the (augmented) linear system for the step computation has the correct number of negative and positive eigenvalues. The idea is that this guides the algorithm away from maximizers and makes Ipopt more likely converge to first order optimal points that are minimizers. If the inertia is not correct, a multiple of the identity matrix is added to the Hessian of the Lagrangian in the augmented system. This parameter gives the maximum value of the regularization parameter. If a regularization of that size is not enough, the algorithm skips this iteration and goes to the restoration phase. (This is $\delta_w^{\max}$ in the implementation paper.)

Default: 1e+20

max_iter (*integer*): Maximum number of iterations. [↔](#)

The algorithm terminates with an error message if the number of iterations exceeded this number.

Default: 3000

max_random_point_radius (*real*): Set max value r for coordinate of a random point. [↔](#)

When picking a random point, coordinate i will be in the interval $[\min(\max(l, -r), u - r), \max(\min(u, r), l + r)]$ (where l is the lower bound for the variable and u is its upper bound)

Default: 100000

max_refinement_steps (*integer*): Maximum number of iterative refinement steps per linear system solve. [↔](#)

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the maximum number of iterative refinement steps.

Default: 10

max_resto_iter (*integer*): Maximum number of successive iterations in restoration phase. [↔](#)

The algorithm terminates with an error message if the number of iterations successively taken in the restoration phase exceeds this number.

Default: 3000000

max_soc (*integer*): Maximum number of second order correction trial steps at each iteration. [↔](#)

Choosing 0 disables the second order corrections. (This is $p^{\{\max\}}$ of Step A-5.9 of Algorithm A in the implementation paper.)

Default: 4

max_soft_resto_iters (*integer*): Maximum number of iterations performed successively in soft restoration phase. [↔](#)

If the soft restoration phase is performed for more than so many iterations in a row, the regular restoration phase is called.

Default: 10

mehrotra_algorithm (*string*): Indicates if we want to do Mehrotra's algorithm. [↔](#)

If set to yes, Ipopt runs as Mehrotra's predictor-corrector algorithm. This works usually very well for LPs and convex QPs. This automatically disables the line search, and chooses the (unglobalized) adaptive μ strategy with the "probing" oracle, and uses "corrector_type=affine" without any safeguards; you should not set any of those options explicitly in addition. Also, unless otherwise specified, the values of "bound_push", "bound_frac", and "bound_mult_init_val" are set more aggressive, and sets "alpha_for_y=bound_mult".

Default: no

value	meaning
no	Do the usual Ipopt algorithm.
yes	Do Mehrotra's predictor-corrector algorithm.

milp_log_level (*integer*): specify MILP solver log level. [↔](#)

Set the level of output of the MILP subsolver in OA : 0 - none, 1 - minimal, 2

- normal low, 3 - normal high

Range: [0, 4]

Default: 0

milp_solver (*string*): Choose the subsolver to solve MILP sub-problems in OA decompositions. ↩

To use Cplex, a valid license is required.

Default: Cbc_D

value	meaning
cbc_d	Coin Branch and Cut with its default
cbc_par	Coin Branch and Cut with passed parameters
cplex	IBM Cplex

milp_strategy (*string*): Choose a strategy for MILPs. ↩

Default: solve_to_optimality

value	meaning
find_good_sol	Stop sub milps when a solution improving the incumbent is found
solve_to_optimality	Solve MILPs to optimality

min_hessian_perturbation (*real*): Smallest perturbation of the Hessian block. ↩

The size of the perturbation of the Hessian block is never selected smaller than this value, unless no perturbation is necessary. (This is $\delta_{\min}$ in implementation paper.)

Default: 1e-20

min_number_strong_branch (*integer*): Sets minimum number of variables for strong branching (overriding trust) ↩

Default: 0

min_refinement_steps (*integer*): Minimum number of iterative refinement steps per linear system solve. ↩

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the minimum number of iterative refinements (i.e. at least "min_refinement_steps" iterative refinement steps are enforced per right hand side.)

Default: 1

mir_cuts (*integer*): Frequency (in terms of nodes) for generating MIR cuts in branch-and-cut ↩

See option 2mir_cuts for a detailed description.

Range: [-100, ∞]

Default: -5

mumps_dep_tol (*real*): Pivot threshold for detection of linearly dependent constraints in MUMPS. [↔](#)

When MUMPS is used to determine linearly dependent constraints, this determines the threshold for a pivot to be considered zero. This is CNTL(3) in MUMPS.

Range: $[-\infty, \infty]$

Default: 0

mumps_mem_percent (*integer*): Percentage increase in the estimated working space for MUMPS. [↔](#)

In MUMPS when significant extra fill-in is caused by numerical pivoting, larger values of `mumps_mem_percent` may help use the workspace more efficiently. On the other hand, if memory requirements are too large at the very beginning of the optimization, choosing a much smaller value for this option, such as 5, might reduce memory requirements.

Default: 1000

mumps_permuting_scaling (*integer*): Controls permuting and scaling in MUMPS [↔](#)

This is ICNTL(6) in MUMPS.

Range: $[0, 7]$

Default: 7

mumps_pivot_order (*integer*): Controls pivot order in MUMPS [↔](#)

This is ICNTL(7) in MUMPS.

Range: $[0, 7]$

Default: 7

mumps_pivtol (*real*): Pivot tolerance for the linear solver MUMPS. [↔](#)

A smaller number pivots for sparsity, a larger number pivots for stability. This option is only available if Ipopt has been compiled with MUMPS.

Range: $[0, 1]$

Default: $1e-06$

mumps_pivtolmax (*real*): Maximum pivot tolerance for the linear solver MUMPS. [↔](#)

Ipopt may increase `pivtol` as high as `pivtolmax` to get a more accurate solution to the linear system. This option is only available if Ipopt has been compiled with MUMPS.

Range: $[0, 1]$

Default: 0.1

mumps_scaling (*integer*): Controls scaling in MUMPS [↔](#)

This is ICNTL(8) in MUMPS.

Range: $[-2, 77]$

Default: 77

mu_allow_fast_monotone_decrease (*string*): Allow skipping of barrier problem if barrier test is already met. [↔](#)

If set to "no", the algorithm enforces at least one iteration per barrier problem, even if the barrier test is already met for the updated barrier parameter.

Default: yes

value	meaning
no	Take at least one iteration per barrier problem
yes	Allow fast decrease of mu if barrier test it met

mu_init (*real*): Initial value for the barrier parameter. [↔](#)

This option determines the initial value for the barrier parameter (μ). It is only relevant in the monotone, Fiacco-McCormick version of the algorithm. (i.e., if "mu_strategy" is chosen as "monotone")

Default: 0.1

mu_linear_decrease_factor (*real*): Determines linear decrease rate of barrier parameter. [↔](#)

For the Fiacco-McCormick update procedure the new barrier parameter μ is obtained by taking the minimum of $\mu \cdot \text{mu\_linear\_decrease\_factor}$ and $\mu^{\text{superlinear\_decrease\_power}}$. (This is κ_μ in implementation paper.) This option is also used in the adaptive μ strategy during the monotone mode.

Range: [0, 1]

Default: 0.2

mu_max (*real*): Maximum value for barrier parameter. [↔](#)

This option specifies an upper bound on the barrier parameter in the adaptive μ selection mode. If this option is set, it overwrites the effect of mu_max_fact. (Only used if option "mu_strategy" is chosen as "adaptive".)

Default: 100000

mu_max_fact (*real*): Factor for initialization of maximum value for barrier parameter. [↔](#)

This option determines the upper bound on the barrier parameter. This upper bound is computed as the average complementarity at the initial point times the value of this option. (Only used if option "mu_strategy" is chosen as "adaptive".)

Default: 1000

mu_min (*real*): Minimum value for barrier parameter. [↔](#)

This option specifies the lower bound on the barrier parameter in the adaptive μ selection mode. By default, it is set to the minimum of $1e-11$ and $\min(\text{"tol"}, \text{"compl\_inf\_tol"})/(\text{"barrier\_tol\_factor"} + 1)$, which should be a reasonable value. (Only used if option "mu_strategy" is chosen as "adaptive".)

Default: $1e-11$

mu_oracle (*string*): Oracle for a new barrier parameter in the adaptive strategy. [↔](#)

Determines how a new barrier parameter is computed in each "free-mode" iteration of the adaptive barrier parameter strategy. (Only considered if "adaptive" is selected for option "mu_strategy").

Default: probing

value	meaning
loqo	LOQO's centrality rule
probing	Mehrotra's probing heuristic
quality-function	minimize a quality function

mu_strategy (*string*): Update strategy for barrier parameter. [↔](#)

Determines which barrier parameter update strategy is to be used.

Default: **adaptive**

value	meaning
adaptive	use the adaptive update strategy
monotone	use the monotone (Fiacco-McCormick) strategy

mu_superlinear_decrease_power (*real*): Determines superlinear decrease rate of barrier parameter. [↔](#)

For the Fiacco-McCormick update procedure the new barrier parameter μ is obtained by taking the minimum of $\mu * \text{mu\_linear\_decrease\_factor}$ and $\mu^{\text{mu\_superlinear\_decrease\_power}}$. (This is θ_{μ} in implementation paper.) This option is also used in the adaptive μ strategy during the monotone mode.

Range: [1, 2]

Default: 1.5

mu_target (*real*): Desired value of complementarity. [↔](#)

Usually, the barrier parameter is driven to zero and the termination test for complementarity is measured with respect to zero complementarity. However, in some cases it might be desired to have Ipopt solve barrier problem for strictly positive value of the barrier parameter. In this case, the value of "mu_target" specifies the final value of the barrier parameter, and the termination tests are then defined with respect to the barrier problem for this value of the barrier parameter.

Default: 0

neg_curv_test_reg (*string*): Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014). [↔](#)

Default: **yes**

value	meaning
no	use original IPOPT approach, in which the primal regularization is ignored
yes	use primal regularization with the inertia-free curvature test

neg_curv_test_tol (*real*): Tolerance for heuristic to ignore wrong inertia. [↔](#)

If nonzero, incorrect inertia in the augmented system is ignored, and Ipopt tests if the direction is a direction of positive curvature. This tolerance is α_n in the paper by Zavala and Chiang (2014) and it determines when the direction is considered to be sufficiently positive. A value in the range of [1e-12, 1e-11] is recommended.

Default: 0

nlp_failure_behavior (*string*): Set the behavior when an NLP or a series of NLP are unsolved by Ipopt (we call unsolved an NLP for which Ipopt is not able to guarantee optimality within the specified tolerances). [↔](#)

If set to "fathom", the algorithm will fathom the node when Ipopt fails to find a solution to the nlp at that node within the specified tolerances. The algorithm then becomes a heuristic, and the user will be warned that the solution might not be optimal.

Default: **stop**

value	meaning
fathom	Continue when failure happens.
stop	Stop when failure happens.

nlp_log_at_root (*integer*): specify a different log level for root relaxation. [↔](#)

Range: [0, 12]

Default: 5

nlp_log_level (*integer*): specify NLP solver interface log level (independent from ipopt print_level). [↔](#)

Set the level of output of the OsiTMINLPInterface : 0 - none, 1 - normal, 2 - verbose

Range: [0, 2]

Default: 1

nlp_scaling_constr_target_gradient (*real*): Target value for constraint function gradient size. [↔](#)

If a positive number is chosen, the scaling factor the constraint functions is computed so that the gradient has the max norm of the given size at the starting point. This overrides nlp_scaling_max_gradient for the constraint functions.

Default: 0

nlp_scaling_max_gradient (*real*): Maximum gradient after NLP scaling. [↔](#)

This is the gradient scaling cut-off. If the maximum gradient is above this value, then gradient based scaling will be performed. Scaling parameters are calculated to scale the maximum gradient back to this value. (This is g_max in Section 3.8 of the implementation paper.) Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Default: 100

nlp_scaling_method (*string*): Select the technique used for scaling the NLP. [↔](#)

Selects the technique used for scaling the problem internally before it is solved. For user-scaling, the parameters come from the NLP. If you are using AMPL, they can be specified through suffixes ("scaling_factor")

Default: **gradient-based**

value	meaning
equilibration-based	scale the problem so that first derivatives are of order 1 at random points (only available with MC19)
gradient-based	scale the problem so the maximum gradient at the starting point is scaling_max_gradient
none	no problem scaling will be performed

nlp_scaling_min_value (*real*): Minimum value of gradient-based scaling values. [↔](#)

This is the lower bound for the scaling factors computed by gradient-based scaling method. If some derivatives of some functions are huge, the scaling factors will otherwise become very small, and the (unscaled) final constraint violation, for example, might then be significant. Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Default: 1e-08

nlp_scaling_obj_target_gradient (*real*): Target value for objective function gradient size. [↔](#)

If a positive number is chosen, the scaling factor the objective function is computed so that the gradient has the max norm of the given size at the starting point. This overrides nlp_scaling_max_gradient for the objective function.

Default: 0

nlp_solves_per_depth (*real*): Set average number of nodes in the tree at which NLP relaxations are solved in B-Hyb for each depth. [↔](#)

Default: 1e+100

nlp_solve_frequency (*integer*): Specify the frequency (in terms of nodes) at which NLP relaxations are solved in B-Hyb. [↔](#)

A frequency of 0 amounts to to never solve the NLP relaxation.

Default: 10

nlp_solve_max_depth (*integer*): Set maximum depth in the tree at which NLP relaxations are solved in B-Hyb. [↔](#)

A depth of 0 amounts to to never solve the NLP relaxation.

Default: 10

node_comparison (*string*): Choose the node selection strategy. [↔](#)

Choose the strategy for selecting the next node to be processed.

Default: best-bound

value	meaning
best-bound	choose node with the smallest bound,
best-guess	choose node with smallest guessed integer solution
breadth-first	Perform breadth first search,
depth-first	Perform depth first search,
dynamic	Cbc dynamic strategy (starts with a depth first search and turn to best bound after 3 integer feasible solutions have been found).

node_limit (*integer*): Set the maximum number of nodes explored in the branch-and-bound search. [↔](#)

Default: `maxint`

number_before_trust (*integer*): Set the number of branches on a variable before its pseudo costs are to be believed in dynamic strong branching. [↔](#)

A value of 0 disables pseudo costs.

Default: 8

number_before_trust_list (*integer*): Set the number of branches on a variable before its pseudo costs are to be believed during setup of strong branching candidate list. [↔](#)

The default value is that of "number_before_trust"

Range: $[-1, \infty]$

Default: 0

number_cpx_threads (*integer*): Set number of threads to use with cplex. [↔](#)

(refer to CPLEX documentation)

Default: 1

number_look_ahead (*integer*): Sets limit of look-ahead strong-branching trials [↔](#)

Default: 0

number_strong_branch (*integer*): Choose the maximum number of variables considered for strong branching. [↔](#)

Set the number of variables on which to do strong branching.

Default: 20

number_strong_branch_root (*integer*): Maximum number of variables considered for strong branching in root node. [↔](#)

Default: `maxint`

num_cut_passes (*integer*): Set the maximum number of cut passes at regular nodes of the branch-and-cut. [↔](#)

Default: 1

num_cut_passes_at_root (*integer*): Set the maximum number of cut passes at regular nodes of the branch-and-cut. [↔](#)

Default: 20

num_iterations_suspect (*integer*): Number of iterations over which a node is considered 'suspect' (for debugging purposes only, see detailed documentation). [↔](#)

When the number of iterations to solve a node is above this number, the subproblem at this node is considered to be suspect and it will be written into a file (set to -1 to deactivate this).

Range: $[-1, \infty]$

Default: -1

num_resolve_at_infeasibles (*integer*): Number k of tries to resolve an infeasible node (other than the root) of the tree with different starting point. ↩

The algorithm will solve all the infeasible nodes with k different random starting points and will keep the best local optimum found.

Default: 0

num_resolve_at_node (*integer*): Number k of tries to resolve a node (other than the root) of the tree with different starting point. ↩

The algorithm will solve all the nodes with k different random starting points and will keep the best local optimum found.

Default: 0

num_resolve_at_root (*integer*): Number k of tries to resolve the root node with different starting points. ↩

The algorithm will solve the root node with k random starting points and will keep the best local optimum found.

Default: 0

num_retry_unsolved_random_point (*integer*): Number k of times that the algorithm will try to resolve an unsolved NLP with a random starting point (we call unsolved an NLP for which Ipopt is not able to guarantee optimality within the specified tolerances). ↩

When Ipopt fails to solve a continuous NLP sub-problem, if $k > 0$, the algorithm will try again to solve the failed NLP with k new randomly chosen starting points or until the problem is solved with success.

Default: 0

nu_inc (*real*): Increment of the penalty parameter. ↩

Default: 0.0001

nu_init (*real*): Initial value of the penalty parameter. ↩

Default: 1e-06

oa_cuts_log_level (*integer*): level of log when generating OA cuts. ↩

0: outputs nothing, 1: when a cut is generated, its violation and index of row from which it originates, 2: always output violation of the cut. 3: output generated cuts incidence vectors.

Default: 0

oa_cuts_scope (*string*): Specify if OA cuts added are to be set globally or locally valid ↩

Default: global

value	meaning
global	Cuts are treated as globally valid
local	Cuts are treated as locally valid

oa_decomposition (*string*): If yes do initial OA decomposition ↩

Default: no

Values: no, yes

oa_log_frequency (*real*): display an update on lower and upper bounds in OA every n seconds ↩

Default: 100

oa_log_level (*integer*): specify OA iterations log level. ↩

Set the level of output of OA decomposition solver : 0 - none, 1 - normal, 2 - verbose

Range: [0, 2]

Default: 1

oa_rhs_relax (*real*): Value by which to relax OA cut ↩

RHS of OA constraints will be relaxed by this amount times the absolute value of the initial rhs if it is ≥ 1 (otherwise by this amount).

Default: 1e-08

obj_max_inc (*real*): Determines the upper bound on the acceptable increase of barrier objective function. ↩

Trial points are rejected if they lead to an increase in the barrier objective function by more than obj_max_inc orders of magnitude.

Range: [1, ∞]

Default: 5

pardiso_matching_strategy (*string*): Matching strategy to be used by Pardiso ↩

This is IPAR(13) in Pardiso manual.

Default: complete+2x2

value	meaning
complete	Match complete (IPAR(13)=1)
complete+2x2	Match complete+2x2 (IPAR(13)=2)
constraints	Match constraints (IPAR(13)=3)

pardiso_max_iterative_refinement_steps (*integer*): Limit on number of iterative refinement steps. ↩

The solver does not perform more than the absolute value of this value steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. If negative, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement. The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and this option is set to 0.

Range: $[-\infty, \infty]$

Default: 1

pardiso_msglvl (*integer*): Pardiso message level [↔](#)

This determines the amount of analysis output from the Pardiso solver. This is MSGVLV in the Pardiso manual.

Default: 0

pardiso_order (*string*): Controls the fill-in reduction ordering algorithm for the input matrix. [↔](#)

Default: **metis**

value	meaning
amd	minimum degree algorithm
metis	MeTiS nested dissection algorithm
one	undocumented
pmetis	parallel (OpenMP) version of MeTiS nested dissection algorithm

pardiso_redo_symbolic_fact_only_if_inertia_wrong (*string*): Toggle for handling case when elements were perturbed by Pardiso. [↔](#)

Default: **no**

value	meaning
no	Always redo symbolic factorization when elements were perturbed
yes	Only redo symbolic factorization when elements were perturbed if also the inertia was wrong

pardiso_repeated_perturbation_means_singular (*string*): Interpretation of perturbed elements. [↔](#)

Default: **no**

value	meaning
no	Don't assume that matrix is singular if elements were perturbed after recent symbolic factorization
yes	Assume that matrix is singular if elements were perturbed after recent symbolic factorization

pardiso_skip_inertia_check (*string*): Always pretend inertia is correct. [↔](#)

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Default: **no**

value	meaning
no	check inertia
yes	skip inertia check

perturb_always_cd (*string*): Active permanent perturbation of constraint linearization. [↩](#)

This options makes the delta_c and delta_d perturbation be used for the computation of every search direction. Usually, it is only used when the iteration matrix is singular.

Default: **no**

value	meaning
no	perturbation only used when required
yes	always use perturbation

perturb_dec_fact (*real*): Decrease factor for x-s perturbation. [↩](#)

The factor by which the perturbation is decreased when a trial value is deduced from the size of the most recent successful perturbation. (This is κ_w^- in the implementation paper.)

Range: $[0, 1]$

Default: 0.333333

perturb_inc_fact (*real*): Increase factor for x-s perturbation. [↩](#)

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of all perturbations except for the first. (This is κ_w^+ in the implementation paper.)

Range: $[1, \infty]$

Default: 8

perturb_inc_fact_first (*real*): Increase factor for x-s perturbation for very first perturbation. [↩](#)

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of the very first perturbation and allows a different value for for the first perturbation than that used for the remaining perturbations. (This is $\bar{\kappa}_w^+$ in the implementation paper.)

Range: $[1, \infty]$

Default: 100

print_eval_error (*string*): Switch to enable printing information about function evaluation errors into the GAMS listing file. [↩](#)

Default: **yes**

Values: **no**, **yes**

print_frequency_iter (*integer*): Determines at which iteration frequency the summarizing iteration output line should be printed. [↩](#)

Summarizing iteration output is printed every print_frequency_iter iterations, if at least print_frequency_time seconds have passed since last output.

Range: $[1, \infty]$

Default: 1

print_frequency_time (*real*): Determines at which time frequency the summarizing iteration output line should be printed. ↩

Summarizing iteration output is printed if at least `print_frequency_time` seconds have passed since last output and the iteration number is a multiple of `print_frequency_iter`.

Default: 0.5

print_funceval_statistics (*string*): Switch to enable printing statistics on number of evaluations of GAMS functions/gradients/Hessian. ↩

Default: no

Values: no, yes

print_info_string (*string*): Enables printing of additional info string at end of iteration output. ↩

This string contains some insider information about the current iteration. For details, look for "Diagnostic Tags" in the Ipopt documentation.

Default: no

value	meaning
no	don't print string
yes	print string at end of each iteration output

print_level (*integer*): Output verbosity level. ↩

Sets the default verbosity level for console output. The larger this value the more detailed is the output.

Range: [0, 12]

Default: 0

print_timing_statistics (*string*): Switch to print timing statistics. ↩

If selected, the program will print the CPU usage (user time) for selected tasks.

Default: no

value	meaning
no	don't print statistics
yes	print all timing statistics

pump_for_minlp (*string*): whether to run the feasibility pump heuristic for MINLP ↩

Default: no

Values: no, yes

quality_function_balancing_term (*string*): The balancing term included in the quality function for centrality. ↩

This determines whether a term is added to the quality function that penalizes situations where the complementarity is much smaller than dual and primal infeasibilities. (Only used if option "mu_oracle" is set to "quality-function".)

Default: none

value	meaning
cubic	$\text{Max}(0, \text{Max}(\text{dual\_inf}, \text{primal\_inf}) - \text{compl})^3$
none	no balancing term is added

quality_function_centrality (*string*): The penalty term for centrality that is included in quality function. [↔](#)

This determines whether a term is added to the quality function to penalize deviation from centrality with respect to complementarity. The complementarity measure here is the xi in the Logo update rule. (Only used if option "mu_oracle" is set to "quality-function".)

Default: none

value	meaning
cubed-reciprocal	complementarity * the reciprocal of the centrality measure cubed
log	complementarity * the log of the centrality measure
none	no penalty term is added
reciprocal	complementarity * the reciprocal of the centrality measure

quality_function_max_section_steps (*integer*): Maximum number of search steps during direct search procedure determining the optimal centering parameter. [↔](#)

The golden section search is performed for the quality function based mu oracle. (Only used if option "mu_oracle" is set to "quality-function".)

Default: 8

quality_function_norm_type (*string*): Norm used for components of the quality function. [↔](#)

(Only used if option "mu_oracle" is set to "quality-function".)

Default: 2-norm-squared

value	meaning
1-norm	use the 1-norm (abs sum)
2-norm	use 2-norm
2-norm-squared	use the 2-norm squared (sum of squares)
max-norm	use the infinity norm (max)

quality_function_section_qf_tol (*real*): Tolerance for the golden section search procedure determining the optimal centering parameter (in the function value space). [↔](#)

The golden section search is performed for the quality function based mu oracle. (Only used if option "mu_oracle" is set to "quality-function".)

Range: [0, 1]

Default: 0

quality_function_section_sigma_tol (*real*): Tolerance for the section search procedure determining the optimal centering parameter (in sigma space). [↩](#)

The golden section search is performed for the quality function based mu oracle. (Only used if option "mu_oracle" is set to "quality-function".)

Range: [0, 1]

Default: 0.01

random_generator_seed (*integer*): Set seed for random number generator (a value of -1 sets seeds to time since Epoch). [↩](#)

Range: [-1, ∞]

Default: 0

random_point_perturbation_interval (*real*): Amount by which starting point is perturbed when choosing to pick random point by perturbing starting point [↩](#)

Default: 1

random_point_type (*string*): method to choose a random starting point [↩](#)

Default: Jon

value	meaning
andreas	perturb the starting point of the problem within a prescribed interval
claudia	perturb the starting point using the perturbation radius suffix information
jon	Choose random point uniformly between the bounds

read_solution_file (*string*): Read a file with the optimal solution to test if algorithms cuts it. [↩](#)

For Debugging purposes only.

Default: no

Values: no, yes

recalc_y (*string*): Tells the algorithm to recalculate the equality and inequality multipliers as least square estimates. [↩](#)

This asks the algorithm to recompute the multipliers, whenever the current infeasibility is less than `recalc_y_feas_tol`. Choosing yes might be helpful in the quasi-Newton option. However, each recalculation requires an extra factorization of the linear system. If a limited memory quasi-Newton option is chosen, this is used by default.

Default: no

value	meaning
no	use the Newton step to update the multipliers
yes	use least-square multiplier estimates

recalc_y_feas_tol (*real*): Feasibility threshold for recomputation of multipliers. ↩

If `recalc_y` is chosen and the current infeasibility is less than this value, then the multipliers are recomputed.

Default: `1e-06`

reduce_and_split_cuts (*integer*): Frequency (in terms of nodes) for generating reduce-and-split cuts in branch-and-cut ↩

See option `2mir_cuts` for a detailed description.

Range: $[-100, \infty]$

Default: `0`

replace_bounds (*string*): Indicates if all variable bounds should be replaced by inequality constraints ↩

This option must be set for the inexact algorithm

Default: `no`

value	meaning
<code>no</code>	leave bounds on variables
<code>yes</code>	replace variable bounds by inequality constraints

required_infeasibility_reduction (*real*): Required reduction of infeasibility before leaving restoration phase. ↩

The restoration phase algorithm is performed, until a point is found that is acceptable to the filter and the infeasibility has been reduced by at least the fraction given by this option.

Range: $[0, 1]$

Default: `0.1`

residual_improvement_factor (*real*): Minimal required reduction of residual test ratio in iterative refinement. ↩

If the improvement of the residual test ratio made by one iterative refinement step is not better than this factor, iterative refinement is aborted.

Default: `1`

residual_ratio_max (*real*): Iterative refinement tolerance ↩

Iterative refinement is performed until the residual test ratio is less than this tolerance (or until "max_refinement_steps" refinement steps are performed).

Default: `1e-10`

residual_ratio_singular (*real*): Threshold for declaring linear system singular after failed iterative refinement. ↩

If the residual test ratio is larger than this value after failed iterative refinement, the algorithm pretends that the linear system is singular.

Default: `1e-05`

resolve_on_small_infeasibility (*real*): If a locally infeasible problem is infeasible by less than this, resolve it with initial starting point. [↵](#)

Default: 0

resto_failure_feasibility_threshold (*real*): Threshold for primal infeasibility to declare failure of restoration phase. [↵](#)

If the restoration phase is terminated because of the "acceptable" termination criteria and the primal infeasibility is smaller than this value, the restoration phase is declared to have failed. The default value is $1e2 * tol$, where tol is the general termination tolerance.

Default: 0

resto_penalty_parameter (*real*): Penalty parameter in the restoration phase objective function. [↵](#)

This is the parameter ρ in equation (31a) in the Ipopt implementation paper.

Default: 1000

resto_proximity_weight (*real*): Weighting factor for the proximity term in restoration phase objective. [↵](#)

This determines how the parameter ζ in equation (29a) in the implementation paper is computed. ζ here is $resto\_proximity\_weight * \sqrt{\mu}$, where μ is the current barrier parameter.

Default: 1

rho (*real*): Value in penalty parameter update formula. [↵](#)

Range: $[0, 1]$

Default: 0.1

second_perc_for_cutoff_decr (*real*): The percentage used when, the coeff of variance is greater than the threshold, to compute the cutoff_decr dynamically. [↵](#)

Range: $[-\infty, \infty]$

Default: -0.05

setup_pseudo_frac (*real*): Proportion of strong branching list that has to be taken from most-integer-infeasible list. [↵](#)

Range: $[0, 1]$

Default: 0.5

sigma_max (*real*): Maximum value of the centering parameter. [↵](#)

This is the upper bound for the centering parameter chosen by the quality function based barrier parameter update. (Only used if option "mu_oracle" is set to "quality-function".)

Default: 100

sigma_min (*real*): Minimum value of the centering parameter. [↵](#)

This is the lower bound for the centering parameter chosen by the quality function based barrier parameter update. (Only used if option "mu_oracle" is set to "quality-function".)

Default: $1e-06$

skip_corr_if_neg_curv (*string*): Skip the corrector step in negative curvature iteration. [↵](#)

The corrector step is not tried if negative curvature has been encountered during the computation of the search direction in the current iteration. This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Default: yes

value	meaning
no	don't skip
yes	skip

skip_corr_in_monotone_mode (*string*): Skip the corrector step during monotone barrier parameter mode. [↔](#)

The corrector step is not tried if the algorithm is currently in the monotone mode (see also option "barrier_strategy"). This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Default: yes

value	meaning
no	don't skip
yes	skip

slack_bound_frac (*real*): Desired minimum relative distance from the initial slack to bound. [↔](#)

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_push"). (This is kappa_2 in Section 3.6 of implementation paper.)

Range: [0, 0.5]

Default: 0.01

slack_bound_push (*real*): Desired minimum absolute distance from the initial slack to bound. [↔](#)

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)

Default: 0.01

slack_move (*real*): Correction size for very small slacks. [↔](#)

Due to numerical issues or the lack of an interior, the slack variables might become very small. If a slack becomes very small compared to machine precision, the corresponding bound is moved slightly. This parameter determines how large the move should be. Its default value is $\text{mach\_eps}^{3/4}$. (See also end of Section 3.5 in implementation paper - but actual implementation might be somewhat different.)

Default: 1.81899e-12

soc_method (*integer*): Ways to apply second order correction [↔](#)

This option determines the way to apply second order correction, 0 is the method described in the implementation paper. 1 is the modified way which adds alpha on the rhs of x and s rows.

Range: [0, 1]

Default: 0

soft_resto_pderror_reduction_factor (*real*): Required reduction in primal-dual error in the soft restoration phase. [↔](#)

The soft restoration phase attempts to reduce the primal-dual error with regular steps. If the damped primal-dual step (damped only to satisfy the fraction-to-the-boundary rule) is not decreasing the primal-dual error by at least this factor, then the regular restoration phase is called. Choosing "0" here disables the soft restoration phase.

Default: 0.9999

solution_limit (*integer*): Abort after that much integer feasible solution have been found by algorithm [↔](#)

value 0 deactivates option

Default: **maxint**

solvefinal (*string*): Switch to disable solving MINLP with discrete variables fixed to solution values after solve. [↔](#)

If enabled, then the dual values from the resolved NLP are made available in GAMS.

Default: **yes**

Values: **no**, **yes**

solvetrace (*string*): Name of file for writing solving progress information. [↔](#)

solvetracenodefreq (*integer*): Frequency in number of nodes for writing solving progress information. [↔](#)

giving 0 disables writing of N-lines to trace file

Default: 100

solvetracetimefreq (*real*): Frequency in seconds for writing solving progress information. [↔](#)

giving 0.0 disables writing of T-lines to trace file

Default: 5

start_with_resto (*string*): Tells algorithm to switch to restoration phase in first iteration. [↔](#)

Setting this option to "yes" forces the algorithm to switch to the feasibility restoration phase in the first iteration. If the initial point is feasible, the algorithm will abort with a failure.

Default: **no**

value	meaning
no	don't force start in restoration phase
yes	force start in restoration phase

s_max (*real*): Scaling threshold for the NLP error. [↔](#)

(See paragraph after Eqn. (6) in the implementation paper.)

Default: 100

s_phi (*real*): Exponent for linear barrier function model in the switching rule. [↩](#)

(See Eqn. (19) in the implementation paper.)

Range: $[1, \infty]$

Default: 2.3

s_theta (*real*): Exponent for current constraint violation in the switching rule. [↩](#)

(See Eqn. (19) in the implementation paper.)

Range: $[1, \infty]$

Default: 1.1

tau_min (*real*): Lower bound on fraction-to-the-boundary parameter tau. [↩](#)

(This is tau_min in the implementation paper.) This option is also used in the adaptive mu strategy during the monotone mode.

Range: $[0, 1]$

Default: 0.99

theta_max_fact (*real*): Determines upper bound for constraint violation in the filter. [↩](#)

The algorithmic parameter theta_max is determined as theta_max_fact times the maximum of 1 and the constraint violation at initial point. Any point with a constraint violation larger than theta_max is unacceptable to the filter (see Eqn. (21) in the implementation paper).

Default: 10000

theta_min_fact (*real*): Determines constraint violation threshold in the switching rule. [↩](#)

The algorithmic parameter theta_min is determined as theta_min_fact times the maximum of 1 and the constraint violation at initial point. The switching rules treats an iteration as an h-type iteration whenever the current constraint violation is larger than theta_min (see paragraph before Eqn. (19) in the implementation paper).

Default: 0.0001

time_limit (*real*): Set the global maximum computation time (in secs) for the algorithm. [↩](#)

Default: 1000

tiny_element (*real*): Value for tiny element in OA cut [↩](#)

We will remove "cleanly" (by relaxing cut) an element lower than this.

Default: 1e-08

tiny_step_tol (*real*): Tolerance for detecting numerically insignificant steps. [↩](#)

If the search direction in the primal variables (x and s) is, in relative terms for each component, less than this value, the algorithm accepts the full step without line search. If this happens repeatedly, the algorithm will terminate with a corresponding exit message. The default value is 10 times machine precision.

Default: 2.22045e-15

tiny_step_y_tol (*real*): Tolerance for quitting because of numerically insignificant steps. [↔](#)

If the search direction in the primal variables (x and s) is, in relative terms for each component, repeatedly less than tiny_step_tol, and the step in the y variables is smaller than this threshold, the algorithm will terminate.

Default: 0.01

tol (*real*): Desired convergence tolerance (relative). [↔](#)

Determines the convergence tolerance for the algorithm. The algorithm terminates successfully, if the (scaled) NLP error becomes smaller than this value, and if the (absolute) criteria according to "dual_inf_tol", "constr_viol_tol", and "compl_inf_tol" are met. (This is epsilon_tol in Eqn. (6) in implementation paper). See also "acceptable_tol" as a second termination criterion. Note, some other algorithmic features also use this quantity to determine thresholds etc.

Default: 1e-08

tree_search_strategy (*string*): Pick a strategy for traversing the tree [↔](#)

All strategies can be used in conjunction with any of the node comparison functions. Options which affect dfs-dive are max-backtracks-in-dive and max-dive-depth. The dfs-dive won't work in a non-convex problem where objective does not decrease down branches.

Default: probed-dive

value	meaning
dfs-dive	Dive in the tree if possible doing a depth first search. Backtrack on leaves or when a prescribed depth is attained or when estimate of best possible integer feasible solution in subtree is worst than cutoff.
dfs-dive-dynamic	Same as dfs-dive but once enough solution are found switch to best-bound and if too many nodes switch to depth-first.
dive	Dive in the tree if possible, otherwise pick top node as sorted by the tree comparison function.
probed-dive	Dive in the tree exploring two children before continuing the dive at each level.
top-node	Always pick the top node as sorted by the node comparison function

trust_strong_branching_for_pseudo_cost (*string*): Whether or not to trust strong branching results for updating pseudo costs. [↔](#)

Default: yes

Values: no, yes

variable_selection (*string*): Chooses variable selection strategy [↔](#)

Default: strong-branching

value	meaning
lp-strong-branching	Perform strong branching with LP approximation
most-fractional	Choose most fractional variable
nlp-strong-branching	Perform strong branching with NLP approximation
osi-simple	Osi method to do simple branching
osi-strong	Osi method to do strong branching
qp-strong-branching	Perform strong branching with QP approximation
random	Method to choose branching variable randomly
reliability-branching	Use reliability branching
strong-branching	Perform strong branching

very_tiny_element (*real*): Value for very tiny element in OA cut ↩

Algorithm will take the risk of neglecting an element lower than this.

Default: 1e-17

warm_start (*string*): Select the warm start method ↩

This will affect the function getWarmStart(), and as a consequence the warm starting in the various algorithms.

Default: none

value	meaning
fake_basis	builds fake basis, useful for cut management in Cbc (warm start is the same as in none)
interior_point	Warm start with an interior point of direct parent
none	No warm start, just start NLPs from optimal solution of the root relaxation
optimum	Warm start with direct parent optimum

warm_start_bound_frac (*real*): same as bound_frac for the regular initializer. ↩

Range: [0, 0.5]

Default: 0.001

warm_start_bound_push (*real*): same as bound_push for the regular initializer. ↩

Default: 0.001

warm_start_init_point (*string*): Warm-start for initial point ↩

Indicates whether this optimization should use a warm start initialization, where values of primal and dual variables are given (e.g., from a previous optimization of a related problem.)

Default: yes

value	meaning
no	do not use the warm start initialization
yes	use the warm start initialization

warm_start_mult_bound_push (*real*): same as mult_bound_push for the regular initializer. [↔](#)

Default: 0.001

warm_start_mult_init_max (*real*): Maximum initial value for the equality multipliers. [↔](#)

Range: $[-\infty, \infty]$

Default: 1e+06

warm_start_slack_bound_frac (*real*): same as slack_bound_frac for the regular initializer. [↔](#)

Range: $[0, 0.5]$

Default: 0.001

warm_start_slack_bound_push (*real*): same as slack_bound_push for the regular initializer. [↔](#)

Default: 0.001

watchdog_shortened_iter_trigger (*integer*): Number of shortened iterations that trigger the watchdog. [↔](#)

If the number of successive iterations in which the backtracking line search did not accept the first trial point exceeds this number, the watchdog procedure is activated. Choosing "0" here disables the watchdog procedure.

Default: 10

watchdog_trial_iter_max (*integer*): Maximum number of watchdog iterations. [↔](#)

This option determines the number of trial iterations allowed before the watchdog procedure is aborted and the algorithm returns to the stored point.

Range: $[1, \infty]$

Default: 3

5.10 CBC

CBC (COIN-OR Branch and Cut) is an open-source mixed integer programming solver working with the COIN-OR LP solver **CLP** and the COIN-OR Cut generator library **Cg1**. The code has been written primarily by John J. Forrest. Most of the CBC documentation in the section was copied from the help in the CBC standalone version.

The CBC link in GAMS supports continuous, binary, integer, semicontinuous, semiinteger variables, special ordered sets of type 1 and 2, and branching priorities.

5.10.1 Usage

The following statement can be used inside your GAMS program to specify using CBC

```
Option LP = CBC;      { or MIP or RMIP }
```

The above statement should appear before the Solve statement. If CBC was specified as the default solver during GAMS installation, the above statement is not necessary.

For usage and syntax of solver options file, see Section [The Solver Option File](#). Following is an example options file `cbc.opt`.

```
cuts root
perturbation off
```

It will cause CBC to use cut generators only in the root node and turns off the perturbation of the LP relaxation.

GAMS/CBC currently does not support the GAMS Branch-and-Cut-and-Heuristic (BCH) Facility. If you need to use GAMS/CBC with BCH, please consider to use a **GAMS system of version ≤ 23.3** .

The following GAMS parameters are currently supported by GAMS/CBC: [reslim](#), [iterlim](#), [nodlim](#), [optca](#), [optcr](#), [cheat](#), [cutoff](#), and [threads](#).

5.10.2 List of Options

There are many parameters which can affect the performance the CBCs Branch and Cut Algorithm. First just try with default settings and look carefully at the log file. Did cuts help? Did they take too long? Look at the output to see which cuts were effective and then do some tuning (see the option [cuts](#)). If the [preprocessing](#) reduced the size of the problem or strengthened many coefficients then it is probably wise to leave it on. Switch off [heuristics](#) which did not provide solutions. The other major area to look at is the search. Hopefully good solutions were obtained fairly early in the search so the important point is to select the best variable to branch on. See whether strong branching did a good job – or did it just take a lot of iterations? Adjust the options [strongBranching](#) and [trustpseudocosts](#).

In the following, we summarize all available CBC options.

5.10.2.1 General Options

Option	Description	Default
clocktype	type of clock for time measurement	wall
reslim	maximum seconds	GAMS reslim
special	options passed unseen to CBC	
writemps	create MPS file for problem	

5.10.2.2 LP Options

Option	Description	Default
autoScale	Whether to scale objective, rhs and bounds of problem if they look odd (experimental)	0
biasLU	Whether factorization biased towards U	LX
bscale	Whether to scale in barrier (and ordering speed)	off
crash	Whether to create basis for problem	off
crossover	Whether to get a basic solution with the simplex algorithm after the barrier algorithm finished	on
denseThreshold	Threshold for using dense factorization	-1
dualPivot	Dual pivot choice algorithm	automatic
factorization	Which factorization to use	normal
gamma	Whether to regularize barrier	off
idiotCrash	Whether to try idiot crash	-1
iterlim	Maximum number of iterations before stopping	GAMS iterlim
KKT	Whether to use KKT factorization in barrier	0
maxFactor	Maximum number of iterations between refactorizations	200
passPresolve	How many passes in presolve	5
perturbation	Whether to perturb the problem	1
presolve	Whether to presolve problem	on
primalPivot	Primal pivot choice algorithm	automatic
primalWeight	Initially algorithm acts as if it costs this much to be infeasible	1e+10
psi	Two-dimension pricing factor for Positive Edge criterion	-0.5
randomSeedClp	Random seed for Clp	1234567
scaling	Whether to scale problem	automatic
smallFactorization	Threshold for using small factorization	-1
sparseFactor	Whether factorization treated as sparse	1
sprintCrash	Whether to try sprint crash	-1
startalg	LP solver for root node	dual
substitution	How long a column to substitute for in presolve	3
tol_dual	For an optimal solution no dual infeasibility may exceed this value	1e-07
tol_presolve	Tolerance to use in presolve	1e-08
tol_primal	For a feasible solution no primal infeasibility, i.e., constraint violation, may exceed this value	1e-07

5.10.2.3 MIP Options

Option	Description	Default
costStrategy	How to use costs for branching priorities	off
cutoff	Bound on the objective value for all solutions	GAMS cutoff
cutoffConstraint	Whether to use cutoff as constraint	off
dumpsolutions	name of solutions index gdx file for writing alternate solutions	
dumpsolutionsmerged	name of gdx file for writing all alternate solutions	
expensiveStrong	Whether to do even more strong branching	0
extraVariables	Allow creation of extra integer variables	0
fixOnDj	Try heuristic based on fixing variables with reduced costs greater than this	-1
increment	A valid solution must be at least this much better than last integer solution	GAMS cheat
infeasibilityWeight	Each integer infeasibility is expected to cost this much	0
loglevel	amount of output printed by CBC	1
maxsol	Maximum number of solutions to save	100
mipstart	whether it should be tried to use the initial variable levels as initial MIP solution	0
multipleRootPasses	Do multiple root passes to collect cuts and solutions	0
nodeStrategy	What strategy to use to select the next node from the branch and cut tree	fewest
nodlim	node limit	GAMS nodlim
optca	Stop when gap between best possible and best less than this	GAMS optca
optcr	Stop when gap between best possible and best known is less than this fraction of larger of two	GAMS optcr
OrbitalBranching	Whether to try orbital branching	off
parallelmode	whether to run opportunistic or deterministic	deterministic
preprocess	Whether to use integer preprocessing	sos
printfrequency	frequency of status prints	0
randomSeedCbc	Random seed for Cbc	-1
sollim	Maximum number of feasible solutions to get	maxint
solvefinal	final solve of MIP with fixed discrete variables	1
solvetrace	name of trace file for solving information	
solvetracenodefreq	frequency in number of nodes for writing to solve trace file	100
solvetracetimefreq	frequency in seconds for writing to solve trace file	5
sosPrioritize	How to deal with SOS priorities	off
strategy	Switches on groups of features	1
strongBranching	Number of variables to look at in strong branching	5

Option	Description	Default
threads	Number of threads to try and use	GAMS threads
tol_integer	For a feasible solution no integer variable may be more than this away from an integer value	1e-07
trustPseudoCosts	Number of branches before we trust pseudocosts	10

5.10.2.4 MIP Options for Cutting Plane Generators

Option	Description	Default
cliqueCuts	Whether to use Clique cuts	ifmove
conflictcuts	Conflict Cuts	0
cutDepth	Depth in tree at which to do cuts	-1
cutLength	Length of a cut	-1
cuts	Switches all cut generators on or off	on
cut_passes_root	Number of rounds that cut generators are applied in the root node	20 or 100
cut_passes_slow	Maximum number of rounds for slower cut generators	10
cut_passes_tree	Number of rounds that cut generators are applied in the tree	10
flowCoverCuts	Whether to use Flow Cover cuts	ifmove
gomoryCuts	Whether to use Gomory cuts	ifmove
gomorycuts2	Whether to use alternative Gomory cuts	off
knapsackCuts	Whether to use Knapsack cuts	ifmove
lagomoryCuts	Whether to use Lagrangean Gomory cuts	off
latwomirCuts	Whether to use Lagrangean TwoMir cuts	off
liftAndProjectCuts	Whether to use Lift and Project cuts	off
mirCuts	Whether to use Mixed Integer Rounding cuts	ifmove
probingCuts	Whether to use Probing cuts	ifmove
reduceAndSplitCuts	Whether to use Reduce-and-Split cuts	off
reduceAndSplitCuts2	Whether to use Reduce-and-Split cuts - style 2	off
residualCapacityCuts	Whether to use Residual Capacity cuts	off
twoMirCuts	Whether to use Two phase Mixed Integer Rounding cuts	root
zeroHalfCuts	Whether to use zero half cuts	ifmove

5.10.2.5 MIP Options for Primal Heuristics

Option	Description	Default
combine2Solutions	Whether to use crossover solution heuristic	off

Option	Description	Default
<code>combineSolutions</code>	Whether to use combine solution heuristic	<code>off</code>
<code>Dins</code>	Whether to try Distance Induced Neighborhood Search	<code>off</code>
<code>diveSolves</code>	Diving solve option	100
<code>DivingCoefficient</code>	Whether to try Coefficient diving heuristic	<code>off</code>
<code>DivingFractional</code>	Whether to try Fractional diving heuristic	<code>off</code>
<code>DivingGuided</code>	Whether to try Guided diving heuristic	<code>off</code>
<code>DivingLineSearch</code>	Whether to try Linesearch diving heuristic	<code>off</code>
<code>DivingPseudoCost</code>	Whether to try Pseudocost diving heuristic	<code>off</code>
<code>DivingRandom</code>	Whether to try Diving heuristics	<code>off</code>
<code>DivingVectorLength</code>	Whether to try Vectorlength diving heuristic	<code>off</code>
<code>dwHeuristic</code>	Whether to try Dantzig Wolfe heuristic	<code>off</code>
<code>feaspump</code>	Whether to try the Feasibility Pump heuristic	<code>on</code>
<code>feaspump_artcost</code>	Costs $\geq$ this treated as artificials in feasibility pump	0
<code>feaspump_cutoff</code>	Fake cutoff for use in feasibility pump	0
<code>feaspump_fracbab</code>	Fraction in feasibility pump	0.5
<code>feaspump_increment</code>	Fake increment for use in feasibility pump	0
<code>feaspump_passes</code>	How many passes to do in the Feasibility Pump heuristic	20
<code>greedyHeuristic</code>	Whether to use a greedy heuristic	<code>on</code>
<code>heuristics</code>	Switches most primal heuristics on or off	1
<code>hOptions</code>	Heuristic options	0
<code>localTreeSearch</code>	Whether to use local tree search when a solution is found	0
<code>naiveHeuristics</code>	Whether to try some stupid heuristic	<code>off</code>
<code>pivotAndComplement</code>	Whether to try Pivot and Complement heuristic	<code>off</code>
<code>pivotAndFix</code>	Whether to try Pivot and Fix heuristic	<code>off</code>
<code>proximitySearch</code>	Whether to do proximity search heuristic	<code>off</code>
<code>randomizedRounding</code>	Whether to try randomized rounding heuristic	<code>off</code>
<code>Rens</code>	Whether to try Relaxation Enforced Neighborhood Search	<code>off</code>
<code>Rins</code>	Whether to try Relaxed Induced Neighborhood Search	<code>off</code>
<code>roundingHeuristic</code>	Whether to use simple (but effective) Rounding heuristic	<code>on</code>
<code>VndVariableNeighborhoodSearch</code>	Whether to try Variable Neighborhood Search	<code>off</code>
<code>vubheuristic</code>	Type of VUB heuristic	-1

5.10.3 Detailed Options Description

In the following, we give a detailed description of all available CBC options.

autoScale (*boolean*): Whether to scale objective, rhs and bounds of problem if they look odd (experimental) [↔](#)

Default: 0

biasLU (*string*): Whether factorization biased towards U [↔](#)

Default: LX

Values: ll, lx, uu, ux

bscale (*string*): Whether to scale in barrier (and ordering speed) [↔](#)

Default: off

Values: off, off1, off2, on, on1, on2

cliqueCuts (*string*): Whether to use Clique cuts [↔](#)

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: <https://github.com/coin-or/Cgl/wiki/CglClique>

Default: ifmove

Values: forceon, ifmove, off, on, onglobal, root

clocktype (*string*): type of clock for time measurement [↔](#)

Default: wall

value	meaning
cpu	CPU clock
wall	Wall clock

combine2Solutions (*string*): Whether to use crossover solution heuristic [↔](#)

This heuristic does branch and cut on the problem given by fixing variables which have the same value in two or more solutions. It obviously only tries after two or more solutions. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

Values: before, both, off, on

combineSolutions (*string*): Whether to use combine solution heuristic [↔](#)

This heuristic does branch and cut on given problem by just using variables which have appeared in one or more solutions. It is obviously only tried after two or more solutions have been found. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
beforequick	
both	
bothquick	
off	
on	
onquick	

conflictcuts (*boolean*): Conflict Cuts ↩

Equivalent to setting cutoffconstraint=conflict

Default: 0

costStrategy (*string*): How to use costs for branching priorities ↩

Value 'priorities' assigns highest priority to variables with largest absolute cost. This primitive strategy can be surprisingly effective. Value 'columnorder' assigns the priorities 1, 2, 3, ... with respect to the column ordering. Value '01first' ('01last') assigns two sets of priorities such that binary variables get high (low) priority. Value 'length' assigns high priority to variables that occur in many equations.

Default: off

value	meaning
01first	
01last	
binaryfirst	This is a deprecated setting. Please use 01first.
binarylast	This is a deprecated setting. Please use 01last.
columnorder	
generalforce	
length	
nonzero	
off	
priorities	
singletons	

crash (*string*): Whether to create basis for problem ↩

If crash is set to 'on' and there is an all slack basis then Clp will flip or put structural variables into the basis with the aim of getting dual feasible. On average, dual simplex seems to perform

better without it and there are alternative types of 'crash' for primal simplex, e.g. 'idiot' or 'sprint'. A variant due to Solow and Halim which is as 'on' but just flips is also available.

Default: `off`

Values: `idiot1`, `idiot2`, `idiot3`, `idiot4`, `idiot5`, `idiot6`, `idiot7`, `lots`, `off`, `on`, `solow_halim`

crossover (*string*): Whether to get a basic solution with the simplex algorithm after the barrier algorithm finished ↩

Interior point algorithms do not obtain a basic solution. This option will crossover to a basic solution suitable for ranging or branch and cut.

Default: `on`

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
off	
on	
presolve	

cutDepth (*integer*): Depth in tree at which to do cuts ↩

Cut generators may be off, on, on only at the root node, or on if they look useful. Setting this option to a positive value K let CBC call a cutgenerator on a node whenever the depth in the tree is a multiple of K. The default of -1 lets CBC decide.

Range: $[-1, \infty]$

Default: `-1`

cutLength (*integer*): Length of a cut ↩

At present this only applies to Gomory cuts. -1 (default) leaves as is. Any value >0 says that all cuts $\leq$ this length can be generated both at root node and in tree. 0 says to use some dynamic lengths. If value $\geq 10,000,000$ then the length in tree is value - so 10000100 means unlimited length at root and 100 in tree.

Range: $[-1, \infty]$

Default: `-1`

cutoff (*real*): Bound on the objective value for all solutions ↩

A valid solution must be at least this much better than last integer solution. If this option is not set then it CBC will try and work one out. E.g., if all objective coefficients are multiples of 0.01 and only integer variables have entries in objective then this can be set to 0.01.

Range: $[-\infty, \infty]$

Default: `GAMS cutoff`

cutoffConstraint (*string*): Whether to use cutoff as constraint ↩

Synonym: `constraintfromCutoff`

For some problems, cut generators and general branching work better if the problem would be infeasible if the cost is too high. If this option is enabled, the objective function is added as a constraint which right hand side is set to the current cutoff value (objective value of best known solution)

Default: `off`

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
conflict	
forcevariable	
off	
on	
variable	

cuts (*string*): Switches all cut generators on or off ↔

Synonym: cutsOnOff

This can be used to switch on or off all cut generators (apart from Reduce and Split). Then one can turn individual ones off or on. Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node.

Default: on

Values: forceon, ifmove, off, on, root

cut_passes_root (*integer*): Number of rounds that cut generators are applied in the root node ↔

Synonym: passCuts

The default is to do 100 passes if the problem has less than 500 columns, 100 passes (but stop if the drop in the objective function value is small) if the problem has less than 5000 columns, and 20 passes otherwise. A negative value -n means that n passes are also applied if the objective does not drop.

Range: $[-\infty, \infty]$

Default: 20 or 100

cut_passes_slow (*integer*): Maximum number of rounds for slower cut generators ↔

Synonym: slowcutpasses

Some cut generators are fairly slow - this limits the number of times they are tried. The cut generators identified as 'may be slow' at present are Lift and project cuts and both versions of Reduce and Split cuts.

Range: $[-1, \infty]$

Default: 10

cut_passes_tree (*integer*): Number of rounds that cut generators are applied in the tree ↔

Synonym: passTreeCuts

The default is to do one pass. A negative value -n means that n passes are also applied if the objective does not drop.

Range: $[-\infty, \infty]$

Default: 10

denseThreshold (*integer*): Threshold for using dense factorization [↔](#)

If processed problem $\leq$ this use dense factorization

Range: [-1, 10000]

Default: -1

Dins (*string*): Whether to try Distance Induced Neighborhood Search [↔](#)

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
both	
off	
often	
on	

diveSolves (*integer*): Diving solve option [↔](#)

If >0 then do up to this many solves. However, the last digit is ignored and used for extra options: 1-3 enables fixing of satisfied integer variables (but not at bound), where 1 switches this off for that dive if the dive goes infeasible, and 2 switches it off permanently if the dive goes infeasible.

Range: [-1, 200000]

Default: 100

DivingCoefficient (*string*): Whether to try Coefficient diving heuristic [↔](#)

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
both	
off	
on	

DivingFractional (*string*): Whether to try Fractional diving heuristic [↔](#)

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: `off`

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
both	
off	
on	

DivingGuided (*string*): Whether to try Guided diving heuristic ↩↪

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: `off`

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
both	
off	
on	

DivingLineSearch (*string*): Whether to try LineSearch diving heuristic ↩↪

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: `off`

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
both	
off	
on	

DivingPseudoCost (*string*): Whether to try Pseudocost diving heuristic ↩↪

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: `off`

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
both	
off	
on	

DivingRandom (*string*): Whether to try Diving heuristics ↩

Synonym: DivingSome

This switches on a random diving heuristic at various times. One may prefer to individually turn diving heuristics on or off. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: `off`

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
both	
off	
on	

DivingVectorLength (*string*): Whether to try Vectorlength diving heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: `off`

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
both	
off	
on	

dualPivot (*string*): Dual pivot choice algorithm ↩

The Dantzig method is simple but its use is deprecated. Steepest is the method of choice and there are two variants which keep all weights updated but only scan a subset each iteration. Partial switches this on while automatic decides at each iteration based on information about the factorization. The PE variants add the Positive Edge criterion. This selects incoming variables to try to avoid degenerate moves. See also option psi.

Default: `automatic`

value	meaning
auto	Same as automatic. This is a deprecated setting.
automatic	
dantzig	
partial	
pedantzig	
pesteepest	
steepest	

dumpsolutions (*string*): name of solutions index.gdx file for writing alternate solutions [↔](#)

The name of a solutions index.gdx file for writing alternate solutions found by CBC. The GDX file specified by this option will contain a set called index that contains the names of GDX files with the individual solutions.

dumpsolutionsmerged (*string*): name of.gdx file for writing all alternate solutions [↔](#)

dwHeuristic (*string*): Whether to try Dantzig Wolfe heuristic [↔](#)

This heuristic is very very compute intensive. It tries to find a Dantzig Wolfe structure and use that. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

Values: before, both, off, on

expensiveStrong (*integer*): Whether to do even more strong branching [↔](#)

Strategy for extra strong branching. 0 is normal strong branching. 1, 2, 4, and 6 does strong branching on all fractional variables if at the root node (1), at depth less than modifier (2), objective equals best possible (4), or at depth less than modifier and objective equals best possible (6). 11, 12, 14, and 16 are like 1, 2, 4, and 6, respectively, but do strong branching on all integer (incl. non-fractional) variables. Values ≥ 100 are used to specify a depth limit (value/100), otherwise 5 is used. If the values ≥ 100 , then above rules are applied to value.

Default: 0

extraVariables (*integer*): Allow creation of extra integer variables [↔](#)

Switches on a trivial re-formulation that introduces extra integer variables to group together variables with same cost.

Range: $[-\infty, \infty]$

Default: 0

factorization (*string*): Which factorization to use [↔](#)

The default is to use the normal CoinFactorization, but other choices are a dense one, OSL's, or one designed for small problems.

Default: normal

Values: dense, normal, osl, simple

feaspump (*string*): Whether to try the Feasibility Pump heuristic [↔](#)

Synonym: feasibilityPump

This heuristic is due to Fischetti, Glover, and Lodi and uses a sequence of LPs to try and get an integer feasible solution. Some fine tuning is available by options passFeasibilityPump and pumpTune. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: on

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
both	
off	
on	

feaspump_artcost (*real*): Costs $\geq$ this treated as artificials in feasibility pump [↔](#)

Synonym: artificialCost

A value of 0.0 means off. Otherwise, variables with costs $\geq$ this are treated as artificial variables and fixed to lower bound in feasibility pump.

Default: 0

feaspump_cutoff (*real*): Fake cutoff for use in feasibility pump [↔](#)

Synonym: pumpCutoff

A value of 0.0 means off. Otherwise, add a constraint forcing objective below this value in feasibility pump

Range: $[-\infty, \infty]$

Default: 0

feaspump_fracbab (*real*): Fraction in feasibility pump [↔](#)

Synonym: fractionforBAB

After a pass in the feasibility pump, variables which have not moved about are fixed and if the preprocessed model is smaller than this fraction of the original problem, a few nodes of branch and bound are done on the reduced problem.

Range: $[1e-05, 1.1]$

Default: 0.5

feaspump_increment (*real*): Fake increment for use in feasibility pump [↔](#)

Synonym: pumpIncrement

A value of 0.0 means off. Otherwise use as absolute increment to cutoff when solution found in feasibility pump

Range: $[-\infty, \infty]$

Default: 0

feaspump_passes (*integer*): How many passes to do in the Feasibility Pump heuristic [↔](#)

Synonym: passFeasibilityPump

Range: $[0, 10000]$

Default: 20

fixOnDj (*real*): Try heuristic based on fixing variables with reduced costs greater than this ↩

If this is set integer variables with reduced costs greater than this will be fixed before branch and bound - use with extreme caution!

Range: $[-\infty, \infty]$

Default: -1

flowCoverCuts (*string*): Whether to use Flow Cover cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: <https://github.com/coin-or/Cgl/wiki/CglFlowCover>

Default: ifmove

Values: forceon, ifmove, off, on, onglobal, root

gamma (*string*): Whether to regularize barrier ↩

Default: off

Values: delta, deltastrong, gamma, gammastrong, off, on, onstrong

gomoryCuts (*string*): Whether to use Gomory cuts ↩

The original cuts - beware of imitations! Having gone out of favor, they are value. Value 'forceon' turns on the cut generator and forces CBC to use it at now more fashionable as LP solvers are more robust and they interact well with other cuts. They will almost always give cuts (although in this executable they are limited as to number of variables in cut). However the cuts may be dense so it is worth experimenting (Long allows any length). Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective

Default: ifmove

Values: forceandglobal, forcelongon, forceon, ifmove, long, off, on, onglobal, root

gomorycuts2 (*string*): Whether to use alternative Gomory cuts ↩

Synonym: GMICuts

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. This version is by Giacomo Nannicini and may be more robust than gomoryCuts.

Default: off

Values: endonly, forcelongon, forceon, ifmove, long, longendonly, longifmove, longroot, off, on, root

greedyHeuristic (*string*): Whether to use a greedy heuristic ↩

This heuristic tries to obtain a feasible solution by just fixing a percentage of variables and then try a small branch and cut run. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: on

Values: before, both, off, on

heuristics (*boolean*): Switches most primal heuristics on or off ↩

Synonym: heuristicsOnOff

This option can be used to switch on or off all heuristics that search for feasible solutions, except for the local tree search, as it dramatically alters the search. Then individual heuristics can be turned off or on.

Default: 1

hOptions (*integer*): Heuristic options ↩

Value 1 stops heuristics immediately if the allowable gap has been reached. Other values are for the feasibility pump - 2 says do exact number of passes given, 4 only applies if an initial cutoff has been given and says relax after 50 passes, while 8 will adapt the cutoff rhs after the first solution if it looks as if the code is stalling.

Range: $[-\infty, \infty]$

Default: 0

idiotCrash (*integer*): Whether to try idiot crash ↩

This is a type of 'crash' which works well on some homogeneous problems. It works best on problems with unit elements and rhs but will do something to any model. It should only be used before the primal simplex algorithm. It can be set to -1 when the code decides for itself whether to use it, 0 to switch off, or $n > 0$ to do n passes.

Range: $[-1, \infty]$

Default: -1

increment (*real*): A valid solution must be at least this much better than last integer solution ↩

Whenever a solution is found the bound on the objective value for new solutions is set to the objective function of the found solution (in a minimization sense) plus this. If it is not set then CBC will try and work one out, e.g. if all objective coefficients are multiples of 0.01 and only integer variables have entries in the objective function, then the increment can be set to 0.01. Be careful if setting this to a negative value!

Range: $[-\infty, \infty]$

Default: GAMS cheat

infeasibilityWeight (*real*): Each integer infeasibility is expected to cost this much ↩

A primitive way of deciding which node to explore next. Satisfying each integer infeasibility is expected to cost this much.

Default: 0

iterlim (*integer*): Maximum number of iterations before stopping ↔

Synonym: maxIterations

For an LP, this is the maximum number of iterations to solve the LP. For a MIP, this option is ignored.

Default: GAMS iterlim

KKT (*boolean*): Whether to use KKT factorization in barrier ↔

Default: 0

knapsackCuts (*string*): Whether to use Knapsack cuts ↔

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: <https://github.com/coin-or/Cgl/wiki/CglKnapsackCover>

Default: ifmove

Values: forceandglobal, forceon, ifmove, off, on, onglobal, root

lagomoryCuts (*string*): Whether to use Lagrangean Gomory cuts ↔

This is a gross simplification of 'A Relax-and-Cut Framework for Gomory's Mixed-Integer Cuts' by Matteo Fischetti & Domenico Salvagnin. This simplification just uses original constraints while modifying objective using other cuts. So you don't use messy constraints generated by Gomory etc. A variant is to allow non messy cuts e.g. clique cuts. So 'only' does this while 'clean' also allows integral valued cuts. 'End' is recommended and waits until other cuts have finished before it does a few passes. The length options for gomory cuts are used.

Default: off

Values: bothaswell, bothaswellroot, bothinstead, cleanaswell, cleanaswellroot, cleaninstead, endboth, endclean, endcleanroot, endonly, endonlyroot, off, onlyaswell, onlyaswellroot, onlyinstead, root

latwomirCuts (*string*): Whether to use Lagrangean TwoMir cuts ↔

This is a Lagrangean relaxation for TwoMir cuts. See lagomoryCuts for description of options.

Default: off

Values: bothaswell, bothinstead, cleanaswell, cleaninstead, endboth, endbothroot, endclean, endcleanroot, endonly, endonlyroot, off, onlyaswell, onlyinstead

liftAndProjectCuts (*string*): Whether to use Lift and Project cuts ↔

These cuts may be expensive to compute. Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: <https://github.com/coin-or/Cgl/wiki/CglLandP>

Default: off

Values: forceon, ifmove, off, on, root

localTreeSearch (*boolean*): Whether to use local tree search when a solution is found ↩

The heuristic is from Fischetti and Lodi and is not really a heuristic although it can be used as one (with limited functionality). It is not switched on when heuristics are switched on.

Default: 0

loglevel (*integer*): amount of output printed by CBC ↩

Default: 1

maxFactor (*integer*): Maximum number of iterations between refactorizations ↩

If this is left at its default value of 200 then CLP will guess a value to use. CLP may decide to re-factorize earlier for accuracy.

Range: $[1, \infty]$

Default: 200

maxsol (*integer*): Maximum number of solutions to save ↩

Synonym: maxSavedSolutions

Maximal number of solutions to store during search and to dump into gdx files if dumpsolutions options is set.

Default: 100

mipstart (*boolean*): whether it should be tried to use the initial variable levels as initial MIP solution ↩

This option controls the use of advanced starting values for mixed integer programs. A setting of 1 indicates that the variable level values should be checked to see if they provide an integer feasible solution before starting optimization.

Default: 0

mirCuts (*string*): Whether to use Mixed Integer Rounding cuts ↩

Synonym: mixedIntegerRoundingCuts

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: <https://github.com/coin-or/Cgl/wiki/CglMixedIntegerRounding2>

Default: ifmove

Values: forceon, ifmove, off, on, onglobal, root

multipleRootPasses (*integer*): Do multiple root passes to collect cuts and solutions [↔](#)

Solve (in parallel, if enabled) the root phase this number of times, each with its own different seed, and collect all solutions and cuts generated. The actual format is aabbcc where aa is the number of extra passes; if bb is non zero, then it is number of threads to use (otherwise uses threads setting); and cc is the number of times to do root phase. The solvers do not interact with each other. However if extra passes are specified then cuts are collected and used in later passes - so there is interaction there. Some parts of this implementation have their origin in idea of Andrea Lodi, Matteo Fischetti, Michele Monaci, Domenico Salvagnin, and Andrea Tramontani.

Default: 0

naiveHeuristics (*string*): Whether to try some stupid heuristic [↔](#)

This is naive heuristics which, e.g., fix all integers with costs to zero!. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
both	
off	
on	

nodeStrategy (*string*): What strategy to use to select the next node from the branch and cut tree [↔](#)

Normally before a feasible solution is found, CBC will choose a node with fewest infeasibilities. Alternatively, one may choose tree-depth as the criterion. This requires the minimal amount of memory, but may take a long time to find the best solution. Additionally, one may specify whether up or down branches must be selected first (the up-down choice will carry on after a first solution has been bound). The default choice 'hybrid' does breadth first on small depth nodes and then switches to 'fewest'.

Default: fewest

Values: depth, downdepth, downfewest, fewest, hybrid, updepth, upfewest

nodlim (*integer*): node limit [↔](#)

Synonyms: maxNodes nodelim

Maximum number of nodes that are enumerated in the Branch and Bound tree search.

Range: $[-1, \infty]$

Default: GAMS nodlim

optca (*real*): Stop when gap between best possible and best less than this [↔](#)

Synonym: allowableGap

If the gap between best known solution and the best possible solution is less than this value, then the search will be terminated. Also see ratioGap.

Default: GAMS optca

optcr (*real*): Stop when gap between best possible and best known is less than this fraction of larger of two ↩

Synonym: ratioGap

If the gap between the best known solution and the best possible solution is less than this fraction of the objective value at the root node then the search will terminate. See 'allowableGap' for a way of using absolute value rather than fraction.

Default: GAMS optcr

OrbitalBranching (*string*): Whether to try orbital branching ↩

This switches on Orbital branching. Value 'on' just adds orbital, 'strong' tries extra fixing in strong branching.

Default: off

Values: force, off, on, simple, strong

parallelmode (*string*): whether to run opportunistic or deterministic ↩

Determines whether a parallel MIP search (threads > 1) should be done in a deterministic (i.e., reproducible) way or in a possibly faster but not necessarily reproducible way

Default: deterministic

Values: deterministic, opportunistic

passPresolve (*integer*): How many passes in presolve ↩

Normally Presolve does 10 passes but you may want to do less to make it more lightweight or do more if improvements are still being made. As Presolve will return if nothing is being taken out, you should not normally need to use this fine tuning.

Range: [-200, 100]

Default: 5

perturbation (*boolean*): Whether to perturb the problem ↩

Perturbation helps to stop cycling, but CLP uses other measures for this. However, large problems and especially ones with unit elements and unit right hand sides or costs benefit from perturbation. Normally CLP tries to be intelligent, but one can switch this off.

Default: 1

pivotAndComplement (*string*): Whether to try Pivot and Complement heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

Values: before, both, off, on

pivotAndFix (*string*): Whether to try Pivot and Fix heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
both	
off	
on	

preprocess (*string*): Whether to use integer preprocessing ↩

This tries to reduce size of model in a similar way to presolve and it also variables. tries to strengthen the model - this can be very useful and is worth trying. Value 'save' saves the presolved problem to a file presolved.mps. Value 'equal' will turn inequality-cliques into equalities. Value 'sos' lets CBC search for rows with upper bound 1 and where all nonzero coefficients are 1 and creates special ordered sets if the sets are not overlapping and all integer variables (except for at most one) are in the sets. Value 'trysos' is same as 'sos', but allows any number of integer variables outside of sets. Value 'equalall' lets CBC turn all valid inequalities into equalities by adding integer slack

Default: `sos`

Values: `aggregate`, `equal`, `equalall`, `forcesos`, `off`, `on`, `save`, `sos`, `stopaftersaving`, `strategy`, `trysos`

presolve (*string*): Whether to presolve problem ↩

Presolve analyzes the model to find such things as redundant equations, equations which fix some variables, equations which can be transformed into bounds, etc. For the initial solve of any problem this is worth doing unless one knows that it will have no effect. Option 'on' will normally do 5 passes, while using 'more' will do 10.

Default: `on`

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
more	
off	
on	

primalPivot (*string*): Primal pivot choice algorithm ↩

The Dantzig method is simple but its use is deprecated. Exact devex is the method of choice and there are two variants which keep all weights updated but only scan a subset each iteration. Partial switches this on while 'change' initially does 'dantzig' until the factorization becomes denser. This is still a work in progress. The PE variants add the Positive Edge criterion. This selects incoming variables to try to avoid degenerate moves. See also Towhidi, M., Desrosiers, J., Soumis, F., The positive edge criterion within COIN-OR's CLP; Omer, J., Towhidi, M., Soumis, F., The positive edge pricing rule for the dual simplex.

Default: `automatic`

value	meaning
auto	Same as automatic. This is a deprecated setting.

value	meaning
automatic	
change	
dantzig	
exact	
partial	
pedantzig	
pesteepest	
sprint	
steepest	

primalWeight (*real*): Initially algorithm acts as if it costs this much to be infeasible ↩

The primal algorithm in Clp is a single phase algorithm as opposed to a two phase algorithm where you first get feasible then optimal. So Clp is minimizing this weight times the sum of primal infeasibilities plus the true objective function (in minimization sense). Too high a value may mean more iterations, while too low a value means the algorithm may iterate into the wrong directory for long and then has to increase the weight in order to get feasible.

Range: $[1e-20, \infty]$

Default: `1e+10`

printfrequency (*integer*): frequency of status prints ↩

Controls the number of nodes that are evaluated between status prints.

Default: `0`

probingCuts (*string*): Whether to use Probing cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut 'forceonbutstrong' is like 'forceonstrong', but does only probing (column tree (see cutDepth on how to fine tune the behavior)). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Value 'forceOnBut' turns on probing and forces CBC to do probing at every node, but does only probing, not strengthening etc. Value 'strong' forces CBC to strongly do probing at every node, that is, also when CBC would usually turn it off because it hasn't found something. Value

Default: `ifmove`

Values: `forceon`, `forceonbut`, `forceonbutstrong`, `forceonglobal`, `forceonstrong`, `ifmove`, `off`, `on`, `onglobal`, `root`, `strongroot`

proximitySearch (*string*): Whether to do proximity search heuristic ↩

This heuristic looks for a solution close to the incumbent solution (Fischetti heuristic only if option doHeuristics is used. Value 'both' means to use the and Monaci, 2012). The idea is to define a sub-MIP without additional constraints but with a modified objective function intended to attract the search in the proximity of the incumbent. The approach works well for 0-1 MIPs whose solution landscape is not too irregular (meaning there is reasonable probability of finding an improved solution by flipping a small number of binary variables), in particular when it is applied to the first heuristic solutions found at the root node. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the

Default: `off`

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

psi (*real*): Two-dimension pricing factor for Positive Edge criterion [↔](#)

The Positive Edge criterion has been added to select incoming variables to try Soumis, F., The positive edge criterion within COIN-OR's CLP; Omer, J., and avoid degenerate moves. Variables not in the promising set have their infeasibility weight multiplied by psi, so 0.01 would mean that if there were any promising variables, then they would always be chosen, while 1.0 effectively switches the algorithm off. There are two ways of switching this feature on. One way is to set psi to a positive value and then the Positive Edge criterion will be used for both primal and dual simplex. The other way is to select PEsteepest in dualpivot choice (for example), then the absolute value of psi is used. Code donated by Jeremy Omer. See Towhidi, M., Desrosiers, J.,

Range: $[-1.1, 1.1]$

Default: -0.5

randomizedRounding (*string*): Whether to try randomized rounding heuristic [↔](#)

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
both	
off	
on	

randomSeedCbc (*integer*): Random seed for Cbc [↔](#)

Synonym: randomCbcSeed

Allows initialization of the random seed for pseudo-random numbers used in heuristics such as the Feasibility Pump to decide whether to round up or down. The special value of 0 lets Cbc use the time of the day for the initial seed.

Range: $[-1, \infty]$

Default: -1

randomSeedClp (*integer*): Random seed for Clp ↩

Synonym: randomSeed

Initialization of the random seed for pseudo-random numbers used to break ties in degenerate problems. This may yield a different continuous optimum and, in the context of Cbc, different cuts and heuristic solutions. The special value of 0 lets CLP use the time of the day for the initial seed.

Default: 1234567

reduceAndSplitCuts (*string*): Whether to use Reduce-and-Split cuts ↩

These cuts may be expensive to generate. Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: <https://github.com/coin-or/Cgl/wiki/CglRedSplit>

Default: off

Values: forceon, ifmove, off, on, root

reduceAndSplitCuts2 (*string*): Whether to use Reduce-and-Split cuts - style 2 ↩

Synonym: reduce2AndSplitCuts

This switches on reduce and split cuts (either at root or in entire tree). This version is by Giacomo Nannicini based on Francois Margot's version. Standard setting only uses rows in tableau ≤ 256 , long uses all. These cuts may be expensive to generate. See option cuts for more information on the possible values.

Default: off

Values: longon, longroot, off, on, root

Rens (*string*): Whether to try Relaxation Enforced Neighborhood Search ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve. Value 'on' just does 50 nodes. 200, 1000, and 10000 does that many nodes.

Default: off

value	meaning

residualCapacityCuts (*string*): Whether to use Residual Capacity cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: <https://github.com/coin-or/Cgl/wiki/CglResidualCapacity>

Default: off

Values: forceon, ifmove, off, on, root

reslim (*real*): maximum seconds ↩

Synonym: seconds

Range: $[-1, \infty]$

Default: GAMS reslim

Rins (*string*): Whether to try Relaxed Induced Neighborhood Search ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

value	meaning
0	Same as off. This is a deprecated setting.

roundingHeuristic (*string*): Whether to use simple (but effective) Rounding heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: on

value	meaning
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.
before	
both	
off	
on	

scaling (*string*): Whether to scale problem ↩

Scaling can help in solving problems which might otherwise fail because of lack of accuracy. It can also reduce the number of iterations. It is not applied if the range of elements is small. When the solution is evaluated in the unscaled problem, it is possible that small primal and/or dual infeasibilities occur. Option 'equilibrium' uses the largest element for scaling. Option 'geometric' uses the squareroot of the product of largest and smallest element. Option 'auto' let CLP choose a method that gives the best ratio of the largest element to the smallest one.

Default: `automatic`

value	meaning
<code>auto</code>	Same as automatic. This is a deprecated setting.
<code>automatic</code>	
<code>dynamic</code>	
<code>equilibrium</code>	
<code>geometric</code>	
<code>off</code>	
<code>rowsonly</code>	

smallFactorization (*integer*): Threshold for using small factorization ↩

If processed problem $\leq$ this use small factorization

Range: $[-1, 10000]$

Default: `-1`

sollim (*integer*): Maximum number of feasible solutions to get ↩

Synonym: `maxSolutions`

Range: $[1, \infty]$

Default: `maxint`

solvefinal (*boolean*): final solve of MIP with fixed discrete variables ↩

Whether the MIP with discrete variables fixed to solution values should be solved after CBC finished.

Default: `1`

solvetrace (*string*): name of trace file for solving information ↩

Name of file for writing solving progress information during solve.

solvetracenodefREQ (*integer*): frequency in number of nodes for writing to solve trace file ↩

Default: `100`

solvetracetimefreq (*real*): frequency in seconds for writing to solve trace file ↩

Default: `5`

sosPrioritize (*string*): How to deal with SOS priorities ↩

This sets priorities for SOS. Values 'high' and 'low' just set a priority relative to the for integer variables. Value 'orderhigh' gives first highest priority to the first SOS and integer variables a low priority. Value 'orderlow' gives integer variables a high priority then SOS in order.

Default: `off`

Values: `high`, `low`, `off`, `orderhigh`, `orderlow`

sparseFactor (*boolean*): Whether factorization treated as sparse ↩

Default: `1`

special (*string*): options passed unseen to CBC ↩

This parameter let you specify CBC options which are not supported by the GAMS/CBC interface. The string value given to this parameter is split up into parts at each space and added to the array of parameters given to CBC (in front of the `-solve` command). Hence, you can use it like the command line parameters for the CBC standalone version.

sprintCrash (*integer*): Whether to try sprint crash ↩

Synonym: `sifting`

For long and thin problems this method may solve a series of small problems created by taking a subset of the columns. The idea as 'Sprint' was introduced by J. Forrest after an LP code of that name of the 60's which tried the same tactic (not totally successfully). CPLEX calls it 'sifting'. -1 lets CLP automatically choose the number of passes, 0 is off, n is number of passes

Range: $[-1, \infty]$

Default: `-1`

startalg (*string*): LP solver for root node ↩

Determines the algorithm to use for an LP or the initial LP relaxation if the problem is a MIP.

Default: `dual`

value	meaning
<code>barrier</code>	Primal-dual predictor-corrector algorithm
<code>dual</code>	Dual Simplex algorithm
<code>primal</code>	Primal Simplex algorithm

strategy (*integer*): Switches on groups of features ↩

This turns on newer features. Use 0 for easy problems, 1 is default, 2 is aggressive. 1 uses Gomory cuts with a tolerance of 0.01 at the root node, does a possible restart after 100 nodes if many variables could be fixed, activates a diving and RINS heuristic, and makes the feasibility pump more aggressive.

Range: $[0, 2]$

Default: `1`

strongBranching (*integer*): Number of variables to look at in strong branching ↩

In order to decide which variable to branch on, the code will choose up to this number of unsatisfied variables to try minimal up and down branches on. Then the most effective one is chosen. If a variable is branched on many times then the previous average up and down costs may be used - see also option `trustPseudoCosts`.

Default: 5

substitution (*integer*): How long a column to substitute for in presolve ↩

Normally Presolve gets rid of 'free' variables when there are no more than 3 coefficients in a row. If you increase this, the number of rows may decrease but the number of coefficients may increase.

Range: [0, 10000]

Default: 3

threads (*integer*): Number of threads to try and use ↩

Range: [1, 99]

Default: `GAMS threads`

tol_dual (*real*): For an optimal solution no dual infeasibility may exceed this value ↩

Synonym: `dualTolerance`

Normally the default tolerance is fine, but one may want to increase it a bit if the dual simplex algorithm seems to be having a hard time. One method which can be faster is to use a large tolerance e.g. $1.0\text{e-}4$ and the dual simplex algorithm and then to clean up the problem using the primal simplex algorithm with the correct tolerance (remembering to switch off presolve for this final short clean up phase).

Range: [$1\text{e-}20$, ∞]

Default: $1\text{e-}07$

tol_integer (*real*): For a feasible solution no integer variable may be more than this away from an integer value ↩

Synonym: `integerTolerance`

Beware of setting this smaller than the primal feasibility tolerance.

Range: [$1\text{e-}20$, 0.5]

Default: $1\text{e-}07$

tol_presolve (*real*): Tolerance to use in presolve ↩

Synonym: `preTolerance`

One may want to increase this tolerance if presolve says the problem is infeasible and one has awkward numbers and is sure that the problem is really feasible.

Range: [$1\text{e-}20$, ∞]

Default: $1\text{e-}08$

tol_primal (*real*): For a feasible solution no primal infeasibility, i.e., constraint violation, may exceed this value ↩

Synonym: primalTolerance

Normally the default tolerance is fine, but one may want to increase it a bit if the primal simplex algorithm seems to be having a hard time.

Range: $[1\text{e-}20, \infty]$

Default: $1\text{e-}07$

trustPseudoCosts (*integer*): Number of branches before we trust pseudocosts ↩

Using strong branching computes pseudo-costs. This parameter determines after how many branches for a variable we just trust the pseudo costs and do not do any more strong branching.

Range: $[-3, \infty]$

Default: 10

twoMirCuts (*string*): Whether to use Two phase Mixed Integer Rounding cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: <https://github.com/coin-or/Cgl/wiki/CglTwomir>

Default: root

Values: forceandglobal, forcelongon, forceon, ifmove, off, on, onglobal, root

VndVariableNeighborhoodSearch (*string*): Whether to try Variable Neighborhood Search ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

Values: before, both, intree, off, on

vubheuristic (*integer*): Type of VUB heuristic ↩

This heuristic tries and fix some integer variables.

Range: $[-2, 20]$

Default: -1

writemps (*string*): create MPS file for problem ↩

Write the problem formulation in MPS format. The parameter value is the name of the MPS file.

zeroHalfCuts (*string*): Whether to use zero half cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. This implementation was written by Alberto Caprara.

Default: ifmove

Values: forceon, ifmove, off, on, onglobal, root

5.11 CONOPT

Arne Drud, ARKI Consulting and Development A/S, Bagsvaerd, Denmark

5.11.1 Introduction

Nonlinear models created with GAMS must be solved with a nonlinear programming (NLP) algorithm. Currently, there is a large number of different solvers available and the number is growing.

The most important distinction between the solvers is whether they attempt to find a local or a global solution. Solvers that attempt to find a global solution (so called Global Solvers) can usually not solve very large models. As a contrast most Local Solvers can work with much larger models, and models with over 10,000 variables and constraints are not unusual. If the model has the right mathematical properties, e.g. is convex, then Local Solvers will find a global optimum. Unfortunately, the mathematical machinery for testing whether a general NLP model is convex or not has not yet been developed (and is expected to be in the class of hard problems).

It is almost impossible to predict how difficult it is to solve a particular model with a particular algorithm, especially for NLP models, so GAMS cannot select the best algorithm for you automatically. When GAMS is installed you must select one of the nonlinear programming algorithms as the default solver for NLP models. If you want to switch between algorithms for a particular model you may add the statement `Option NLP = <solvrname>`, in your GAMS source file before the `Solve` statement, you may add `NLP = <solvrname>` on the GAMS command line or by rerunning the `gamsinst` program.

The only reliable way to find which solver to use for a particular class of models is so far to experiment. However, there are a few rules of thumb:

GAMS/CONOPT is well suited for models with very nonlinear constraints. If you experience that a solver has problems maintaining feasibility during the optimization you should try CONOPT. On the other hand, if you have a model with few nonlinearities outside the objective function then other solvers could be the best solver.

GAMS/CONOPT has a fast method for finding a first feasible solution that is particularly well suited for models with few degrees of freedom. If you have a model with roughly the same number of constraints as variable you should try CONOPT. CONOPT can also be used to solve square systems of equations without an objective function corresponding to the GAMS model class CNS - Constrained Nonlinear System.

GAMS/CONOPT can use second derivatives. If the number of variables is much larger than the number of constraints CONOPT will use second derivatives and overall progress can be considerably faster than for MINOS or SNOPT. IPOPT and KNITRO will also use second derivatives, but the method is very different and it is not possible to predict which solver will be better.

GAMS/CONOPT has a preprocessing step in which recursive equations and variables are solved and removed from the model. If you have a model where many equations can be solved one by one then CONOPT will take advantage of this property. Similarly, intermediate variables only used to define objective terms are eliminated from the model and the constraints are moved into the objective function.

GAMS/CONOPT has many built-in tests and messages, and many models that can and should be improved by the modeler are rejected with a constructive message. CONOPT is therefore also a helpful debugging tool during model development. The best solver for the final, debugged model may or may not be CONOPT.

GAMS/CONOPT has been designed for large and sparse models. This means that both the number of variables and equations can be large. Indeed, NLP models with over 100,000 equations and variables have been solved successfully, and CNS models with over 1,000,000 equations and variables have also

been solved. The components used to build CONOPT have been selected under the assumptions that the model is sparse, i.e. that most functions only depend on a small number of variables. CONOPT can also be used for denser models, but the performance will suffer significantly.

GAMS/CONOPT is designed for models with smooth functions, but it can also be applied to models that do not have differentiable functions, in GAMS called DNLP models. However, CONOPT will use the same algorithm used for a real NLP model and it will search for a point that satisfies standard first-order optimality conditions without taking into account that parts of the model could be non-smooth or non-differentiable. The lack of smoothness may confuse the algorithm in CONOPT causing slow convergence, and a point that satisfies standard first-order optimality conditions may not even exist. There are therefore no guaranties whatsoever for this class of models. If CONOPT terminates with a locally optimal solution then the solution will indeed be locally optimal. However, you will sometimes get termination messages like "Convergence too slow" or "No change in objective although the reduced gradient is greater than the tolerance" that indicate unsuccessful termination. The final point may or may not be locally optimal. If possible, you should try to reformulate a DNLP model to an equivalent or approximately equivalent form as described in section [NLP and DNLP Models](#).

Most modelers should not be concerned with algorithmic details such as choice of algorithmic sub-components or tolerances. CONOPT has considerable build-in logic that selects a solution approach that seems to be best suited for the type of model at hand, and the approach is adjusted dynamically as information about the behavior of the model is collected and updated. The description of the CONOPT algorithm has therefore been moved to an appendix ([Appendix A](#)) and most modelers can skip it. However, if you are solving very large or complex models or if you are experiencing solution difficulties you may benefit from using non-standard tolerances or options, in which case you will need some understanding of what CONOPT is doing to your model. Some guidelines for selecting options can be found at the end of [Appendix A](#) and a list of all options and tolerances is shown in [Appendix B](#).

The main text of this User's Guide will give a short overview over the iteration output you will see on the screen (section [Iteration Output](#)), and explain the termination messages (section [GAMS/CONOPT Termination Messages](#)). We will then discuss function evaluation errors (section [Function Evaluation Errors](#)), the use of options (section [The CONOPT Options File](#)), and give a CONOPT perspective on good model formulation including topics such as initial values and bounds, simplification of expressions, and scaling (section [Hints on Good Model Formulation](#)). Finally, we will discuss the difference between NLP and DNLP models (section [NLP and DNLP Models](#)).

5.11.2 Iteration Output

On most machines you will by default get a logline on your screen or terminal at regular intervals. The iteration log may look something like this:

```
CONOPT 3          Jul  4, 2012 23.9.4 WEX 35892.35906 WEI x86_64/MS Windows
```

247	4		1.0128171043E+00	5.7E-08	13				

** Optimal solution. Reduced gradient less than tolerance.

The first few lines identify the version of CONOPT you use.

The first iterations have a special interpretation: iteration 0 represents the initial point exactly as received from GAMS, iteration 1 represent the point that is the result of CONOPT's pre-processing, and iteration 2 represents the same point after scaling (even if scaling is turned off).

The remaining iterations are characterized by the value of "Phase" in column 2. The model is infeasible during Phase 0, 1, and 2 and the Sum of Infeasibilities in column 4 (labeled "Infeasibility") is being minimized; the model is feasible during Phase 3 and 4 and the actual objective function, also shown in column 4 (now labeled "Objective"), is minimized or maximized. Phase 0 iterations are Newton-like iterations. They are very cheap so you should not be concerned if there are many of these Phase 0 iterations. During Phase 1 and 3 the model behaves almost linearly and CONOPT applies special linear iterations that take advantage of the linearity. These iterations are sometimes augmented with some inner "Sequential Linear Programming" (SLP) iterations, indicated by a number of inner SLP iterations in the "InItr" column. During Phase 2 and 4 the model behaves more nonlinear and most aspects of the iterations are therefore changed: the line search is more elaborate, and CONOPT needs second order information to improve the convergence. For small and simple models CONOPT will approximate second order information as a byproduct of the line searches. For larger and more complex models CONOPT will

use some inner "Sequential Quadratic Programming" (SQP) iterations based on exact second derivatives. These SQP iterations are identified by the number of inner SQP iterations in the "InItr" column.

The column "NSB" for Number of SuperBasics defines the degree of freedom or the dimension of the current search space, and "rgmax" measures the largest reduced gradient among the non-optimal variables. Rgmax should eventually converge towards zero, but convergence is not expected to be monotone. The last two columns labeled "MX" and "OK" gives information about the line search: OK = T means that the line search was well-behaved, and OK = F means that the line search was terminated before an optimal step length was found because it was not possible to find a feasible solution for large step lengths. MX = T means that the line search was terminated by a variable reaching a bound (always combined with OK = T), and MX = F means that the step length was determined by nonlinearities. If OK = T then the step length was optimal; if OK = F then the constraints were too nonlinear to allow CONOPT to make a full optimal step.

5.11.3 GAMS/CONOPT Termination Messages

GAMS/CONOPT may terminate in a number of ways. This section will show most of the termination messages and explain their meaning. It will also show the Model Status returned to GAMS in `<model>.ModelStat`, where `<model>` represents the name of the GAMS model. The Solver Status returned in `<model>.SolveStat` will be given if it is different from 1 (Normal Completion). We will in all cases first show the message from CONOPT followed by a short explanation. The first 4 messages are used for optimal solutions and CONOPT will return `ModelStat = 2` (Locally Optimal), except as noted below:

```
** Optimal solution. There are no superbasic variables.
```

The solution is a locally optimal corner solution. The solution is determined by constraints only, and it is usually very accurate. In some cases CONOPT can determine that the solution is globally optimal and it will return `ModelStat = 1` (Optimal).

```
** Optimal solution. Reduced gradient less than tolerance.
```

The solution is a locally optimal interior solution. The largest component of the reduced gradient is less than the tolerance `rtredg` with default value `1.e-7`. The value of the objective function is very accurate while the values of the variables are less accurate due to a flat objective function in the interior of the feasible area.

```
** Optimal solution. The error on the optimal objective function  
value estimated from the reduced gradient and the estimated  
Hessian is less than the minimal tolerance on the objective.
```

The solution is a locally optimal interior solution. The largest component of the reduced gradient is larger than the tolerance `rtredg`. However, when the reduced gradient is scaled with information from the estimated Hessian of the reduced objective function the solution seems optimal. For this to happen the objective must be large or the reduced objective must have large second derivatives so it is advisable to scale the model. See the sections on "Scaling" and "Using the Scale Option in GAMS" for details on how to scale a model.

```
** Optimal solution. Convergence too slow. The change in  
objective has been less than xx.xx for xx consecutive  
iterations.
```

CONOPT stops with a solution that seems optimal. The solution process is stopped because of slow progress. The largest component of the reduced gradient is greater than the optimality tolerance `rtredg`, but less than `rtredg` multiplied by the largest Jacobian element divided by 100. The model must have large derivatives so it is advisable to scale it.

The four messages above all exist in versions where "Optimal" is replaced by "Infeasible" and ModelStat will be 5 (Locally Infeasible) or 4 (Infeasible). The infeasible messages indicate that a Sum of Infeasibility objective function is locally minimal, but positive. If the model is convex it does not have a feasible solution; if the model is non-convex it may have a feasible solution in a different region. See the section on "Initial Values" for hints on what to do.

```
** Feasible solution. Convergence too slow. The change in
    objective has been less than xx.xx for xx consecutive
    iterations.

** Feasible solution. The tolerances are minimal and
    there is no change in objective although the reduced
    gradient is greater than the tolerance.
```

The two messages above tell that CONOPT stops with a feasible solution. In the first case the solution process is very slow and in the second there is no progress at all. However, the optimality criteria have not been satisfied. These messages are accompanied by ModelStat = 7 (Feasible Solution) and SolveStat = 4 (Terminated by Solver). The problem can be caused by discontinuities if the model is of type DNLP; in this case you should consider alternative, smooth formulations as discussed in section [NLP and DNLP Models](#). The problem can also be caused by a poorly scaled model. See section [Scaling](#) for hints on model scaling. Finally, it can be caused by stalling as described in section [Stalling in Appendix A](#). The two messages also exist in a version where "Feasible" is replaced by "Infeasible". ModelStat is in this case 6 (Intermediate Infeasible) and SolveStat is still 4 (Terminated by Solver); these versions tell that CONOPT cannot make progress towards feasibility, but the Sum of Infeasibility objective function does not have a well defined local minimum.

```
<var>: The variable has reached infinity

** Unbounded solution. A variable has reached 'infinity'.
    Largest legal value (Rtmaxv) is xx.xx
```

CONOPT considers a solution to be unbounded if a variable exceeds the indicated value of `rtmaxv` (default 1.e10) and it returns with ModelStat = 3 (Unbounded). The check for unboundedness is done at every iteration which means that CONOPT will stop if an intermediate solution has a variable that is very large, even if none of the variables in the optimal solution have large values. Check whether the solution appears unbounded or the problem is caused by the scaling of the unbounded variable "`<var>`" mentioned in the first line of the message. If the model seems correct you are advised to scale it. There is also a lazy solution: you can increase the largest legal value, `rtmaxv`, as mentioned in the section on options. However, you will pay through reduced reliability or increased solution times. Unlike LP models, where an unbounded model is recognized by an unbounded ray and the iterations are stopped far from "infinity", CONOPT will actually have to make a line search and move to a region with large values of the variables. This may lead to bad scaling and to many different kinds of tolerance and roundoff problems, including problems of determining whether a solution is feasible or not.

The message above exists in a version where "Unbounded" is replaced by "Infeasible" and ModelStat is 5 (Locally Infeasible). You may also see a message like

```
<var>: Free variable becomes too large

** Infeasible solution. A free variable exceeds the allowable
    range. Current value is 1.02E+10 and current upper bound
    (Rtmaxv) is 1.00E+10
```

These two messages indicate that some variables become very large before a feasible solution has been found. You should again check whether the problem is caused by the scaling of the unbounded variable "<var>" mentioned in the first line of the message. If the model seems correct you should scale it.

```
** The time limit has been reached.
```

The time or resource limit defined in GAMS, either by default (usually 1000 seconds) or by `Option ResLim = xx;` or `<model>.ResLim = xx;` statements, has been reached. CONOPT will return with `SolveStat = 3` (Resource Interrupt) and `ModelStat` either 6 (Locally Infeasible) or 7 (Feasible Solution).

```
** The iteration limit has been reached.
```

The iteration limit defined in GAMS, either by default (usually 2000000000 iterations) or by `Option IterLim = xx;` or `<model>.IterLim = xx;` statements, has been reached. CONOPT will return with `SolveStat = 2` (Iteration Interrupt) and `ModelStat` either 6 (Locally Infeasible) or 7 (Feasible Solution).

```
** Domain errors in nonlinear functions.
    Check bounds on variables.
```

The number of function evaluation errors has reached the limit defined in GAMS by `Option DomLim = xx;` or `<model>.DomLim = xx;` statements or the default limit of 0 function evaluation errors. CONOPT will return with `SolveStat = 5` (Evaluation Error Limit) and `ModelStat` either 6 (Locally Infeasible) or 7 (Feasible Solution). See more details in section [Function Evaluation Errors](#).

```
** An initial derivative is too large (larger than Rtmaxj= xx.xx)
    Scale the variables and/or equations or add bounds.
```

```
<var> appearing in
<equ>: Initial Jacobian element too large = xx.xx
```

and

```
** A derivative is too large (larger than Rtmaxj= xx.xx).
    Scale the variables and/or equations or add bounds.
```

```
<var> appearing in
<equ>: Jacobian element too large = xx.xx
```

These two messages appear if a derivative or Jacobian element is very large, either in the initial point or in a later intermediate point. The relevant variable and equation pair(s) will show you where to look. A large derivative means that the function changes very rapidly even after a very small change in the variable and it will most likely create numerical problems for many parts of the optimization algorithm. Instead of attempting to solve a model that most likely will fail, CONOPT will stop and you are advised to adjust the model if at all possible.

If the offending derivative is associated with a $\text{Log}(x)$ or $1/x$ term you may try to increase the lower bound on x . If the offending derivative is associated with an $\text{Exp}(x)$ term you must decrease the upper bound on x . You may also try to scale the model, either manually or using the `variable.Scale` and/or `equation.Scale` option in GAMS as described in section [Scaling](#). There is also in this case a lazy solution: increase the limit on Jacobian elements, `rtmaxj`; however, you will pay through reduced reliability or longer solution times.

In addition to the messages shown above you may see messages like

```
** An equation in the pre-triangular part of the model cannot be
solved because the critical variable is at a bound.
```

```
** An equation in the pre-triangular part of the model cannot be
solved because of too small pivot.
```

or

```
** An equation is inconsistent with other equations in the
pre-triangular part of the model.
```

These messages containing the word "Pre-triangular" are all related to infeasibilities identified by CONOPT's pre-processing stage and they are explained in detail in [section Iteration 1: Preprocessing](#) in [Appendix A](#).

Usually, CONOPT will be able to estimate the amount of memory needed for the model based on statistics provided by GAMS. However, in some cases with unusual models, e.g. very dense models or very large models, the estimate will be too small and you must request more memory yourself using a statement like `<model>.WorkFactor = x.x;` or `<model>.Workspace = xx;` in GAMS or by adding `WorkFactor=xx` to the command line call of GAMS. The message you will see is similar to the following:

```
** FATAL ERROR ** Insufficient memory to continue the
optimization.
```

```
You must request more memory.
Current   CONOPT space = 0.29 Mbytes
Estimated CONOPT space = 0.64 Mbytes
Minimum   CONOPT space = 0.33 Mbytes
```

```
CONOPT time Total           0.109 seconds
  of which: Function evaluations 0.000 = 0.0%
           1st derivative evaluations 0.000 = 0.0%
```

The text after "Insufficient memory to" may be different; it says something about where CONOPT ran out of memory. If the memory problem appears during model setup the message will be accompanied by `SolveStat = 13` (System Failure) and `ModelStat = 13` (Error No Solution) and CONOPT will not return any values. If the memory problem appears later during the optimization `SolveStat` will be 11 (Internal Solver Failure) and `ModelStat` will be either 6 (Intermediate Infeasible) or 7 (Feasible Solution) and CONOPT will return primal solution values. The marginals of both equations and variables will be zero or EPS.

It is recommended that you use the `WorkFactor` option if you must change the amount of memory. The same number will usually work for a whole family of models. If you prefer to use `Workspace`, the GAMS `Workspace` option corresponds to the amount of memory, measured in Mbytes.

A new termination message has been added from version 3.16C:

```
** Feasible solution. The solution process has been terminated
because intermediate results have become NaN (Not A Number).
```

and similar with Infeasible. To prevent non-sensible results and/or infinite loops in special degenerate cases CONOPT has added checks for internal intermediate results being NaN (Not A Number) or very large. If this happens CONOPT will try to change some tolerances and try to continue the optimization. If this attempt fails CONOPT will stop and return the message above. The solver status will return 4 "Terminated by Solver" and model status 6 or 7, "Intermediate Infeasible" or "Intermediate Feasible." [Section Overflow and NaN \(Not A Number\)](#) in [Appendix A](#) has more details on the sources of NaN and the actions that can be taken by the user and by CONOPT.

5.11.4 Function Evaluation Errors

Many of the nonlinear functions available with GAMS are not defined for all values of their arguments. Log is not defined for negative arguments, Exp overflows for large arguments, and division by zero is illegal. To avoid evaluating functions outside their domain of definition you should add reasonable variable bounds. CONOPT will in return guarantee that the nonlinear functions never are evaluated with variables outside their bounds.

In some cases bounds are not sufficient, e.g. in the expression $\text{Log}(\text{Sum}(i, x(i)))$: in some models each individual x should be allowed to become zero, but the Sum should not. In this case you should introduce an intermediate variable and an extra equation, e.g. `xSumDef .. xSum =E= sum(i,x(i));` add a lower bound on `xSum`; and use `xSum` as the argument to the Log function. See section [Simple Expressions](#) for additional comments on this topic.

Whenever a nonlinear function is called outside its domain of definition, GAMS' function evaluator will intercept the function evaluation error and prevent the system to crash. GAMS will replace the undefined result by some appropriate real number, and it will make sure the error is reported to the modeler as part of the standard solution output in the GAMS listing file. GAMS will also report the error to CONOPT, so CONOPT can try to correct the problem by backtracking to a safe point. Finally, CONOPT will be instructed to stop after `DomLim` errors.

During Phase 0, 1, and 3 CONOPT will often use large steps as the initial step in a line search and functions will very likely be called with some of the variables at their lower or upper bound. You are therefore likely to get a division-by-zero error if your model contains a division by x and x has a lower bound of zero. And you are likely to get an exponentiation overflow error if your model contains $\text{Exp}(x)$ and x has no upper bound. However, CONOPT will usually not get trapped in a point outside the domain of definition for the model. When GAMS' function evaluator reports that a point is "bad", CONOPT will decrease the step length, and it will for most models be able to recover and continue to an optimal solution. It is therefore safe to use a large value for `DomLim` instead of GAMS default value of 0.

CONOPT may get stuck in some cases, for example because there is no previous point to backtrack to, because "bad" points are very close to "reasonable" feasible points, or because the derivatives are not defined in a feasible point. The more common messages are:

```

** Fatal Error **  Function error in initial point in Phase 0
                    procedure.

** Fatal Error **  Function error after small step in Phase 0
                    procedure.

** Fatal Error **  Function error very close to a feasible point.

** Fatal Error **  Function error while reducing tolerances.

** Fatal Error **  Function error in Pre-triangular equations.

** Fatal Error **  Function error after solving Pre-triangular
                    equations.

** Fatal Error **  Function error in Post-triangular equation.

```

In the first four cases you must either add better bounds or define better initial values. If the problem is related to a pre- or post-triangular equation as shown by the last three messages then you can turn part of the pre-processing off as described in section [Iteration 1: Preprocessing](#) in [Appendix A](#). However, this may make the model harder to solve, so it is usually better to add bounds and/or initial values.

5.11.5 The CONOPT Options File

CONOPT has been designed to be self-tuning. Most tolerances are dynamic. As an example: The feasibility of a constraint is always judged relative to the dual variable on the constraint and relative to the expected change in objective in the coming iteration. If the dual variable is large then the constraint must be satisfied with a small tolerance, and if the dual variable is small then the tolerance is larger. When the expected change in objective in the first iterations is large then the feasibility tolerances are also large. And when we approach the optimum and the expected change in objective becomes smaller then the feasibility tolerances become smaller.

Because of the self-tuning nature of CONOPT you should in most cases be well off with default tolerances. If you do need to change some tolerances, possibly following the advice in [Appendix A](#), it can be done in the CONOPT Options file. The name of the CONOPT Options file is on most systems "conopt.opt". You must tell the solver that you want to use an options file with the statement `<model>.OptFile = 1` in your GAMS source file before the Solve statement or with `OptFile = 1` on the command line.

The format of the CONOPT Options file consists in its simplest form of a number of lines like these:

```
rtmaxv = 1.e12
lfnsup = 500
```

The value must be written using legal GAMS format, i.e. a real number may contain an optional E exponent, but a number may not contain blanks. The value must have the same type as the option, i.e. real options must be assigned real values, integer options must be assigned integer values, and logical options must be assigned logical values. The logical value representing true are **true**, **t**, **yes**, or **1**, and the logical values representing false are **false**, **f**, **no**, or **0**.

In previous versions of CONOPT you could add "SET" in front of the option assignment. This is no longer supported. You can still replace the equal sign with `:=` and you can add end of line comments after a `#` or `!` character. Lines starting with `*` in column 1 are treated as comment lines.

5.11.6 Hints on Good Model Formulation

This section will contain some comments on how to formulate a nonlinear model so it becomes easier to solve with CONOPT. Most of the recommendations will be useful for any nonlinear solver, but not all. We will try to mention when a recommendation is CONOPT specific.

5.11.6.1 Initial Values

Good initial values are important for many reasons. Initial values that satisfy or closely satisfy many of the constraints reduces the work involved in finding a first feasible solution. Initial values that in addition are close to the optimal ones also reduce the distance to the final point and therefore indirectly the computational effort. The progress of the optimization algorithm is based on good directional information and therefore on good derivatives. The derivatives in a nonlinear model depend on the current point, and the initial point in which the initial derivatives are computed is therefore again important. Finally, non-convex models may have multiple solutions, but the modeler is looking for one in a particular part of the search space; an initial point in the right neighborhood is more likely to return the desired solution.

The initial values used by CONOPT are all coming from GAMS. The initial values used by GAMS are by default the value zero projected on the bounds. I.e. if a variable is free or has a lower bound of zero, then its default initial value is zero. Unfortunately, zero is in many cases a bad initial value for a nonlinear variable. An initial value of zero is especially bad if the variable appears in a product term since the initial derivative becomes zero, and it appears as if the function does not depend on the variable. CONOPT will

warn you and ask you to supply better initial values if the number of derivatives equal to zero is larger than 20 percent.

If a variable has a small positive lower bound, for example because it appears as an argument to the Log function or as a denominator, then the default initial value is this small lower bound and it is also bad since this point will have very large first and second derivatives.

You should therefore supply as many sensible initial values as possible by making assignment to the level value, var.L, in GAMS. An easy possibility is to initialize all variables to 1, or to the scale factor if you use GAMS' scaling option. A better possibility is to select reasonable values for some variables that from the context are known to be important, and then use some of the equations of the model to derive values for other variables. A model may contain the following equation:

```
pmDef(it) .. pm(it) =e= pwm(it)*er*(1 + tm(it)) ;
```

where pm, pwm, and er are variables and tm is a parameter. The following assignment statements use the equation to derive consistent initial values for PM from sensible initial values for pwm and er:

```
er.l = 1; pwm.l(it) = 1;
pm.l(it) = pwm.l(it)*er.l*(1 + tm(it)) ;
```

With these assignments equation pmDef will be feasible in the initial point, and since CONOPT uses a feasible path method it will remain feasible throughout the optimization (unless the pre-processor destroys it, see section [Iteration 1: Preprocessing](#) in [Appendix A](#)).

If CONOPT has difficulties finding a feasible solution for your model you should try to use this technique to create an initial point in which as many equations as possible are satisfied. You may also try the optional Crash procedure described in section [Preprocessing: The Optional Crash Procedure](#) in [Appendix A](#) by adding the line `lstcrs=t` to the CONOPT options file. The crash procedure tries to identify equations with a mixture of uninitialized variables and variables with initial values, and it solves the equations with respect to the uninitialized variables; the effect is similar to the manual procedure shown above.

5.11.6.2 Bounds

Bounds have two purposes in nonlinear models. Some bounds represent constraints on the reality that is being modeled, e.g. a variable must be positive. These bounds are called model bounds. Other bounds help the algorithm by preventing it from moving far away from any optimal solution and into regions with singularities in the nonlinear functions or unreasonably large function or derivative values. These bounds are called algorithmic bounds.

Model bounds have natural roots and do not cause any problems. Algorithmic bounds require a closer look at the functional form of the model. The content of a Log should be greater than say 1.e-3, the content of an Exp should be less than 5 to 8, and a denominator should be greater than say 1.e-2. These recommended lower bounds of 1.e-3 and 1.e-2 may appear to be unreasonably large. However, both $\text{Log}(x)$ and $1/x$ are extremely nonlinear for small arguments. The first and second derivatives of $\text{Log}(x)$ at $x=1.e-3$ are 1.e+3 and -1.e6, respectively, and the first and second derivatives of $1/x$ at $x=1.e-2$ are -1.e+4 and 2.e+6, respectively.

If the content of a Log or Exp function or a denominator is an expression then it may be advantageous to introduce a bounded intermediate variable as discussed in the next section.

Note that bounds in some cases can slow the solution process down. Too many bounds may for example introduce degeneracy. If you have constraints of the following type

```
vub(i) .. x(i) =l= y;
```

or

```
ysum .. y =e= sum( i, x(i) );
```

and x is a **Positive Variable** then you should in general not declare y a **Positive Variable** or add a lower bound of zero on y . If y appears in a nonlinear function you may need a strictly positive bound. Otherwise, you should declare y a free variable; CONOPT will then make y basic in the initial point and y will remain basic throughout the optimization. New logic in CONOPT tries to remove this problem by detecting when a harmful bound is redundant so it can be removed, but it is not yet a fool proof procedure.

Section [Iteration 1: Preprocessing](#) in [Appendix A](#) gives another example of bounds that can be counter productive.

5.11.6.3 Simple Expressions

The following model component

```
Parameter mu(i);
Variable x(i), s(i), obj;
Equation objDef;
objDef .. obj =e= Exp( Sum( i, Sqr( x(i) - mu(i) ) / s(i) ) );
```

can be re-written in the slightly longer but simpler form

```
Parameter mu(i);
Variable x(i), s(i), obj, inTerm;
Equation intDef, objDef;
intDef .. inTerm =e= Sum( i, Sqr( x(i) - mu(i) ) / s(i) );
objDef .. obj =e= Exp( inTerm );
```

The first formulation has very complex derivatives because Exp is taken of a long expression. The second formulation has much simpler derivatives; Exp is taken of a single variable, and the variables in intDef appear in a sum of simple independent terms.

In general, try to avoid nonlinear functions of expressions, divisions by expressions, and products of expressions, especially if the expressions depend on many variables. Define intermediate variables that are equal to the expressions and apply the nonlinear function, division, or product to the intermediate variable. The model will become larger, but the increased size is taken care of by CONOPT's sparse matrix routines, and it is compensated by the reduced complexity. If the model is solved with CONOPT using explicit second derivatives then simple expressions will result in sparser second derivatives that are both faster to compute and to use.

The reduction in complexity can be significant if an intermediate expression is linear. The following model fragment:

```
Variable x(i), y;
Equation yDef;
yDef .. y =e= 1 / Sum(i, x(i) );
```

should be written as

```
Variable x(i), xSum, y;
Equation xSumDef, yDef;
xSumDef .. xSum =e= Sum(i, x(i) );
yDef     .. y =e= 1 / xSum;
xSum.lo = 1.e-2;
```

for three reasons. First, because the number of nonlinear derivatives is reduced in number and complexity. Second, because the lower bound on the intermediate result will bound the search away from the singularity at $xSum = 0$. And third, because the matrix of second derivatives for the last model only depend on $xSum$ while it depends on all x in the first model.

The last example shows an added potential saving by expanding functions of linear expressions. A constraint depends in a nonlinear fashion on the accumulated investments, inv , like

```
con(i) .. f( Sum( j$(ord(j) le ord(i)), inv(j) ) ) =l= b(i);
```

A new intermediate variable, $cap(i)$, that is equal to the content of the Sum can be defined recursively with the constraints

```
cDef(i) .. cap(i) =e= inv(i) + cap(i-1);
```

and the original constraints become

```
con(i) .. f( cap(i) ) =l= b(i);
```

The reformulated model has n additional variables and n additional linear constraints. In return, the original n complex nonlinear constraints have been changed into n simpler nonlinear constraints. And the number of Jacobian elements, that has a direct influence on much of the computational work both in GAMS and in CONOPT, has been reduced from $n*(n+1)/2$ nonlinear elements to $3*n-1$ linear elements and only n nonlinear element. If f is an invertible increasing function you may even rewrite the last constraint as a simple bound:

```
cap.lo(i) = finv(b(i));
```

Some NLP solvers encourage you to move as many nonlinearities as possible into the objective which may make the objective very complex. This is neither recommended nor necessary with CONOPT. A special pre-processing step (discussed in section [Iteration 1: Preprocessing](#) in [Appendix A](#)) will aggregate parts of the model if it is useful for CONOPT without increasing the complexity in GAMS.

5.11.6.4 Scaling

Nonlinear as well as Linear Programming Algorithms use the derivatives of the objective function and the constraints to determine good search directions, and they use function values to determine if constraints are satisfied or not. The scaling of the variables and constraints, i.e. the units of measurement used for the variables and constraints, determine the relative size of the derivatives and of the function values and thereby also the search path taken by the algorithm.

Assume for example that two goods of equal importance both cost \$1 per kg. The first is measured in gram, the second in tons. The coefficients in the cost function will be \$1000/g and \$0.001/ton, respectively. If cost is measured in \$1000 units then the coefficients will be 1 and 1.e-6, and the smaller may be ignored by the algorithm since it is comparable to some of the zero tolerances.

CONOPT assumes implicitly that the model to be solved is well scaled. In this context well scaled means:

- Basic and superbasic solution values are expected to be around 1, e.g. from 0.01 to 100. Nonbasic variables will be at a bound, and the bound values should not be larger than say 100.
- Dual variables (or marginals) on active constraints are expected to be around 1, e.g. from 0.01 to 100. Dual variables on non-binding constraints will of course be zero.
- Derivatives (or Jacobian elements) are expected to be around 1, e.g. from 0.01 to 100.

Variables become well scaled if they are measured in appropriate units. In most cases you should select the unit of measurement for the variables so their expected value is around unity. Of course there will always be some variation. Assume $x(i)$ is the production at location i . In most cases you should select the same unit of measurement for all components of x , for example a value around the average capacity.

Equations become well scaled if the individual terms are measured in appropriate units. After you have selected units for the variables you should select the unit of measurement for the equations so the expected values of the individual terms are around one. If you follow these rules, material balance equations will usually have coefficients of plus and minus one.

Derivatives will usually be well scaled whenever the variables and equations are well scaled. To see if the derivatives are well scaled, run your model with a positive Option LimRow and look for very large or very small coefficients in the equation listing in the GAMS output file.

CONOPT computes a measure of the scaling of the Jacobian, both in the initial and in the final point, and if it seems large it will be printed. The message looks like:

```
** WARNING **  The variance of the derivatives in the initial
                  point is large (= 4.1 ). A better initial
                  point, a better scaling, or better bounds on the
                  variables will probably help the optimization.
```

The variance is computed as $\text{Sqrt}(\text{Sum}(\text{Log}(\text{Abs}(\text{jac}(i)))^2)/\text{nz})$ where $\text{jac}(i)$ represents the nz nonzero derivatives (Jacobian elements) in the model. A variance of 4.1 corresponds to an average value of $\text{Log}(\text{jac})^2$ of 4.1^2 , which means that Jacobian values outside the range $\text{Exp}(-4.1)=0.017$ to $\text{Exp}(+4.1)=60.4$ are about as common as values inside. This range is for most models acceptable, while a variance of 5, corresponding to about half the derivatives outside the range $\text{Exp}(-5)=0.0067$ to $\text{Exp}(+5)=148$, can be dangerous.

5.11.6.4.1 Scaling of Intermediate Variables Many models have a set of variables with a real economic or physical interpretation plus a set of intermediate or helping variables that are used to simplify the model. We have seen some of these in section [Simple Expressions](#) on Simple Expressions. It is usually rather easy to select good scaling units for the real variables since we know their order of magnitude from economic or physical considerations. However, the intermediate variables and their defining equations should preferably also be well scaled, even if they do not have an immediate interpretation. Consider the following model fragment where x, y, and z are variables and y is the intermediate variable:

```
Set p / p0*p4 /
Parameter a(p) / p0 211, p1 103, p2 42, p3 31, p4 6 /
yDef .. y =e= Sum(p, a(p)*Power(x,Ord(p)-1));
zDef .. z =e= Log(y);
```

x lies in the interval 1 to 10 which means that y will be between 211 and 96441 and Z will be between 5.35 and 11.47. Both x and z are reasonably scaled while y and the terms and derivatives in yDef are about a factor 1.e4 too large. Scaling y by 1.e4 and renaming it ys gives the following scaled version of the model fragment:

```
yDefs1 .. ys =e= Sum(p, a(p)*Power(x,Ord(p)-1))*1.e-4;
zDefs1 .. z =e= Log(ys*1.e4);
```

The z equation can also be written as

```
zDefs2 .. z =e= Log(ys) + Log(1.e4);
```

Note that the scale factor 1.e-4 in the yDefs1 equation has been placed on the right hand side. The mathematically equivalent equation

```
yDefs2 .. ys*1.e4 =e= Sum(p, a(p)*Power(x,Ord(p)-1));
```

will give a well scaled YS, but the right hand side terms of the equation and their derivatives have not changed from the original equation yDef and they are still far too large.

5.11.6.4.2 Using the Scale Option in GAMS The rules for good scaling mentioned above are exclusively based on algorithmic needs. GAMS has been developed to improve the effectiveness of modelers, and one of the best ways seems to be to encourage modelers to write their models using a notation that is as "natural" as possible. The units of measurement is one part of this natural notation, and there is unfortunately often a conflict between what the modeler thinks is a good unit and what constitutes a well scaled model.

To facilitate the translation between a natural model and a well scaled model GAMS has introduced the concept of a scale factor, both for variables and equations. The notation and the definitions are quite simple. First of all, scaling is by default turned off. To turn it on, enter the statement `<model>.ScaleOpt = 1;` in your GAMS program somewhere after the `Model` statement and before the `Solve` statement. `<model>` is the name of the model to be solved. If you want to turn scaling off again, enter the statement `<model>.ScaleOpt = 0;` somewhere before the next `Solve`.

The scale factor of a variable or an equation is referenced with the suffix ".Scale", i.e. the scale factor of variable x(i) is referenced as x.Scale(i). Note that there is one scale value for each individual component of a multidimensional variable or equation. Scale factors can be defined in assignment statements with x.Scale(i) on the left hand side, and scale factors, both from variables and equations, can be used on the right hand side, for example to define other scale factors. The default scale factor is always 1, and a scale factor must be positive; GAMS will generate an execution time error if the scale factor is less than 1.e-20.

The mathematical definition of scale factors is as follows: The scale factor on a variable, V^s is used to related the variable as seen by the modeler, V^m , to the variable as seen by the algorithm, V^a , as follows:

$$V^m = V^a * V^s$$

This means, that if the variable scale, V^s , is chosen to represent the order of magnitude of the modeler's variable, V^m , then the variable seen by the algorithm, V^a , will be around 1. The scale factor on an equation, G^s , is used to related the equation as seen by the modeler, G^m , to the equation as seen by the algorithm, G^a , as follows:

$$G^m = G^a * G^s$$

This means, that if the equation scale, G^s , is chosen to represent the order of magnitude of the individual terms in the modelers version of the equation, G^m , then the terms seen by the algorithm, G^a , will be around 1.

The derivatives in the scaled model seen by the algorithm, i.e. dG^a/dV^a , are related to the derivatives in the modelers model, dG^m/dV^m , through the formula:

$$dG^a/dV^a = dG^m/dV^m * V^s/G^s$$

i.e. the modelers derivative is multiplied by the scale factor of the variable and divided by the scale factor of the equation. Note, that the derivative is unchanged if $V^s = G^s$. Therefore, if you have a GAMS equation like

```
G .. V =e= expression;
```

and you select $G^s = V^s$ then the derivative of V will remain 1. If we apply these rules to the example above with an intermediate variable we can get the following automatic scale calculation, based on an "average" reference value for x :

```
Scalar xRef; xRef = 6;
y.Scale = Sum(p, a(p)*Power(xRef,Ord(p)-1));
yDef.Scale = y.Scale;
```

or we could scale y using values at the end of the x interval and add safeguards as follows:

```
y.Scale = Max( Abs(Sum(p, a(p)*Power(x.Lo,Ord(p)-1))),
               Abs(Sum(p, a(p)*Power(x.Up,Ord(p)-1))),
               0.01 );
```

Lower and upper bounds on variables are automatically scaled in the same way as the variable itself. Integer and binary variables cannot be scaled.

GAMS' scaling is in most respects hidden for the modeler. The solution values reported back from a solution algorithm, both primal and dual, are always reported in the user's notation. The algorithm's versions of the equations and variables are only reflected in the derivatives in the equation and column listings in the GAMS output if **Option LimRow** and/or **LimCol** are positive, and in debugging output from the solution algorithm, generated with **Option SysOut = On**. In addition, the numbers in the algorithms iteration log will represent the scaled model: the infeasibilities and reduced gradients will correspond to the scaled model, and if the objective variable is scaled, the value of the objective function will be the scaled value.

A final warning about scaling of multidimensional variables is appropriate. Assume variable $x(i,j,k)$ only appears in the model when the parameter $ijk(i,j,k)$ is nonzero, and assume that $\text{Card}(i) = \text{Card}(j) = \text{Card}(k) = 100$ while $\text{Card}(ijk)$ is much smaller than $100*2 = 1.e6$. Then you should only scale the variables that appear in the model, i.e.

```
x.Scale(i,j,k)$ijk(i,j,k) = expression;
```

The statement

```
x.Scale(i,j,k) = expression;
```

will generate records for x in the GAMS database for all combinations of i , j , and k for which the expression is different from 1, i.e. up to 1.e6 records, and apart from spending a lot of time you will very likely run out of memory. Note that this warning also applies to non-default lower and upper bounds.

5.11.7 NLP and DNLP Models

GAMS has two classes of nonlinear model, NLP and DNLP. NLP models are defined as models in which all functions that appear with endogenous arguments, i.e. arguments that depend on model variables, are smooth with smooth derivatives. DNLP models can in addition use functions that are smooth but have discontinuous derivatives. The usual arithmetic operators (+, -, *, /, and **) can appear on both model classes.

The functions that can be used with endogenous arguments in a DNLP model and not in an NLP model are Abs, Min, and Max and as a consequence the indexed operators SMin and SMax.

Note that the offending functions can be applied to expressions that only involve constants such as parameters, var.l, and equ.m. Fixed variables are in principle constants, but GAMS makes its tests based on the functional form of a model, ignoring numerical parameter values and numerical bound values, and terms involving fixed variables can therefore not be used with Abs, Min, or Max in an NLP model.

The NLP solvers used by GAMS can also be applied to DNLP models. However, it is important to know that the NLP solvers attempt to solve the DNLP model as if it was an NLP model. The solver uses the derivatives of the constraints with respect to the variables to guide the search, and it ignores the fact that some of the derivatives may change discontinuously. There are at the moment no GAMS solvers designed specifically for DNLP models and no solvers that take into account the discontinuous nature of the derivatives in a DNLP model.

5.11.7.1 DNLP Models: What Can Go Wrong?

Solvers for NLP Models are all based on making marginal improvements to some initial solution until some optimality conditions ensure no direction with marginal improvements exist. A point with no marginally improving direction is called a Local Optimum.

The theory about marginal improvements is based on the assumption that the derivatives of the constraints with respect to the variables are a good approximations to the marginal changes in some neighborhood around the current point.

Consider the simple NLP model, Min Sqr(x), where x is a free variable. The marginal change in the objective is the derivative of Sqr(x) with respect to x, which is 2*x. At x = 0, the marginal change in all directions is zero and x = 0 is therefore a Local Optimum.

Next consider the simple DNLP model, Min Abs(x), where x again is a free variable. The marginal change in the objective is still the derivative, which is +1 if x > 0 and -1 if x < 0. When x = 0, the derivative depends on whether we are going to increase or decrease x. Internally in the DNLP solver, we cannot be sure whether the derivative at 0 will be -1 or +1; it can depend on rounding tolerances. An NLP solver will start in some initial point, say x = 1, and look at the derivative, here +1. Since the derivative is positive, x is reduced to reduce the objective. After some iterations, x will be zero or very close to zero. The derivative will be +1 or -1, so the solver will try to change x. however, even small changes will not lead to a better objective function. The point x = 0 does not look like a Local Optimum, even though it is a Local Optimum. The result is that the NLP solver will muddle around for some time and then stop with a message saying something like: "The solution cannot be improved, but it does not appear to be optimal."

In this first case we got the optimal solution so we can just ignore the message. However, consider the following simple two-dimensional DNLP model: Min Abs(x1+x2) + 5*Abs(x1-x2) with x1 and x2 free variables. Start the optimization from x1 = x2 = 1. Small increases in x1 will increase both terms and small decreases in x1 (by dx) will decrease the first term by dx but it will increase the second term by 5*dx. Any change in x1 only is therefore bad, and it is easy to see that any change in x2 only also is bad. An NLP solver may therefore be stuck in the point x1 = x2 = 1, even though it is not a local solution: the direction (dx1,dx2) = (-1,-1) will lead to the optimum in x1 = x2 = 0. However, the NLP solver cannot distinguish what happens with this model from what happened in the previous model; the message will be of the same type: "The solution cannot be improved, but it does not appear to be optimal."

5.11.7.2 Reformulation from DNLP to NLP

The only reliable way to solve a DNLP model is to reformulate it as an equivalent smooth NLP model. Unfortunately, it may not always be possible. In this section we will give some examples of reformulations.

The standard reformulation approach for the ABS function is to introduce positive and negative deviations as extra variables: The term $z = \text{Abs}(f(x))$ is replaced by $z = fPlus + fMinus$, $fPlus$ and $fMinus$ are declared as positive variables and they are defined with the identity: $f(x) = fPlus - fMinus$. The discontinuous derivative from the Abs function has disappeared and the part of the model shown here is smooth. The discontinuity has been converted into lower bounds on the new variables, but bounds are handled routinely by any NLP solver. The feasible space is larger than before; $f(x) = 5$ can be obtained both with $fPlus = 5$, $fMinus = 0$, and $z = 5$, and with $fPlus = 1000$, $fMinus = 995$, and $z = 1995$. Provided the objective function has some term that tries to minimize z , either $fPlus$ or $fMinus$ will become zero and z will end with its proper value.

You may think that adding the smooth constraint $fPlus * fMinus = 0$ would ensure that either $fPlus$ or $fMinus$ is zero. However, this type of so-called complementarity constraint is "bad" in any NLP model. The feasible space consists of the two half lines: ($fPlus = 0$ and $fMinus \geq 0$) and ($fPlus \geq 0$ and $fMinus = 0$). Unfortunately, the marginal change methods used by most NLP solvers cannot move from one half line to the other, and the solution is stuck at the half line it happens to reach first.

There is also a standard reformulation approach for the Max function. The equation $z = \text{Max}(f(x), g(y))$ is replaced by the two inequalities, $z \geq f(x)$ and $z \geq g(y)$. Provided the objective function has some term that tries to minimize z , one of the constraints will become binding as equality and z will indeed be the maximum of the two terms.

The reformulation for the Min function is similar. The equation $z = \text{Min}(f(x), g(y))$ is replaced by the two inequalities, $z \leq f(x)$ and $z \leq g(y)$. Provided the objective function has some term that tries to maximize z , one of the constraints will become binding as equality and z is indeed the minimum of the two terms.

Max and Min can have more than two arguments and the extension should be obvious.

The non-smooth indexed operators, SMax and SMin can be handled using a similar technique: for example, $z = \text{SMax}(i, f(x,i))$ is replaced by the indexed inequality: $\text{inEq}(i) \dots z \leq f(x,i)$;

The reformulations that are suggested here all enlarge the feasible space. They require the objective function to move the final solution to the intersection of this larger space with the original feasible space. Unfortunately, the objective function is not always so helpful. If it is not, you may try using one of the smooth approximations described next. However, you should realize, that if the objective function cannot help the "good" approximations described here, then your overall model is definitely non-convex and it is likely to have multiple local optima.

5.11.7.3 Smooth Approximations

Smooth approximations to the non-smooth functions ABS, MAX, and MIN are approximations that have function values close to the original functions, but have smooth derivatives.

A smooth GAMS approximation for $\text{Abs}(f(x))$ is

$$\text{Sqrt}(\text{Sqr}(f(x)) + \text{Sqr}(\text{delta}))$$

where delta is a small scalar. The value of delta can be used to control the accuracy of the approximation and the curvature around $f(x) = 0$. The approximation error is largest when $f(x)$ is zero, in which case the error is delta. The error is reduced to approximately $\text{Sqr}(\text{delta})/2$ for $f(x) = 1$. The second derivative is $1/\text{delta}$ at $f(x) = 0$ (excluding terms related to the second derivative of $f(x)$). A delta value between $1.e-3$ and $1.e-4$ should in most cases be appropriate. It is possible to use a larger value in an initial optimization, reduce it and solve the model again. You should note, that if you reduce delta below $1.e-4$ then large second order terms might lead to slow convergence or even prevent convergence.

The approximation shown above has its largest error when $f(x) = 0$ and smaller errors when $f(x)$ is far from zero. If it is important to get accurate values of Abs exactly when $f(x) = 0$, then you may use the alternative approximation

$$\text{Sqrt}(\text{Sqr}(f(x)) + \text{Sqr}(\text{delta})) - \text{delta}$$

instead. The only difference is the constant term. The error is zero when $f(x)$ is zero and the error grows to -delta when $f(x)$ is far from zero.

Some theoretical work uses the Huber, $H(*)$, function as an approximation for Abs. The Huber function is defined as

$$\begin{aligned} H(x) &= x \text{ for } x > \text{delta}, \\ H(x) &= -x \text{ for } x < -\text{delta} \text{ and} \\ H(x) &= \text{Sqr}(x)/2/\text{delta} + \text{delta}/2 \text{ for } -\text{delta} < x < \text{delta}. \end{aligned}$$

Although the Huber function has some nice properties, it is for example accurate when $\text{Abs}(x) > \text{delta}$, it is not so useful for GAMS work because it is defined with different formula for the three pieces.

A smooth GAMS approximation for $\text{Max}(f(x), g(y))$ is

$$(f(x) + g(y) + \text{Sqrt}(\text{Sqr}(f(x)-g(y)) + \text{Sqr}(\text{delta}))) / 2$$

where delta again is a small scalar. The approximation error is $\text{delta}/2$ when $f(x) = g(y)$ and decreases with the difference between the two terms. As before, you may subtract a constant term to shift the approximation error from the area $f(x) = g(y)$ to areas where the difference is large. The resulting approximation becomes

$$(f(x) + g(y) + \text{Sqrt}(\text{Sqr}(f(x)-g(y)) + \text{Sqr}(\text{delta}))) - \text{delta} / 2$$

Similar smooth GAMS approximations for $\text{Min}(f(x), g(y))$ are

$$(f(x) + g(y) - \text{Sqrt}(\text{Sqr}(f(x)-g(y)) + \text{Sqr}(\text{delta}))) / 2$$

and

$$(f(x) + g(y) - \text{Sqrt}(\text{Sqr}(f(x)-g(y)) + \text{Sqr}(\text{delta}))) + \text{delta} / 2$$

Appropriate delta values are the same as for the Abs approximation: in the range from $1.e-2$ to $1.e-4$.

It appears that there are no simple symmetric extensions for Max and Min of three or more arguments or for indexed SMax and SMin.

5.11.7.4 Are DNLP Models Always Non-smooth?

A DNLP model is defined as a model that has an equation with an Abs, Max, or Min function with endogenous arguments. The non-smooth properties of DNLP models are derived from the non-smooth properties of these functions through the use of the chain rule. However, composite expressions involving Abs, Max, or Min can in some cases have smooth derivatives and the model can therefore in some cases be smooth.

One example of a smooth expression involving an Abs function is common in water systems modeling. The pressure loss over a pipe, dH , is proportional to the flow, Q , to some power, P . P is usually around +2. The sign of the loss depend on the direction of the flow so dH is positive if Q is positive and negative if Q is negative. Although GAMS has a Sign function, it cannot be used in a model because of its discontinuous nature. Instead, the pressure loss can be modeled with the equation $dH = \text{const} * Q * \text{Abs}(Q)^{(P-1)}$, where the sign of the Q -term takes care of the sign of dH , and the Abs function guaranties that the real power $**$ is applied to a non-negative number. Although the expression involves the Abs function, the derivatives are smooth as long as P is greater than 1. The derivative with respect to Q is $\text{const} * (P-1) * \text{Abs}(Q)^{(P-1)}$ for $Q > 0$ and $-\text{const} * (P-1) * \text{Abs}(Q)^{(P-1)}$ for $Q < 0$. The limit for Q going to zero from both right and left is 0, so the derivative is smooth in the critical point $Q = 0$ and the overall model is therefore smooth.

Another example of a smooth expression is the following terribly looking Sigmoid expression:

$$\text{Sigmoid}(x) = \text{Exp}(\text{Min}(x, 0)) / (1 + \text{Exp}(-\text{Abs}(x)))$$

The standard definition of the sigmoid function is

$$\text{Sigmoid}(x) = \text{Exp}(x) / (1 + \text{Exp}(x))$$

This definition is well behaved for negative and small positive x , but it not well behaved for large positive x since Exp overflows. The alternative definition:

$$\text{Sigmoid}(x) = 1 / (1 + \text{Exp}(-x))$$

is well behaved for positive and slightly negative x , but it overflows for very negative x . Ideally, we would like to select the first expression when x is negative and the second when x is positive, i.e.

$$\text{Sigmoid}(x) = (\text{Exp}(x)/(1+\text{Exp}(x)))\$ (x < 0) + (1/(1+\text{Exp}(-x)))\$ (x > 0)$$

but a \$-control that depends on an endogenous variable is illegal. The first expression above solves this problem. When x is negative, the nominator becomes $\text{Exp}(x)$ and the denominator becomes $1+\text{Exp}(x)$. And when x is positive, the nominator becomes $\text{Exp}(0) = 1$ and the denominator becomes $1+\text{Exp}(x)$. Since the two expressions are mathematically identical, the combined expression is of course smooth, and the Exp function is never evaluated for a positive argument.

Unfortunately, GAMS cannot recognize this and similar special cases so you must always solve models with endogenous Abs, Max, or Min as DNLP models, even in the cases where the model is smooth.

5.11.7.5 Are NLP Models Always Smooth?

NLP models are defined as models in which all operators and functions are smooth. The derivatives of composite functions, that can be derived using the chain rule, will therefore in general be smooth. However, it is not always the case. The following simple composite function is not smooth: $y = \text{Sqrt}(\text{Sqr}(x))$. The composite function is equivalent to $y = \text{Abs}(x)$, one of the non-smooth DNLP functions.

What went wrong? The chain rule for computing derivatives of a composite function assumes that all intermediate expressions are well defined. However, the derivative of Sqrt grows without bound when the argument approaches zero, violating the assumption.

There are not many cases that can lead to non-smooth composite functions, and they are all related to the case above: The real power, $x**y$, for $0 < y < 1$ and x approaching zero. The Sqrt function is a special case since it is equivalent to $x**y$ for $y = 0.5$.

If you have expressions involving a real power with an exponent between 0 and 1 or a Sqrt , you should in most cases add bounds to your variables to ensure that the derivative or any intermediate terms used in their calculation become undefined. In the example above, $\text{Sqrt}(\text{Sqr}(x))$, a bound on x is not possible since x should be allowed to be both positive and negative. Instead, changing the expression to $\text{Sqrt}(\text{Sqr}(x) + \text{Sqr}(\text{delta}))$ may lead to an appropriate smooth formulation.

Again, GAMS cannot recognize the potential danger in an expression involving a real power, and the presence of a real power operator is not considered enough to flag a model as a DNLP model. During the solution process, the NLP solver will compute constraint values and derivatives in various points within the bounds defined by the modeler. If these calculations result in undefined intermediate or final values, a function evaluation error is reported, an error counter is incremented, and the point is flagged as a bad point. The following action will then depend on the solver. The solver may try to continue, but only if the modeler has allowed it with an `Option DomLim = xxx;`. The problem of detecting discontinuities is changed from a structural test at the GAMS model generation stage to a dynamic test during the solution process.

You may have a perfectly nice model in which intermediate terms become undefined. The composite function $\text{Sqrt}(\text{Power}(x,3))$ is mathematically well defined around $x = 0$, but the computation will involve the derivative of Sqrt at zero, that is undefined. It is the modeler's responsibility to write expressions in a way that avoids undefined intermediate terms in the function and derivatives computations. In this case, you may either add a small strictly positive lower bound on x or rewrite the function as $x**1.5$.

5.11.8 APPENDIX A: Algorithmic Information

The objective of this Appendix is to give technically oriented users some understanding of what CONOPT is doing so they can get more information out of the iteration log. This information can be used to prevent or circumvent algorithmic difficulties or to make informed guesses about which options to experiment with to improve CONOPT's performance on particular model classes.

5.11.8.1 Overview of GAMS/CONOPT

GAMS/CONOPT is a GRG-based algorithm specifically designed for large nonlinear programming problems expressed in the following form

<code>min or max</code>	$f(x)$	(1)
<code>subject to</code>	$g(x) = b$	(2)
<code>lo < x < up</code>		(3)

where x is the vector of optimization variables, lo and up are vectors of lower and upper bounds, some of which may be minus or plus infinity, b is a vector of right hand sides, and f and g are differentiable nonlinear functions that define the model. n will in the following denote the number of variables and m the number of equations. (2) will be referred to as the (general) constraints and (3) as the bounds.

The relationship between the mathematical model in (1)-(3) above and the GAMS model is simple: The inequalities defined in GAMS with $=1=$ or $=g=$ are converted into equalities by addition of properly bounded slacks. Slacks with lower and upper bound of zero are added to all GAMS equalities to ensure that the Jacobian matrix, i.e. the matrix of derivatives of the functions g with respect to the variables x , has full row rank. All these slacks are together with the normal GAMS variables included in x . lo represent the lower bounds defined in GAMS, either implicitly with the Positive Variable declaration, or explicitly with the Var.Lo notation, as well as any bounds on the slacks. Similarly, up represent upper bounds defined in GAMS, e.g. with the Var.Up notation, as well as any bounds on the slacks. g represent the non-constant terms of the GAMS equations themselves; non-constant terms appearing on the right hand side are by GAMS moved to the left hand side and constant terms on the left hand side are moved to the right. The objective function f is simply the GAMS variable to be minimized or maximized.

Additional comments on assumptions and design criteria can be found in the Introduction to the main text.

5.11.8.2 The CONOPT Algorithm

The algorithm used in GAMS/CONOPT is based on the GRG algorithm first suggested by Abadie and Carpentier (1969). The actual implementation has many modifications to make it efficient for large models and for models written in the GAMS language. Details on the algorithm can be found in Drud (1985 and 1992). Here we will just give a short verbal description of the major steps in a generic GRG algorithm. The later sections in this Appendix will discuss some of the enhancements in CONOPT that make it possible to solve large models.

The key steps in any GRG algorithm are:

1. Initialize and Find a feasible solution.
 2. Compute the Jacobian of the constraints, J .
 3. Select a set of n basic variables, x_b , such that B , the sub- matrix of basic column from J , is nonsingular. Factorize B . The remaining variables, x_n , are called nonbasic.
 4. Solve $B^T u = df/dx_b$ for the multipliers u .
 5. Compute the reduced gradient, $r = df/dx - J^T u$. r will by definition be zero for the basic variables.
 6. If r projected on the bounds is small, then stop. The current point is close to optimal.
 7. Select the set of superbasic variables, x_s , as a subset of the nonbasic variables that profitably can be changed, and find a search direction, d_s , for the superbasic variables based on r_s and possibly on some second order information.
 8. Perform a line search along the direction d . For each step, x_s is changed in the direction d_s and x_b is subsequently adjusted to satisfy $g(x_b, x_s) = b$ in a pseudo-Newton process using the factored B from step 3.
 9. Go to 2.
-

The individual steps are of course much more detailed in a practical implementation like CONOPT. Step 1 consists of several pre-processing steps as well as a special Phase 0 and a scaling procedure as described in the following sections [Iteration 0: The Initial Point](#) to [Finding a Feasible Solution: Phase 0](#). The optimizing steps are specialized in several versions according to the whether the model appears to be almost linear or not. For "almost" linear models some of the linear algebra work involving the matrices J and B can be avoided or done using cheap LP-type updating techniques, second order information is not relevant in step 7, and the line search in step 8 can be improved by observing that the optimal step as in LP almost always will be determined by the first variable that reaches a bound. Similarly, when the model appears to be fairly nonlinear other aspects can be optimized: the set of basic variables will often remain constant over several iterations, and other parts of the sparse matrix algebra will take advantage of this (section [Finding a Feasible Solution: Phase 1 and 2](#) and [Linear and Nonlinear Mode: Phase 1 to 4](#)). If the model is "very" linear an improved search direction (step 7) can be computed using specialized inner LP-like iterations (section [Linear Mode: The SLP Procedure](#)) and a steepest edge procedure can be useful for certain models that needs very many iterations (section [Linear Mode: The Steepest Edge Procedure](#)). If the model is "very" nonlinear and has many degrees of freedom an improved search direction (step 7) can be computed using specialized inner SQP-like iterations based on exact second derivatives for the model (section [Nonlinear Mode: The SQP Procedure](#)).

The remaining two sections give some short guidelines for selecting non-default options (section [How to Select Non-default Options](#)), and discuss miscellaneous topics (section [Miscellaneous Topics](#)) such as CONOPT's facilities for strictly triangular models (section [Triangular Models](#)) and for square systems of equations, in GAMS represented by the model class called CNS or Constrained Nonlinear System (section [Constrained Nonlinear System or Square Systems of Equations](#)), as well as numerical difficulties due to loss of feasibility (section [Loss of Feasibility](#)) and slow or no progress due to stalling (section [Stalling](#)).

5.11.8.3 Iteration 0: The Initial Point

The first few "iterations" in the iteration log (See section [Iteration Output](#)), in the main text for an example) are special initialization iterations, but they have been counted as real iterations to allow the user to interrupt at various stages during initialization. Iteration 0 corresponds to the input point exactly as it was received from GAMS. The sum of infeasibilities in the column labeled "Infeasibility" includes all residuals, also from the objective constraint where "z =e= expression" will give rise to the term $\text{Abs}(z - \text{expression})$ that may be nonzero if z has not been initialized. You may stop CONOPT after iteration 0 with `Option IterLim = 0;` in GAMS. The solution returned to GAMS will contain the input point and the values of the constraints in this point. The marginals of both variables and equations have not yet been computed and they will be returned as EPS.

This possibility can be used for debugging when you have a reference point that should be feasible, but is infeasible for unknown reasons. Initialize all variables to their reference values, also all intermediate variables, and call CONOPT with `IterLim = 0`. Then compute and display the following measures of infeasibility for each block of constraints, represented by the generic name `eq`:

```
=e= constraints: Round(Abs(eq.L - eq.Lo),3)
=l= constraints: Round(Min(0,eq.L - eq.Up),3)
=g= constraints: Round(Min(0,eq.Lo - eq.L),3)
```

The Round function rounds to 3 decimal places so GAMS will only display the infeasibilities that are larger than 5×10^{-4} .

Similar information can be derived from inspection of the equation listing generated by GAMS with `Option LimRow = nn;`, but although the method of going via CONOPT requires a little more work during implementation it can be convenient in many cases, for example for large models and for automated model checking.

5.11.8.4 Iteration 1: Preprocessing

Iteration 1 corresponds to a pre-processing step. Constraint-variable pairs that can be solved a priori (so-called pre-triangular equations and variables) are solved and the corresponding variables are assigned their final values. Constraints that always can be made feasible because they contain a free variable with a constant coefficient (so-called post-triangular equation-variable pairs) are excluded from the search for a feasible solution and from the Infeasibility measure in the iteration log. Implicitly, equations and variables are ordered as shown in [Figure 1](#).

5.11.8.4.1 Preprocessing: Pre-triangular Variables and Constraints The pre-triangular equations are those labeled A in [Figure 1](#). They are solved one by one along the "diagonal" with respect to the pre-triangular variables labeled I. In practice, GAMS/CONOPT looks for equations with only one non-fixed variable. If such an equation exists, GAMS/CONOPT tries to solve it with respect to this non-fixed variable. If this is not possible the overall model is infeasible, and the exact reason for the infeasibility is easy to identify as shown in the examples below. Otherwise, the final value of the variable has been determined, the variable can for the rest of the optimization be considered fixed, and the equation can be removed from further consideration. The result is that the model has one equation and one non-fixed variable less. As variables are fixed new equations with only one non-fixed variable may emerge, and CONOPT repeats the process until no more equations with one non-fixed variable can be found.

This pre-processing step will often reduce the effective size of the model to be solved. Although the pre-triangular variables and equations are removed from the model during the optimization, CONOPT keeps them around until the final solution is found. The dual variables for the pre-triangular equations are then computed so they become available in GAMS.

CONOPT has a special option for analyzing and solving completely triangular models. This option is described in section [Triangular Models](#).

The following small GAMS model shows an example of a model with pre-triangular variables and equations:

```
Variable x1, x2, x3, obj;
Equation e1, e2, e3;
e1 .. Log(x1) + x2 =e= 1.6;
e2 .. 5 * x2 =e= 3;
e3 .. obj =e= Sqr(x1) + 2 * Sqr(x2) + 3 * Sqr(x3);
x1.Lo = 0.1;
Model demo / All /; Solve demo using NLP Minimizing obj;
```

Equation e2 is first solved with respect to x2 (result $3/5 = 0.6$). It is easy to solve the equation since x2 appears linearly, and the result will be unique. x2 is then fixed and the equation is removed. Equation e1 is now a candidate since x1 is the only remaining non-fixed variable in the equation. Here x1 appears nonlinear and the value of x1 is found using an iterative scheme based on Newton's method. The iterations are started from the value provided by the modeler or from the default initial value. In this case x1 is started from the default initial value, i.e. the lower bound of 0.1, and the result after some iterations is $x1 = 2.718 = \text{Exp}(1)$.

During the recursive solution process it may not be possible to solve one of the equations. If the lower bound on x1 in the model above is changed to 3.0 you will get the following output:

```
** An equation in the pre-triangular part of the model cannot
   be solved because the critical variable is at a bound.
```

```
Residual=          9.86122887E-02
Tolerance (RTNWTR)= 6.34931126E-07
```

```
e1: Infeasibility in pre-triangular part of model.
x1: Infeasibility in pre-triangular part of model.
```

```
The solution order of the critical equations and
variables is:
```

```
e2 is solved with respect to
x2. Solution value = 6.0000000000E-01
```

```
e1 could not be solved with respect to
x1. Final solution value = 3.0000000000E+00
e1 remains infeasible with residual = 9.8612288668E-02
```

The problem is as indicated that the variable to be solved for is at a bound, and the value suggested by Newton's method is on the infeasible side of the bound. The critical variable is x1 and the critical equation is e1, i.e. x1 tries to exceed its bound when CONOPT solves equation e1 with respect to x1. To help you analyze the problem, especially for larger models, CONOPT reports the solution sequence that led to the infeasibility: In this case equation e2 was first solved with respect to variable x2, then equation e1 was attempted to be solved with respect to x1 at which stage the problem appeared. To make the analysis easier CONOPT will always report the minimal set of equations and variables that caused the infeasibility.

Another type of infeasibility is shown by the following model:

```
Variable x1, x2, x3, obj;
Equation e1, e2, e3;
e1 .. Sqr(x1) + x2 =e= 1.6;
e2 .. 5 * x2 =e= 3;
e3 .. obj =e= Sqr(x1) + 2 * Sqr(x2) + 3 * Sqr(x3);
Model demo / All /; Solve demo using NLP Minimizing obj;
```

where Log(x1) has been replaced by Sqr(x1) and the lower bound on x1 has been removed. This model gives the message:

```
** An equation in the pre-triangular part of the model cannot
   be solved because of too small pivot.
   Adding a bound or initial value may help.
```

```
Residual=          4.0000000
```

Tolerance (RTNWTR)= 6.34931126E-07

e1: Infeasibility in pre-triangular part of model.

x1: Infeasibility in pre-triangular part of model.

The solution order of the critical equations and variables is:

e2 is solved with respect to

x2. Solution value = 6.0000000000E-01

e1 could not be solved with respect to

x1. Final solution value = 0.0000000000E+00

e1 remains infeasible with residual =-4.0000000000E+00

After equation e2 has been solved with respect to x2, equation e1 that contains the term $\text{Sqr}(x)$ should be solved with respect to x1. The initial value of x1 is the default value zero. The derivative of e1 with respect to x1 is therefore zero, and it is not possible for CONOPT to determine whether to increase or decrease x1. If x1 is given a nonzero initial value the model will solve. If x1 is given a positive initial value the equation will give $x1 = 1$, and if x1 is given a negative initial value the equation will give $x1 = -1$. The last type of infeasibility that can be detected during the solution of the pre-triangular or recursive equations is shown by the following example

```
Variable x1, x2, x3, obj;
Equation e1, e2, e3;
e1 .. Log(x1) + x2 =e= 1.6;
e2 .. 5 * x2 =e= 3;
e3 .. obj =e= Sqr(x1) + 2 * Sqr(x2) + 3 * Sqr(x3);
e4 .. x1 + x2 =e= 3.318;
x1.Lo = 0.1;
Model demo / All /; Solve demo using NLP Minimizing obj;
```

that is derived from the first model by the addition of equation e4. This model produces the following output

```
** An equation is inconsistent with other equations in the
pre-triangular part of the model.
```

Residual= 2.81828458E-04

Tolerance (RTNWTR)= 6.34931126E-07

The pre-triangular feasibility tolerance may be relaxed with a line:

```
SET RTNWTR X.XX
```

in the CONOPT control program.

e4: Inconsistency in pre-triangular part of model.

The solution order of the critical equations and variables is:

e2 is solved with respect to

```

x2. Solution value = 6.0000000000E-01

e1 is solved with respect to
x1. Solution value = 2.7182818285E+00

All variables in equation e4 are now fixed
and the equation is infeasible. Residual = 2.8182845830E-04

```

First e2 is solved with respect to x2, then e1 is solved with respect to x1 as indicated by the last part of the output. At this point all variables that appear in equation e4, namely x1 and x2, are fixed, but the equation is not feasible. e4 is therefore inconsistent with e1 and e2 as indicated by the first part of the output. In this case the inconsistency is fairly small, 2.8E-04, so it could be a tolerance problem. CONOPT will always report the tolerance that was used, `rtnwtr` - the triangular Newton tolerance, and if the infeasibility is small it will also tell how the tolerance can be relaxed. Section [The CONOPT Options File](#) gives further details on how to change tolerances, and a complete list of options is given in [Appendix B](#).

You can turn the identification and solution of pre-triangular variables and equations off by adding the line `lspret = f` in the CONOPT control program. This can be useful in some special cases where the point defined by the pre-triangular equations gives a function evaluation error in the remaining equations. The following example shows this:

```

Variable x1, x2, x3, x4, obj;
Equation e1, e2, e3, e4;
e1 .. Log(1+x1) + x2 =e= 0;
e2 .. 5 * x2 =e= -3;
e3 .. obj =e= 1*Sqr(x1) + 2*Sqr(0.01 + x2 - x4) + 3*Sqr(x3);
e4 .. x4 =l= x2;
Model fer / All /; Solve fer Minimizing obj using NLP;

```

All the nonlinear functions are defined in the initial point in which all variables have their default value of zero. The pre-processor will compute $x2 = -0.6$ from e2 and $x1 = 0.822$ from e1. When CONOPT continues and attempts to evaluate e3, the argument to the Sqrt function is negative when these new triangular values are used together with the initial $x4 = 0$, and CONOPT cannot backtrack to some safe point since the function evaluation error appears the first time e3 is evaluated. When the pre-triangular preprocessor is turned off, x2 and x4 are changed at the same time and the argument to the Sqrt function remains positive throughout the computations. Note, that although the purpose of the e4 inequality is to guarantee that the argument of the Sqrt function is positive in all points, and although e4 is satisfied in the initial point, it is not satisfied after the pre-triangular constraints have been solved. Only simple bounds are strictly enforced at all times. Also note that if the option `lspret = f` is used then feasible linear constraints will in fact remain feasible.

An alternative (and preferable) way of avoiding the function evaluation error is to define an intermediate variable equal to $0.01+x2-x4$ and add a lower bound of 0.01 on this variable. The inequality e4 could then be removed and the overall model would have the same number of constraints.

5.11.8.4.2 Preprocessing: Post-triangular Variables and Constraints Consider the following fragment of a larger GAMS model:

```

Variable util(t)  Utility in period t
              totutil  Total Utility;
Equation utilDef(T) Definition of Utility
              tutilDef  Definition of Total Utility;
utilDef(T).. util(t) =e= nonlinear function of other variables;
tutilDef .. totutil =e= Sum( t , util(t) / (1+r)**Ord(t) );
Model demo / All /; Solve demo Maximizing totutil using NLP;

```

The part of the model shown here is easy to read and from a modeling point of view it should be considered well written. However, it could be more difficult to solve than a model in which variable `util(t)` was substituted out because all the `utilDef` equations are nonlinear constraints that the algorithms must ensure are satisfied.

To make well written models like this easy to solve CONOPT will move as many nonlinearities as possible from the constraints to the objective function. This automatically changes the model from the form that is preferable for the modeler to the form that is preferable for the algorithm. In this process CONOPT looks for free variables that only appear in one equation outside the objective function. If such a variable exists and it appears linearly in the equation, like `util(t)` appears with coefficient 1 in equation `utilDef(t)`, then the equation can always be solved with respect to the variable. This means that the variable logically can be substituted out of the model and the equation can be removed. The result is a model that has one variable and one equation less, and a more complex objective function. As variables and equations are substituted out, new candidates for elimination may emerge, so CONOPT repeats the process until no more candidates exist.

This so-called post-triangular preprocessing step will often move several nonlinear constraints into the objective function where they are much easier to handle, and the effective size of the model will decrease. In some cases the result can even be a model without any general constraints. The name post-triangular is derived from the way the equations and variables appear in the permuted Jacobian in [Figure 1](#). The post-triangular equations and variables are the ones on the lower right hand corner labeled B and II, respectively.

In the example above, the `util` variables will be substituted out of the model together with the nonlinear `utilDef` equations provided the `util` variables are free and do not appear elsewhere in the model. The resulting model will have fewer nonlinear constraints, but more nonlinear terms in the objective function.

Although you may know that the nonlinear functions on the right hand side of `utilDef` always will produce positive `util` values, you should in general not declare `util` to be a Positive Variable. If you do, GAMS/CONOPT may not be able to eliminate `util(t)`, and the model will be harder to solve. It is of course unfortunate that a redundant bound changes the solution behavior, and to reduce this problem CONOPT will try to estimate the range of nonlinear expressions using interval arithmetic. If the computed range of the right hand side of the `utilDef` constraint is within the bounds of `util`, then these bounds cannot be binding and `util` is a so-called implied free variable that can be eliminated.

The following model fragment from a least squares model shows another case where the preprocessing step in GAMS/CONOPT is useful:

```
Variable residual(case)  Residuals
      ssq                Sum of Squared Residuals;
Equation eqEst(case)     Equation to be estimated
      ssqDef             Definition of objective;
eqEst(case).. residual(case) =e= expression in other variables;
SSQDEF      .. ssq =e= Sum( case, Sqr( residual(case) ) );
Model lsqLarge / All /; Solve lsqLarge using NLP Minimizing ssq;
```

GAMS/CONOPT will substitute the residual variables out of the model using the `eqEst` equations. The model solved by GAMS/CONOPT is therefore mathematically equivalent to the following GAMS model

```
Variable ssq            Sum of Squared Residuals;
Equation ssqd           Definition of objective;
ssqd .. ssq =e= Sum( case, Sqr(expression in other variables));
Model lsqSmall / All /;
Solve lsqSmall using NLP Minimizing ssq;
```

However, if the "expression in other variables" is a little complicated, e.g. if it depends on several variables, then the first model, `lsqLarge`, will be much faster to generate with GAMS because its derivatives in equation `qEst` and `ssqDef` are much simpler than the derivatives in the combined `ssqDef` equation in the second model, `lsqSmall`. The larger model will therefore be faster to generate, and it will also be faster to solve because the computation of both first and second derivatives will be faster.

Note that the comments about what are good model formulations are dependent on the preprocessing capabilities in GAMS/CONOPT. Other algorithms may prefer models like `lsqSmall` over `lsqLarge`. Also note that the variables and equations that are substituted out are still indirectly part of the model. GAMS/CONOPT evaluates the equations and computes values for the variables each time the value of the objective function is needed, and their values are available in the GAMS solution.

It is not necessary to have a coefficient of 1 for the variable to be substituted out in the post-triangular phase. However, a non-zero coefficient cannot be smaller than the absolute pivot tolerance used by CONOPT, `rtpiva`.

The number of pre- and post-triangular equations and variables is printed in the log file between iteration 0 and 1 as shown in the iteration log in section [Iteration Output](#) of the main text. The sum of infeasibilities will usually decrease from iteration 0 to 1 because fewer constraints usually will be infeasible. However, it may increase as shown by the following example:

```
Positive Variable x, y, z;
Equation e1, e2;
e1.. x =e= 1;
e2.. 10*x - y + z =e= 0;
```

started from the default values $x.L = 0$, $y.L = 0$, and $z.L = 0$. The initial sum of infeasibilities is 1 (from `e1` only). During pre-processing `x` is selected as a pre-triangular variable in equation `e1` and it is assigned its final value 1 so `e1` becomes feasible. After this change the sum of infeasibilities increases to 10 (from `e2` only).

You may stop CONOPT after iteration 1 with `Option IterLim = 1;` in GAMS. The solution returned to GAMS will contain the pre-processed values for the variables that can be assigned values from the pre-triangular equations, the computed values for the variables used to solve the post-triangular equations, and the input values for all other variables. The pre- and post-triangular constraints will be feasible, and the remaining constraints will have values that correspond to this point. The marginals of both variables and equations have not been computed yet and will be returned as EPS.

The crash procedure described in the following sub-section is an optional part of iteration 1.

5.11.8.4.3 Preprocessing: The Optional Crash Procedure In the initial point given to CONOPT the variables are usually split into a group with initial value provided by the modeler (in the following called the assigned variables) and a group of variables for which no initial value has been provided (in the following called the default variables). The objective of the optional crash procedure is to find a point in which as many of the constraints as possible are feasible, primarily by assigning values to the default variables and by keeping the assigned variables at their initial values. The implicit assumption in this procedure is that if the modeler has assigned an initial value to a variable then this value is "better" than a default initial value.

The crash procedure is an extension of the triangular pre-processing procedure described above and is based on a simple heuristic: As long as there is an equation with only one non-fixed variable (a singleton row) then we should assign a value to the variable so the equation is satisfied or satisfied as closely as possible, and we should then temporarily fix the variable. When variables are fixed additional singleton rows may emerge and we repeat the process. When there are no singleton rows we fix one or more variables at their initial value until a singleton row appears, or until all variables have been fixed. The variables to be fixed at their initial value are selected using a heuristic that both tries to create many row singletons

and tries to select variables with "good values". Since the values of many variables will come to depend in the fixed variables, the procedure favors assigned variables and among these it favors variables that appear in many feasible constraints.

Figure 2 shows a reordered version of Figure 1. The variables labeled IV are the variables that are kept at their initial values, primarily selected from the assigned variables. The equations labeled C are then solved with respect to the variables labeled III, called the crash-triangular variables. The crash-triangular variables will often be variables without initial values, e.g. intermediate variables. The number of crash-triangular variables is shown on the iteration output between iteration 0 and 1, but only if the crash procedure is turned on.

The result of the crash procedure is an updated initial point in which usually a large number of equations will be feasible, namely all equations labeled A, B, and C in Figure 2. There is, as already shown with the small example in Section [Preprocessing: Post-triangular Variables and Constraints](#) above, no guarantee that the sum of infeasibilities will be reduced, but it is often the case, and the point will often provide a good starting point for the following procedures that finds an initial feasible solution.

The crash procedure is activated by adding the line `lstcrs=t` in the options file. The default value of `lstcrs` (`lstcrs` = Logical Switch for Triangular Crash) is `f` or `false`, i.e. the crash procedure is not normally used. Before turning the crash procedure on you must turn the definitional equations (see next sub-section) off.

5.11.8.4.4 Preprocessing: Definitional Equations From version 3.16 CONOPT has introduced the concept of Definitional Equations. In section [Simple Expressions](#) it was recommended to introduce intermediate variables to simplify complex expressions. If the intermediate variables are free or if the bounds defined by the modeler cannot be binding then we call the constraints that define the intermediate variables "Definitional Equations" and the intermediate variables "Defined Variables". Some models have a large number of definitional equations, and CONOPT tries to recognize them and take advantage of the special structure. Defined variables that only appear in or feed into the objective are recognized as post-triangular variables as discussed in section [Preprocessing: Post-triangular Variables and Constraints](#) but defined variables can also be used in the simultaneous constraints. The picture is similar to fig 2. with the C-rows representing the definitional constraints and the III-variables the defined variables. The main differences between crash- triangular variables and defined variable are that (1) defined variables are free or have non-binding bounds and the definitional equations can therefore always be made feasible, (2) defined variables are cheaper to recognize, (3) since they have a natural interpretation, using them is probably more numerical stable, and (4) there are most likely fewer defined variables than crash-triangular variables.

The number of definitional equations is printed in the log file between iteration 0 and 1 if CONOPT finds any. The definitional equations are used to give the defined variables new values, so it is no longer so important the give intermediate variables initial values. In the process the sum of infeasibilities may grow but CONOPT consider it more important to keep these constraints feasible. The defined variables are also made basic and they will most likely stay basic throughout the solution process.

There are three new options introduced to controls the detection of definitional equations: `lsusdf`, `lsuqdf`, and `lfusdf`. They are described in [Appendix B](#). By default CONOPT will only look for unique definitional constraints, but the options allow the user to experiment with a more aggressive strategy.

From version 3.16F there is an additional option, `lmusdf`, used to control how the definitional equations are used during the optimization. The option is summarized in [Appendix B](#). By default, definitional equations are only used to define initial values and an initial basis and their special properties are ignored during the optimization. If there are many definitional equations and they are fairly nonlinear then it can sometimes be beneficial to force the definitional variables to remain basic and to use the definitional equations to compute values for the defined variables in all intermediate trial points. This behavior is turned on with `lmusdf = 1`. The point where `lmusdf = 1` start to pay off depends on the model and the degree of nonlinearity, but a guess is that the number of definitional equations should exceed half the number of equations remaining after the pre- and post-triangular equations have been removed before it is worth while.

5.11.8.5 Iteration 2: Scaling

Iteration 2 is the last dummy iteration during which the model is scaled, if scaling is turned on. The default is to turn scaling on. The Infeasibility column shows the scaled sum of infeasibilities. You may again stop CONOPT after iteration 2 with `Option IterLim = 2;` in GAMS, but the solution that is reported in GAMS will have been scaled back again so there will be no change from iteration 1 to iteration 2.

The following description of the automatic scaling procedure is included for completeness. Experiments have so far given mixed results with some advantage for scaling, and scaling is therefore by default turned on, corresponding to the CONOPT option `lsscal = t`. Users are recommended to be cautious with the automatic scaling procedure. If scaling is a problem, try to use manual scaling or scaling in GAMS (see section [Scaling](#) in the main text) based on an understanding of the model.

The scaling procedure multiplies all variables in group III and all constraints in group C (see [Figure 1](#)) by scale factors computed as follows:

1. CONOPT computes the largest term for each constraint, i. This is defined as the maximum of the constant right hand side, the slack (if any), and $\text{Abs}(\text{jac}(i,j)*x(j))$ where $\text{jac}(i,j)$ is the derivative and $x(j)$ is the variable.
2. The constraint scale factor is defined as the largest term in the constraint, projected on the interval `[rtmins, rtmaxs]`. The constraint is then divided by the constraint scale factor. Ignoring the projection, the result is a model in which the largest term in each constraint is exactly 1. The purpose of the projection is to prevent extreme scaling. The default value of `rtmins` is 1 which implies that we do not scale the constraints up. Constraints with only small terms remain unchanged. The default value of `rtmaxs` is $2^{**}30$ or around $1.07e9$ so terms much larger than $1.e9$ are only partially scaled down and will still remain large.
3. The terms $\text{Abs}(\text{jac}(i,j)*x(j))$ after constraint scaling measure the importance of each variable in the particular constraint. The variable scale is selected so the largest importance of the variable over all constraints is 1. This gives a very simple variable scale factor, namely the absolute value of the variable. The variable is then divided by the variable scale factor. To avoid extreme scaling we again project on the interval `[rtmins, rtmaxs]`. Variables less than `rtmins` (default 1) are therefore not scaled up and variables over `rtmaxs` (default $2^{**}30 = 1.07e9$) are only partially scaled down.

You should note that CONOPT by default scales large numbers down, but it does not scale small numbers up. You should therefore try to avoid having variables or terms in expressions that are small but significant. If this is not possible, allow CONOPT to scale up by giving the option `rtmins` a value less than 1.

All scale factors are rounded down to a power of 2 to preserve precision in the internal computations. To avoid difficulties with rapidly varying variables and derivatives CONOPT recomputes the scale factors at regular intervals (see `lfscal`).

The options that control scaling, `lsscal`, `lfscal`, `rtmins`, and `rtmaxs`, are all described in [Appendix B](#).

5.11.8.6 Finding a Feasible Solution: Phase 0

The GRG algorithm used by CONOPT is a feasible path algorithm. This means that once it has found a feasible point it tries to remain feasible and follow a path of improving feasible points until it reaches a local optimum. CONOPT starts with the point provided by GAMS. This point will always satisfy the bounds (3): GAMS will simply move a variable that is outside its bounds to the nearer bound before it is presented to the solver. If the general constraints (2) also are feasible then CONOPT will work with feasible solutions throughout the optimization. However, the initial point may not satisfy the general constraints (2). If this is not the case, GAMS/CONOPT must first find an initial feasible point. This first

step can be just as hard as finding an optimum for some models. For some models feasibility is the only problem.

GAMS/CONOPT has two methods for finding an initial feasible point. The first method is not very reliable but it is fast when it works; the second method is reliable but slower. The fast method is called Phase 0 and it is described in this section. It is used first. The reliable method, called Phase 1 and 2, will be used if Phase 0 terminates without a feasible solution.

Phase 0 is based on the observation that Newton's method for solving a set of equations usually is very fast, but it may not always converge. Newton's method in its pure form is defined for a model with the same number of variables as equations, and no bounds on the variables. With our type of model there are usually too many variables, i.e. too many degrees of freedom, and there are bounds. To get around the problem of too many variables, GAMS/CONOPT selects a subset with exactly m "basic" variables to be changed. The rest of the variables will remain fixed at their current values, that are not necessarily at bounds. To accommodate the bounds, GAMS/CONOPT will try to select variables that are away from their bounds as basic, subject to the requirement that the Basis matrix, consisting of the corresponding columns in the Jacobian, must have full rank and be well conditioned.

The Newton equations are solved to yield a vector of proposed changes for the basic variables. If the full proposed step can be applied we can hope for the fast convergence of Newton's method. However, several things may go wrong:

1. The infeasibilities, measured by the 1-norm of g (i.e. the sum of the absolute infeasibilities, excluding the pre- and post-triangular equations), may not decrease as expected due to nonlinearities.
2. The maximum step length may have to be reduced if a basic variable otherwise would exceed one of its bounds.

In case 1. GAMS/CONOPT tries various heuristics to find a more appropriate set of basic variables. If this does not work, some "difficult" equations, i.e. equations with large infeasibilities and significant nonlinearities, are temporarily removed from the model, and Newton's method is applied to the remaining set of "easy" equations.

In case 2. GAMS/CONOPT will remove the basic variable that first reaches one of its bounds from the basis and replace it by one of the nonbasic variables. Newton's method is then applied to the new set of basic variables. The logic is very close to that of the dual simplex method. In cases where some of the basic variables are exactly at a bound GAMS/CONOPT uses an anti degeneracy procedure based on Ryan and Osborne (1988) to prevent cycling.

Phase 0 will end when all equations except possibly some "difficult" equations are feasible within some small tolerance. If there are no difficult equations, GAMS/CONOPT has found a feasible solution and it will proceed with Phase 3 and 4. Otherwise, Phase 1 and 2 is used to make the difficult equations feasible.

The iteration output will during Phase 0 have the following columns in the iteration log: Iter, Phase, Ninf, Infeasibility, Step, MX, and OK. The number in the Ninf column counts the number of "difficult" infeasible equations, and the number in the Infeasibility column shows the sum of the absolute infeasibilities in all the general constraints, both in the easy and in the difficult ones. There are three possible combinations of values in the MX and OK columns: combination (1) has F in the MX column and T in the OK column and it will always be combined with 1.0 in the Step column: this is an ideal Newton step. The infeasibilities in the easy equations should be reduced quickly, but the difficult equations may dominate the number in the Infeasibility column so you may not observe it. However, a few of these iterations is usually enough to terminate Phase 0. Combination (2) has T in the MX column indicating that a basic variable has reached its bound and is removed from the basis as in case 2. above. This will always be combined with T in the OK column. The Step column will show a step length less than the ideal Newton step of 1.0. Combination (3) has F in both the MX and OK column. It is the bad case and will always be combined with a step of 0.0: this is an iteration where nonlinearities are dominating and one of the heuristics from case 1. must be used.

The success of the Phase 0 procedure is based on being able to choose a good basis that will allow a full Newton step. It is therefore important that as many variables as possible have been assigned reasonable initial values so GAMS/CONOPT has some variables away from their bounds to select from. This topic was discussed in more detail in section [Initial Values](#).

The start and the iterations of Phase 0 can, in addition to the crash option described in section [Finding a Feasible Solution: Phase 0](#) be controlled with the three options `lslack`, `lsmxbs`, and `lmmxsf` described in [Appendix B](#).

5.11.8.7 Finding a Feasible Solution: Phase 1 and 2

Most of the equations will be feasible when phase 0 stops. To remove the remaining infeasibilities CONOPT uses a procedure similar to the phase 1 procedure used in Linear Programming: artificial variables are added to the infeasible equations (the equations with Large Residuals), and the sum of these artificial variables is minimized subject to the feasible constraints remaining feasible. The artificial variables are already part of the model as slack variables; their bounds are simply relaxed temporarily.

This infeasibility minimization problem is similar to the overall optimization problem: minimize an objective function subject to equality constraints and bounds on the variables. The feasibility problem is therefore solved with the ordinary GRG optimization procedure. As the artificial variables gradually become zero, i.e. as the infeasible equations become feasible, they are taken out of the auxiliary objective function. The number of infeasibilities (shown in the `Ninf` column of the log file) and the sum of infeasibilities (in the `Infeasibility` column) will therefore both decrease monotonically.

The iteration output will label these iterations as phase 1 and/or phase 2. The distinction between phases 1 (linear mode) and 2 (nonlinear mode) is similar to the distinction between phases 3 and 4, which are described in the next sections.

5.11.8.8 Linear and Nonlinear Mode: Phase 1 to 4

The optimization itself follows step 2 to 9 of the GRG algorithm shown in [The CONOPT Algorithm](#) above. The factorization in step 3 is performed using an efficient sparse LU factorization similar to the one described by Suhl and Suhl (1990). The matrix operations in step 4 and 5 are also performed sparse.

Step 7, selection of the search direction, has several variants, depending on how nonlinear the model is locally. When the model appears to be fairly linear in the area in which the optimization is performed, i.e. when the function and constraint values are close to their linear approximation for the steps that are taken, then CONOPT takes advantage of the linearity: The derivatives (the Jacobian) are not computed in every iteration, the basis factorization is updated using cheap LP techniques as described by Reid (1982), the search direction is determined without use of second order information, i.e. similar to a steepest descent algorithm, and the initial steplength is estimated as the step length where the first variable reaches a bound; very often, this is the only step length that has to be evaluated. These cheap almost linear iterations are referred to a Linear Mode and they are labeled Phase 1 when the model is infeasible and objective is the sum of infeasibilities and Phase 3 when the model is feasible and the real objective function is optimized.

When the constraints and/or the objective appear to be more nonlinear CONOPT will still follow step 2 to 9 of the GRG algorithm. However, the detailed content of each step is different. In step 2, the Jacobian must be recomputed in each iteration since the nonlinearities imply that the derivatives change. On the other hand, the set of basic variables will often be the same and CONOPT will take advantage of this during the factorization of the basis. In step 7 CONOPT uses the BFGS algorithm to estimate second order information and determine search directions. And in step 8 it will often be necessary to perform more than one step in the line search. These nonlinear iterations are labeled Phase 2 in the output if the solution is still infeasible, and Phase 4 if it is feasible. The iterations in phase 2 and 4 are in general more expensive than the iteration in phase 1 and 3.

Some models will remain in phase 1 (linear mode) until a feasible solution is found and then continue in phase 3 until the optimum is found, even if the model is truly nonlinear. However, most nonlinear models will have some iterations in phase 2 and/or 4 (nonlinear mode). Phase 2 and 4 indicates that the model has significant nonlinear terms around the current point: the objective or the constraints deviate significantly from a linear model for the steps that are taken. To improve the rate of convergence CONOPT tries to estimate second order information in the form of an estimated reduced Hessian using the BFGS formula.

Each iteration is, in addition to the step length shown in column "Step", characterized by two logicals: MX and OK. MX = T means that the step was maximal, i.e. it was determined by a variable reaching a bound. This is the expected value in Phase 1 and 3. MX = F means that no variable reached a bound and the optimal step length will in general be determined by nonlinearities. OK = T means that the line search was well-behaved and an optimal step length was found; OK = F means that the line search was ill-behaved, which means that CONOPT would like to take a larger step, but the feasibility restoring Newton process used during the line search did not converge for large step lengths. Iterations marked with OK = F (and therefore also with MX = F) will usually be expensive, while iterations marked with MX = T and OK = T will be cheap.

5.11.8.9 Linear Mode: The SLP Procedure

When the model continues to appear linear CONOPT will often take many small steps, each determined by a new variable reaching a bound. Although the line searches are fast in linear mode, each require one or more evaluations of the nonlinear constraints, and the overall cost may become high relative to the progress. In order to avoid the many nonlinear constraint evaluations CONOPT may replace the steepest descend direction in step 7 of the GRG algorithm with a sequential linear programming (SLP) technique to find a search direction that anticipates the bounds on all variables and therefore gives a larger expected change in objective in each line search. The search direction and the last basis from the SLP procedure are used in an ordinary GRG-type line search in which the solution is made feasible at each step. The SLP procedure is only used to generate good directions; the usual feasibility preserving steps in CONOPT are maintained, so CONOPT is still a feasible path method with all its advantages, especially related to reliability.

Iterations in this so-called SLP-mode are identified by numbers in the column labeled `InItr` in the iteration log. The number in the `InItr` column is the number of non- degenerate SLP iterations. This number is adjusted dynamically according to the success of the previous iterations and the perceived linearity of the model.

The SLP procedure generates a scaled search direction and the expected step length in the following line search is therefore 1.0. The step length may be less than 1.0 for several reasons:

- The line search is ill-behaved. This is indicated with OK = F and MX = F.
- A basic variable reaches a bound before predicted by the linear model. This is indicated with MX = T and OK = T.
- The objective is nonlinear along the search direction and the optimal step is less than one. This is indicated with OK = T and MX = F.

CONOPT will by default determine if it should use the SLP procedure or not, based on progress information. You may turn it off completely with the line `lseslp = f` in the CONOPT options file (usually *conopt.opt*). The default value of `lseslp` (`lseslp` = Logical Switch Enabling SLP mode) is `t` or `true`, i.e. the SLP procedure is enabled and CONOPT may use it when considered appropriate. It is seldom necessary to define `lseslp`, but it can be useful if CONOPT repeatedly turns SLP on and off, i.e. if you see a mixture of lines in the iteration log with and without numbers in the `InItr` column.

5.11.8.10 Linear Mode: The Steepest Edge Procedure

When optimizing in linear mode (Phase 1 or 3) CONOPT will by default use a steepest descend algorithm to determine the search direction. CONOPT allows you to use a Steepest Edge Algorithm as an alternative. The idea, borrowed from Linear Programming, is to scale the nonbasic variables according to the Euclidean norm of the "updated column" in a standard LP tableau, the so-called edge length. A unit step for a nonbasic variable will give rise to changes in the basic variables proportional to the edge length. A unit step for a nonbasic variable with a large edge length will therefore give large changes in the basic variables which has two adverse effects relative to a unit step for a nonbasic variable with a small edge length: a basic variable is more likely to reach a bound after a very short step length, and the large change in basic variables is more likely to give rise to larger nonlinear terms.

The steepest edge algorithm has been very successful for linear programs, and our initial experience has also shown that it will give fewer iterations for most nonlinear models. However, the cost of maintaining the edge lengths can be more expensive in the nonlinear case and it depends on the model whether steepest edge results in faster overall solution times or not. CONOPT uses the updating methods for the edge lengths from LP, but it must re-initialize the edge lengths more frequently, e.g. when an inversion fails, which happens more frequently in nonlinear models than in linear models, especially in models with many product terms, e.g. blending models, where the rank of the Jacobian can change from point to point.

Steepest edge is turned on with the line, `lsanrm = t`, in the CONOPT options file (usually *conopt.opt*). The default value of `lsanrm` (`lsanrm` = Logical Switch for A- Norm) is `f` or `false`, i.e. the steepest edge procedure is turned off.

The steepest edge procedure is mainly useful during linear mode iterations. However, it has some influence in phase 2 and 4 also: The estimated reduced Hessian in the BFGS method is initialized to a diagonal matrix with elements on the diagonal computed from the edge lengths, instead of the usual scaled unit matrix.

5.11.8.11 Nonlinear Mode: The SQP Procedure

When progress is determined by nonlinearities CONOPT needs second order information. Some second order information can be derived from the line search and is used in the first iterations in Phase 2 or 4. Depending on progress, CONOPT may switch to a Sequential Quadratic Programming (SQP) procedure that works on a sub-model with linear constraints and a quadratic objective function. The constraints are a linearization of the nonlinear constraints, and the objective function is derived from the Hessian of the Lagrangian function. CONOPT will inside the SQP procedure use exact second order information computed by GAMS. The result of the SQP procedure is a search direction and a basis and CONOPT will afterwards use the same line search procedure and feasibility preserving steps as after the SLP procedure. CONOPT remains a feasible path method with all its advantages, especially related to reliability.

Iterations in this so-called SQP-mode are identified by numbers in the column labeled "InItr" in the iteration log. The number in the InItr column is the number of non-degenerate SQP iterations. The effort spend inside the SQP procedure is adjusted dynamically according to the success of the previous iterations and the reduction in reduced gradient in the quadratic model.

The SQP procedure generates a scaled search direction and the expected step length in the following line search is therefore 1.0. The step length may be less than 1.0 for several reasons:

- The line search is ill-behaved. This is indicated with `OK = F` and `MX = F`.
- A basic variable reaches a bound before predicted by the linear model of the constraints. This is indicated with `MX = T` and `OK = T`.
- The objective is much more nonlinear along the search direction than expected and the optimal step is not one. This is indicated with `OK = T` and `MX = F`.

CONOPT will by default determine if it should use the SQP procedure or not, based on progress information. You may turn it off completely with the line `lsesqp = f` in the CONOPT options file (usually `conopt.opt`). The default value of `lsesqp` (`lsesqp` = Logical Switch Enabling SQP mode) is `t` or `true`, i.e. the SQP procedure is enabled and CONOPT may use it when considered appropriate. It is seldom necessary to define `lsesqp`, but it can be used for experimentation.

In connection with 1st and 2nd derivatives the listing file (*.lst) will have a few extra lines. The first looks as follows:

```
The model has 537 variables and 457 constraints
with 1597 Jacobian elements, 380 of which are nonlinear.
The Hessian of the Lagrangian has 152 elements on the diagonal,
228 elements below the diagonal, and 304 nonlinear variables.
```

The first two lines repeat information given in the GAMS model statistics and the last two lines describe second order information. CONOPT uses the matrix of second derivatives (the Hessian) of a linear combination of the objective and the constraints (the Lagrangian). The Hessian is symmetric and the statistics show that it has 152 elements on the diagonal and 228 below for a total of 380 elements in this case. This compares favorably to the number of elements in the matrix of first derivatives (the Jacobian).

For some models you may see the following message instead (before the usual CONOPT banner):

```
** Warning ** Memory Limit for Hessians exceeded.
You can use the Conopt option "rvhess"
```

The creation of the matrix of second derivatives has been interrupted because the matrix became too dense. A dense matrix of second derivatives will be slow to compute and it will need a lot of memory. In addition, it is likely that a dense Hessian will make some of the computations inside the SQP iterations so slow that the potential saving in number of iterations is used up computing and manipulating the Hessian.

GAMS/CONOPT can use second derivatives even if the Hessian is not available. A special version of the function evaluation routine can compute the Hessian multiplied by a vector (the so-called directional second derivative) without computing the Hessian itself. This routine is used when the Hessian is not available. The directional second derivative approach will require one directional second derivative evaluation call per inner SQP iteration instead of one Hessian evaluation per SQP sub-model.

If you get the "Memory Limit for Hessians exceeded" message you may consider rewriting some equation. Look for nonlinear functions applied to long linear or separable expressions such as `log(sum(i,x(i)))`; as discussed in Section [Simple Expressions](#) . An expression like this will create a dense Hessian with `card(i)` rows and columns. You should consider introducing an intermediate variable that is equal to the long linear or separable expression and then apply the nonlinear function to this single variable. You may also experiment with allocating more memory for the dense Hessian and use it despite the higher cost; it may reduce the number of iterations. This can be done by adding the option `rvhess = XX` to the CONOPT options file. `rvhess` is a memory factor with default value 10 so you need a larger value. The value 0.0 is special; it means do not impose a memory limit on the Hessian.

The time spend on the many types of function and derivative evaluations are reported in the listing file in a section like this:

CONOPT time Total	0.734 seconds
of which: Function evaluations	0.031 = 4.3%
1st Derivative evaluations	0.020 = 2.7%
2nd Derivative evaluations	0.113 = 15.4%
Directional 2nd Derivative	0.016 = 2.1%

The function evaluations are computations of the nonlinear terms in the model, and 1st Derivatives evaluations are computations of the Jacobian of the model. 2nd Derivative evaluations are computations of the Hessian of the Lagrangian, and Directional 2nd derivative evaluations are computations of the Hessian multiplied by a vector, computed without computing the Hessian itself. The lines for 2nd derivatives will only be present if CONOPT has used this type of 2nd derivative.

If your model is not likely to benefit from 2nd derivative information or if you know you will run out of memory anyway you can save a small setup cost by telling GAMS/CONOPT not to generate it using option `dhess = f`.

5.11.8.12 How to Select Non-default Options

The non-default options have an influence on different phases of the optimization and you must therefore first observe whether most of the time is spend in Phase 0, Phase 1 and 3, or in Phase 2 and 4.

Phase 0: The quality of Phase 0 depends on the number of iterations and on the number and sum of infeasibilities after Phase 0. The iterations in Phase 0 are much faster than the other iterations, but the overall time spend in Phase 0 may still be rather large. If this is the case, or if the infeasibilities after Phase 0 are large you may try to use the triangular crash options:

```
lstcrs = t
```

Observe if the initial sum of infeasibility after iteration 1 has been reduced, and if the number of phase 0 iterations and the number of infeasibilities at the start of phase 1 have been reduced. If lstcrs reduces the initial sum of infeasibilities but the number of iterations still is large you may try:

```
lslack = t
```

CONOPT will after the preprocessor immediately add artificial variables to all infeasible constraints so Phase 0 will be eliminated, but the sum and number of infeasibilities at the start of Phase 1 will be larger. You are in reality trading Phase 0 iterations for Phase 1 iterations.

You may also try the experimental bending line search with

```
lmmxsf = 1
```

The line search in Phase 0 will with this option be different and the infeasibilities may be reduced faster than with the default `lmmxsf = 0`. It is likely to be better if the number of iterations with both `MX = F` and `OK=∼F` is large. This option may be combined with `lstcrs = t`. Usually, linear constraints that are feasible will remain feasible. However, you should note that with the bending linesearch linear feasible constraints could become infeasible.

Phase 1 and 3: The number of iterations in Phase 1 and Phase 3 will probably be reduced if you use steepest edge, `lsanrm = t`, but the overall time may increase. Steepest edge seems to be best for models with less than 5000 constraints, but work in progress tries to push this limit upwards. Try it when the number of iterations is very large, or when many iterations are poorly behaved identified with `OK = F` in the iteration log. The default SLP mode is usually an advantage, but it is too expensive for a few models. If you observe frequent changes between SLP mode and non-SLP mode, or if many line searches in the SLP iterations are ill-behaved with `OK = F`, then it may be better to turn SLP off with `lseslp = f`.

Phase 2 and 4: There are currently not many options available if most of the time is spend in Phase 2 and Phase 4. If the change in objective during the last iterations is very small, you may reduce computer time in return for a slightly worse objective by reducing the optimality tolerance, `rtredg`.

5.11.8.13 Miscellaneous Topics

5.11.8.13.1 Triangular Models A triangular model is one in which the non-fixed variables and the equations can be sorted such that the first equation only depends on the first variable, the second equation only depends on the first two variables, and the p -th equation only depends on the first p variables. Provided there are no difficulties with bounds or small pivots, triangular models can be solved one equation at a time using the method describe in section [Preprocessing: Pre-triangular Variables and Constraints](#) and the solution process will be very fast and reliable.

Triangular models can in many cases be useful for finding a good initial feasible solution: Fix a subset of the variables so the remaining model is known to be triangular and solve this triangular simulation model. Then reset the bounds on the fixed variables to their original values and solve the original model. The first solve will be very fast and if the fixed variables have been fixed at good values then the solution will also be good. The second solve will start from the good feasible solution generated by the first solve and it will usually optimize much more quickly than from a poor start.

The modeler can instruct CONOPT that a model is supposed to be triangular with the option `lstria = t`. CONOPT will then use a special version of the preprocessing routine (see section [Preprocessing: Pre-triangular Variables and Constraints](#)) that solves the model very efficiently. If the model is solved successfully then CONOPT terminates with the message:

```
** Feasible solution to a recursive model.
```

and the Model Status will be 2, Locally Optimal, or 1, Optimal, depending on whether there were any nonlinear pivots or not. All marginals on both variables and equations are returned as 0 (zero) or EPS.

Two SOLVEs with different option files can be arranged by writing the option files as they are needed from within the GAMS program with PUT statements followed by a PutClose. You can also have two different option files, e.g., *conopt.opt* and *conopt.op2*, and select the second with the GAMS statement `<model>.OptFile = 2;`

The triangular facility handles a number of error situations:

1. Non-triangular models: CONOPT will ensure that the model is indeed triangular. If it is not, CONOPT will return model status 5, Locally Infeasible, plus some information that allows the modeler to identify the mistake. The necessary information is related to the order of the variables and equations and number of occurrences of variables and equations, and since GAMS does not have a natural place for this type of information CONOPT returns it in the marginals of the equations and variables. The solution order for the triangular equations and variables that have been solved successfully are defined with positive numbers in the marginals of the equations and variables. For the remaining non-triangular variables and equations CONOPT shows the number of places they appear as negative numbers, i.e. a negative marginal for an equation shows how many of the non-triangular variables that appear in this equation. You must fix one or more variables until at least one of the non-triangular equation only has one non-fixed variable left.
2. Infeasibilities due to bounds: If some of the triangular equations cannot be solved with respect to their variable because the variable will exceed the bounds, then CONOPT will flag the equation as infeasible, keep the variable at the bound, and continue the triangular solve. The solution to the triangular model will therefore satisfy all bounds and almost all equations. The termination message will be

```
** Infeasible solution. xx artificial(s) have been
    introduced into the recursive equations.
```

and the model status will be 5, Locally Infeasible.

The modeler may in this case add explicit artificial variables with high costs to the infeasible constraints and the resulting point will be an initial feasible point to the overall optimization model. You will often from the mathematics of the model know that only some of the constraints can be infeasible, so you will only need to check whether to add artificials in these equations. Assume that a block of equations `matbal(m,t)` could become infeasible. Then the artificials that may be needed in this equation can be modeled and identified automatically with the following GAMS constructs:

```

Set aposart(m,t) Add a positive artificial in Matbal
    anegart(m,t) Add a negative artificial in Matbal;
aposart(m,t) = No; anegart(m,t) = No;

Positive Variable
    vposart(m,t) Positive artificial variable in Matbal
    vnegart(m,t) Negative artificial variable in Matbal;

matbal(m,t).. Left hand side =e= right hand side
    + vposart(m,t)$aposart(m,t) - vnegart(m,t)$anegart(m,t);

objDef.. obj =e= other_terms +
    weight * Sum((m,t), vposart(m,t)$aposart(m,t)
        + vnegart(m,t)$anegart(m,t) );

Solve triangular model ...

aposart(m,t)$(matbal.l(m,t) > matbal.Up(m,t)) = Yes;
anegart(m,t)$(matbal.l(m,t) < matbal.Lo(m,t)) = Yes;

Solve final model ...

```

3. Small pivots: The triangular facility requires the solution of each equation to be locally unique which also means that the pivots used to solve each equation must be nonzero. The model segment

```

e1 .. x1 =e= 0;
e2 .. x1 * x2 =e= 0;

```

will give the message

```

x2 appearing in
e2: Pivot too small for triangular model. Value=0.000E+00

** Infeasible solution. The equations were assumed to be
    recursive but they are not. A pivot element is too small.

```

However, the uniqueness of `x2` may not be relevant if the solution just is going to be used as an initial point for a second model. The option `lsismp = t` (for Logical Switch: Ignore Small Pivots) will allow zero pivots as long as the corresponding equation is feasible for the given initial values.

5.11.8.13.2 Constrained Nonlinear System or Square Systems of Equations There is a special model class in GAMS called CNS - Constrained Nonlinear System. A constrained nonlinear system is a square system of equations, i.e. a model in which the number of non-fixed variables is equal to the number of constraints. Currently, CONOPT and PATH are the only solvers for this model class. A CNS model can be solved with a `solve` statement like

```
Solve <model> using CNS;
```

without an objective term. In some cases it may be convenient to solve a CNS model with a standard solve statement combined with an options file that has the statement `lssqrs = t`. In the latter case, CONOPT will check that the number of non-fixed variables is equal to the number of constraints. In either case, CONOPT will attempt to solve the constraints with respect to the non-fixed variables using Newton's method. The solution process does not include a lot of the safeguards used for ordinary NLP models and when it work it is often very fast and it uses less memory than for the corresponding NLP model. The lack of safeguards means that the solution process just will stop with an error message in some difficult situations and return the current intermediate infeasible solution. Examples of difficulties are that the Jacobian to be inverted is singular, or if one of the non-fixed variables tries to move outside their bounds as described with examples below.

Slacks in inequalities are counted as non-fixed variables which effectively means that inequalities should not be binding. Bounds on the variables are allowed, especially to prevent function evaluation errors for functions that only are defined for some arguments, but the bounds should not be binding in the final solution.

The solution returned to GAMS will in all cases have marginal values equal to 0 or EPS, both for the variables and the constraints.

The termination messages for CNS models are different from the termination messages for optimization models. The message you hope for is

```
** Feasible solution to a square system.
```

that usually will be combined with model status 16-Solved. If CONOPT in special cases can guarantee that the solution is unique, for example if the model is linear, then the model status will be 15-Solved Unique.

There are two potential error termination messages related to CNS models. A model with the following two constraints

```
e1 ..  x1 +  x2 =e= 1;
e2 .. 2*x1 + 2*x2 =e= 2;
```

will result in the message

```
** Error in Square System: Pivot too small.
    e2: Pivot too small.
    x1: Pivot too small.
```

"Pivot too small" means that the set of constraints is linearly dependent in the current point and there is no unique search direction for Newton's method so CONOPT terminates. The message points to one variable and one constraint. However, this just indicates that the linearly dependent set of constraints and variables include the constraint and variable mentioned. The offending constraint and variable will also be labeled 'DEPND' for linearly dependent in the equation listing. The error will usually be combined with model status 5 - Locally Infeasible. In the cases where CONOPT can guarantee that the infeasibility is not caused by nonlinearities the model status will be 4 - Infeasible. If the constraints are linearly dependent but the current point satisfy the constraints then the solution status will be 17 - Solved Singular, indicating that the point is feasible, but there is probably a whole ray of feasible solution through the current point.

It should be mentioned that the linear dependency and small pivot could be caused by the initial point and that the model could have a solution. An example is

```
e1.. x1*x2 =E= 1;
e2.. x1+x2 =E= 3;
x1.l = 1; x2.l = 1;
```

A model with these two constraints and the bound

```
e1 .. x1 + x2 =e= 2;
e2 .. x1 - x2 =e= 0;
x1.lo = 1.5;
```

will result in the message

```
** Error in Square System: A variable tries to exceed its bound.
   x1: The variable tries to exceed its bound.
```

because the solution, $(x_1, x_2) = (1, 1)$ violates the bound on x_1 . This error case will also be combined with model status 5-Locally Infeasible. In the cases where CONOPT can guarantee that the infeasibility is not caused by nonlinearities the model status will be 4 - Infeasible. If you encounter problems with active bounds but you think it is caused by nonlinearities and that there is a solution, then you may try to use the bending linesearch with option `lmmxsf = t`.

The CNS facility can be used to generate an initial feasible solution in almost the same way as the triangular model facility: Fix a subset of the variables so the remaining model is uniquely solvable, solve this model with the CNS solver or with `lssqrs = t`, reset the bounds on the fixed variables, and solve the original model. The CNS facility can be used on a larger class of models that include simultaneous sets of equations. However, the square system must be non-singular and feasible; CONOPT cannot, like in the triangular case, add artificial variables to some of the constraints and solve the remaining system when a variable reaches one of its bounds.

Additional information on CNS can be found in the [GAMS User's Guide](#).

5.11.8.13.3 Loss of Feasibility During the optimization you may sometimes see a phase 0 iteration and in rare cases you will see the message "Loss of Feasibility - Return to Phase 0". The background for this is as follows:

To work efficiently, CONOPT uses dynamic tolerances for feasibility and during the initial part of the optimization where the objective changes rapidly fairly large infeasibilities may be acceptable. As the change in objective in each iteration becomes smaller it will be necessary to solve the constraints more accurately so the "noise" in objective value from the inaccurate constraints will remain smaller than the real change. The noise is measured as the scalar product of the constraint residuals with the constraint marginals.

Sometimes it is necessary to revise the accuracy of the solution, for example because the algorithmic progress has slowed down or because the marginal of an inaccurate constraint has grown significantly after a basis change, e.g. when an inequality becomes binding. In these cases CONOPT will tighten the feasibility tolerance and perform one or more Newton iterations on the basic variables. This will usually be very quick and it happens silently. However, Newton's method may fail, for example in cases where the model is degenerate and Newton tries to move a basic variable outside a bound. In this case CONOPT uses some special iteration similar to those discussed in section [Finding a Feasible Solution: Phase 0](#) and they are labeled Phase 0.

These Phase 0 iterations may not converge, for example if the degeneracy is significant, if the model is very nonlinear locally, if the model has many product terms involving variables at zero, or if the model is poorly scaled and some constraints contain very large terms. If the iterations do not converge, CONOPT will issue the "Loss of feasibility ..." message, return to the real Phase 0 procedure, find a feasible solution with the smaller tolerance, and resume the optimization.

In rare cases you will see that CONOPT cannot find a feasible solution after the tolerances have been reduced, even though it has declared the model feasible at an earlier stage. We are working on reducing this problem. Until a final solution has been implemented you are encouraged to (1) consider if bounds on some degenerate variables can be removed, (2) look at scaling of constraints with large terms, and (3) experiment with the two feasibility tolerances, `rtnwma` and `rtnwmi` (see [Appendix B](#)), if this happens with your model.

5.11.8.13.4 Stalling CONOPT will usually make steady progress towards the final solution. A degeneracy breaking strategy and the monotonicity of the objective function in other iterations should ensure that CONOPT cannot cycle. Unfortunately, there are a few places in the code where the objective function may move in the wrong direction and CONOPT may in fact cycle or move very slowly.

The objective value used to compare two points, in the following called the adjusted objective value, is computed as the true objective plus a noise adjustment term equal to the scalar product of the residuals with the marginals (see section [Loss of Feasibility](#) where this noise term also is used). The noise adjustment term is very useful in allowing CONOPT to work smoothly with fairly inaccurate intermediate solutions. However, there is a disadvantage: the noise adjustment term can change even though the point itself does not change, namely when the marginals change in connection with a basis change. The adjusted objective is therefore not always monotone. When CONOPT loses feasibility and returns to Phase 0 there is an even larger chance of non-monotone behavior.

To avoid infinite loops and to allow the modeler to stop in cases with very slow progress CONOPT has an anti-stalling option. An iteration is counted as a stalled iteration if it is not degenerate and (1) the adjusted objective is worse than the best adjusted objective seen so far, or (2) the step length was zero without being degenerate (see $OK = F$ in section [Linear and Nonlinear Mode: Phase 1 to 4](#)). CONOPT will stop if the number of consecutive stalled iterations (again not counting degenerate iterations) exceeds `lfstal` and `lfstal` is positive. The default value of `lfstal` is 100. The message will be:

```
** Feasible solution. The tolerances are minimal and
   there is no change in objective although the reduced
   gradient is greater than the tolerance.
```

Large models with very flat optima can sometimes be stopped prematurely due to stalling. If it is important to find a local optimum fairly accurately then you may have to increase the value of `lfstal`.

5.11.8.13.5 Overflow and NaN (Not A Number) Very large values or overflow can appear in a number of places. CONOPT cannot use these values in the optimization since the results would be unreliable or useless. CONOPT is therefore trying to detect these values and take appropriate action.

Even though most modern computers can work with numbers from $1.e-300$ to $1.e+300$ CONOPT considers all numbers that are larger than $1.e40$ or NaN to be 'bad' and useless. NaN means Not A Number and includes Infinity and Real Overflow.

Bad numbers can have two sources. They can come from the modeler expressions or they can be generated internally in CONOPT. The nonlinear constraints or the derivatives of these constraints may return very large values. If a constraint returns a bad number you will see a message like

```
** A function value is very large or NaN (Not a Number).
   Add bound to ensure that the function values are defined and bounded.
```

and if a derivatives returns a bad number the message will be something like

```
** A derivative is very large or NaN (Not a Number).
   Add bound to ensure that the derivatives are defined and bounded.
```

The modeler must in both cases adjust the model to prevent that CONOPT receives these bad numbers so CONOPT stops immediately.

Bad numbers can also in rare cases appear as a result of computations inside CONOPT. Since all primal variables and all derivatives are bounded the bad numbers can only appear as a result of operations involving the factorization of the basis matrix, including the dual variables. You will in this case see a message like

```

** Overflow or Nan (Not A Number) has been encountered indicating
numerical difficulties. Trying to repair by increasing the
absolute and relative pivot tolerances (Rtpiva and Rvpivr)
and allowing small values to be scaled up by decreasing
the minimum scale factor, Rtmins.

```

Since the source of the problem is the factorization of the basis CONOPT will adjust the tolerances that are used while computing this factorization. Essentially, we must avoid very small pivots and the pivoting tolerances are therefore increased. The source of very small pivots can also be constraints were all terms are very small so CONOPT will also change the minimum scaling factor to try to avoid this source. CONOPT will continue the optimization after changing the tolerances and if the problem appears again it will change the tolerances even more, but since there is a limit to how much they can be adjusted CONOPT may have to give up and it will happen with this message

```

** Overflow or Nan (Not A Number) continues to be encountered
after multiple attempt to repair by changed tolerances.
CONOPT will give up.

```

The termination message will in this case be

```

** Feasible solution. The solution process has been terminated
because intermediate results have become NaN (Not A Number).

```

or

```

** Feasible solution. The solution process has been terminated
because intermediate results have become NaN (Not A Number).

```

If you encounter messages with NaN it is always a problem with scaling or structure. The most likely source is constraints with only small terms. Try to avoid them by scaling the variables and constraints appropriately, or try to use option `rtmins`. Or make CONOPT ignore these constraints by using a larger absolute pivot tolerance, `rtpiva`.

Another source are structured models with long chains of relationships. These models will usually have lags or leads and neighboring variables are related with a factor different from one, i.e.

```

dyn(i).. x(i) =e= x(i-1)*1.5 + u(i);

```

or

```

dif(i).. 2*x(i) =e= x(i-1) + x(i+1) + u(i);

```

CONOPT will try to solve the constraints in the proper order to avoid exploding variables, but a larger relative pivot tolerance, `rtpivr`, may also help. If you have a dynamic model and the variables are supposed to grow rapidly over time then you may consider having a scale factor that also grows with time.

5.11.8.13.6 External Equations and Extrinsic Functions CONOPT can be used with external equations and extrinsic functions written in a programming language such as Fortran or C. Additional information is available in the GAMS User's Guide [External Equations](#) and [Extrinsic Functions](#).

Extrinsic functions can be debugged using the function suffixes **gradn** and **hessn** which use finite differences to approximate the gradient and Hessian using multiple function calls. For details check model **drivtst** in the GAMS Model Library. If external equations are present CONOPT will automatically turn the Function and Derivative Debugger on in the initial point to discover potential errors in the gradient calculation inside the external library. The debugger will not only check the gradients of the external library but even check the gradients calculated by GAMS. In rare cases the debugger may report problems in the regular algebra part of the model for which GAMS has calculated the gradients. These violations should be small and can be ignored. After verifying that the external part of the model has been programmed correctly you may turn debugging off again by setting **Lkdebg** to 0 in an options file.

The debugger has two types of check. The first type ensures that the external equations do not depend on other variables than the ones you have specified in the GAMS representation. Structural errors found by these checks are usually caused by programming mistakes and must be corrected. The second type of check verifies that the derivatives returned by the external equations and extrinsic functions are consistent with the rate of change in function values. A derivative is considered to be wrong if the value returned by the modeler deviates from the value computed using numerical differences by more than **rtmxj2** times the step used for the numerical difference (usually around $1.e-7$). This check is correct if second derivatives are less than **rtmxj2**. **rtmxj2** has a default value of $1.e4$. If your model has larger second derivatives you may increase it in order not to get wrong error messages.

The number of error messages from the Function and Derivative Debugger is limited by **lfderr** with a default value of 10.

See [Debugging options](#) for a list of options that control the debugger.

5.11.9 APPENDIX B - Options

The options that ordinary GAMS users can access are listed below. Options starting on R assume real values, options starting on LS assume logical values (TRUE, T, 1, or FALSE, F, or 0), and all other CR-Cells starting on L assume integer values. The logical option **dohess** is only used by the interface between GAMS and CONOPT.

5.11.9.1 Algorithmic options

Option	Description	Default
LF2DRV	Limit on errors in Directional Second Derivative evaluation.	10
LFDEGI	Limit on number of degenerate iterations before starting degeneracy breaking strategy.	10
LFEERR	Limit on number of function evaluation errors. Overwrites GAMS Domlim option	GAMS DomLim
LFHSOK	Limit on errors in Hessian evaluation.	10
LFITER	Maximum number of iterations. Overwrites GAMS Iterlim option.	GAMS IterLim
LFMXNS	Maximum number of new superbasic variables added in one iteration.	auto
LFNICR	Limit on number of iterations with slow progress (relative less than Rtoobjl).	20
LFNSUP	Maximum number of superbasic variables in the approximation to the Reduced Hessian.	auto

Option	Description	Default
LFSCAL	Rescaling frequency.	5
LFSTAL	Limit on the number of stalled iterations.	100
LFUSDF	Limit on the number of candidates for defined variable in one constraint	2
LMDEBG	Method used by the function and derivative debugger.	0
LMMXSF	Method used to determine the step in Phase 0.	0
LMMXST	Method used to determine the maximum step while tightening tolerances.	0
LMNDIA	Method for initializing the diagonal of the approximate Reduced Hessian	0
LMSCAL	Method used for scaling.	3
LMUSDF	Method used with defined variables	0
LS2NDI	Flag for approximating Hessian information for incoming superbasics.	0
LS2PTJ	Flag for use of perturbations to compute 2nd derivatives in SQP method.	1
LSANRM	Flag for turning Steepest Edge on.	0
LSCRSR	Flag for crashing an initial basis without fixed slacks	1
LSESLP	Flag for enabling SLP mode.	1
LSSEQP	Flag for enabling of SQP mode.	1
LSISMP	Flag for Ignoring Small Pivots in Triangular models	0
LSLACK	Flag for selecting initial basis as Crash-triangular variables plus slacks.	0
LSPOST	Pre-processor flag for identifying and using post-triangular equations.	1
LSPRET	Pre-processor flag for identifying and using pre-triangular equations.	1
LSSCAL	Flag for dynamic scaling.	1
LSSQRS	Flag for Square System. Alternative to defining modeltype=CNS in GAMS	0
LSTCRS	Flag for using the triangular crash method.	0
LSTRIA	Flag for triangular or recursive system of equations.	0
LSTRID	Flag for turning diagnostics on for the post-triangular equations.	0
LSUQDF	Flag for requiring defined variables to be unique	1
LSUSDF	Flag for forcing defined variables into the basis	1
PRDEF	Flag for printing the defined variables and their defining constraints.	0
PRPOST	Flag for printing the post-triangular part of the model	0
PRPRET	Flag for printing the pre-triangular part of the model	0
RTBND1	Bound filter tolerance for solution values close to a bound.	1.e-7
RTBNDDT	Bound tolerance for defining variables as fixed.	1.e-7
RTIPVA	Absolute Pivot Tolerance for building initial basis.	1.e-7
RTIPVR	Relative Pivot Tolerance for building initial basis	1.e-3
RTMAXJ	Upper bound on the value of a function value or Jacobian element.	1.e10

Option	Description	Default
RTMAXS	Upper bound on scale factors.	1.e9
RTMAXV	Upper bound on solution values and equation activity levels	1.e10
RTMINA	Zero filter for Jacobian elements and inversion results.	1.e-20
RTMINJ	Filter for small Jacobian elements to be ignored during scaling.	1.e-5
RTMINS	Lower bound for scale factors computed from values and 1st derivatives.	1
RTMNS2	Lower bound for scale factors based on large 2nd derivatives.	1.e-6
RTNWMA	Maximum feasibility tolerance (after scaling).	1.e-7
RTNWMI	Minimum feasibility tolerance (after scaling).	4.e-10
RTNWTR	Feasibility tolerance for triangular equations.	2.0e-8
RTOBJL	Limit for relative change in objective for well-behaved iterations.	3.0e-12
RTOBJR	Relative accuracy of the objective function.	3.0e-13
RTONED	Accuracy of One-dimensional search.	0.2
RTPIVA	Absolute pivot tolerance.	1.e-10
RTPIVR	Relative pivot tolerance during basis factorizations.	0.05
RTPIVT	Absolute pivot tolerance for nonlinear elements in pre-triangular equations.	1.e-5
RTPIVU	Relative pivot tolerance during basis updates.	0.05
RTREDG	Optimality tolerance for reduced gradient.	1.e-7
RVFILL	Fill in factor for basis factorization.	5
RVTIME	Time Limit. Overwrites the GAMS Reslim option.	GAMS ResLim

5.11.9.2 Debugging options

Option	Description	Default
LFDERR	Limit on number of error messages from function and derivative debugger.	10
LKDEBG	Flag for debugging of first derivatives	0
RTMXJ2	Upper bound on second order terms.	1.e4
RTZERN	Zero-Noise in external equations	0.0

5.11.9.3 Output options

Option	Description	Default
LFEMSG	Limit on number of error messages related to large function value and Jacobian elements.	10
LFILOG	Frequency for log-lines for non-SLP/SQP iterations.	auto
LFILOS	Frequency for log-lines for SLP or SQP iterations.	auto
LFTMSG	Limit on number of error messages related to infeasible pre-triangle.	25

5.11.9.4 Interface options

Option	Description	Default
cooptfile		
DO2DIR	Flag for computing and using directional 2nd derivatives.	auto
DOHESS	Flag for computing and using 2nd derivatives as Hessian of Lagrangian.	auto
heaplimit	Maximum Heap size in MB allowed	Infinite
pretri2log	Send messages about the pre-triangular analyser to the log	0
RVHESS	Memory factor for Hessian generation: Skip if #Hessian elements > #Jacobian elements*Rvhess, 0 means unlimited.	10

cooptfile (*string*): [↩](#)

DO2DIR (*boolean*): Flag for computing and using directional 2nd derivatives. [↩](#)

If turned on, make directional second derivatives (Hessian matrix times directional vector) available to CONOPT. The default is on, but it will be turned off if the model has external equations (defined with =X=) and the user has not provided directional second derivatives. If both the Hessian of the Lagrangian (see [DOHESS](#)) and directional second derivatives are available then CONOPT will use both: directional second derivatives are used when the expected number of iterations in the SQP sub-solver is low and the Hessian is used when the expected number of iterations is large.

Default: **auto**

DOHESS (*boolean*): Flag for computing and using 2nd derivatives as Hessian of Lagrangian. [↩](#)

If turned on, compute the structure of the Hessian of the Lagrangian and make it available to CONOPT. The default is usually on, but it will be turned off if the model has external equations (defined with =X=) or if the Hessian becomes too dense. See also [DO2DIR](#) and [RVHESS](#).

Default: **auto**

heaplimit (*real*): Maximum Heap size in MB allowed [↩](#)

Default: **Infinite**

LF2DRV (*integer*): Limit on errors in Directional Second Derivative evaluation. [↩](#)

If the evaluation of Directional Second Derivatives (Hessian information in a particular direction) has failed more than Lf2drv times CONOPT will not attempt to evaluate them any more and will switch to methods that do not use Directional Second Derivatives. Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like power(x,1.5) at x=0.

Default: **10**

LFDEGI (*integer*): Limit on number of degenerate iterations before starting degeneracy breaking strategy. [↩](#)

The default CONOPT pivoting strategy has focus on numerical stability, but it can potentially cycle. When the number of consecutive degenerate iterations exceeds LFDEGI CONOPT will switch to a pivoting strategy that is guaranteed to break degeneracy but with slightly weaker numerical properties.

Default: 10

LFDERR (*integer*): Limit on number of error messages from function and derivative debugger. ↩

The function and derivative debugger (see [LKDEBG](#)) may find a very large number of errors, all derived from the same source. To avoid very large amounts of output CONOPT will stop the debugger after LFDERR error have been found.

Range: $[1, \infty]$

Default: 10

LFEERR (*integer*): Limit on number of function evaluation errors. Overwrites GAMS Domlim option ↩

Synonym: domlim

Function values and their derivatives are assumed to be defined in all points that satisfy the bounds of the model. If the function value or a derivative is not defined in a point CONOPT will try to recover by going back to a previous safe point (if one exists), but it will not do it more than at most Lfeerr times. If CONOPT is stopped by functions or derivatives not being defined it will return with a intermediate infeasible or intermediate non-optimal model status.

Default: GAMS DomLim

LFEMSG (*integer*): Limit on number of error messages related to large function value and Jacobian elements. ↩

Very large function value or derivatives (Jacobian elements) in a model will lead to numerical difficulties and most likely to inaccurate primal and/or dual solutions. CONOPT is therefore imposing an upper bound on the value of all function value and derivatives. This bound is 1.e30 for scaled models and [RTMAXJ](#) for unscaled models. If the bound is violated CONOPT will return with an intermediate infeasible or intermediate non-optimal solution and it will issue error messages for all the violating function value and Jacobian elements, up to a limit of Lfemsg error messages.

Range: $[1, \infty]$

Default: 10

LFHSOK (*integer*): Limit on errors in Hessian evaluation. ↩

If the evaluation of Hessian information has failed more than Lfhsok times CONOPT will not attempt to evaluate it any more and will switch to methods that do not use the Hessian. Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like $\text{power}(x, 1.5)$ at $x=0$.

Default: 10

LFILog (*integer*): Frequency for log-lines for non-SLP/SQP iterations. ↩

Lflog and Lflos can be used to control the amount of iteration send to the log file. The non-SLP/SQP iterations, i.e. iterations in phase 0, 1, and 3, are usually fast and writing a log line for each iteration may be too much, especially for smaller models. The default value for the log frequency for these iterations is therefore set to 10 for small models, 5 for models with more than 500 constraints or 1000 variables and 1 for models with more than 2000 constraints or 3000 variables.

Range: $[1, \infty]$

Default: `auto`

LFILOS (*integer*): Frequency for log-lines for SLP or SQP iterations. [↔](#)

Lflog and Lflos can be used to control the amount of iteration send to the log file. Iterations using the SLP and/or SQP sub-solver, i.e. iterations in phase 2 and 4, may involve several inner iterations and the work per iteration is therefore larger than for the non-SLP/SQP iterations and it may be relevant to write log lines more frequently. The default value for the log frequency is therefore 5 for small models and 1 for models with more than 500 constraints or 1000 variables.

Range: $[1, \infty]$

Default: `auto`

LFITER (*integer*): Maximum number of iterations. Overwrites GAMS Iterlim option. [↔](#)

Synonym: `iterlim`

The iteration limit can be used to prevent models from spending too many resources. You should note that the cost of the different types of CONOPT iterations (phase 0 to 4) can be very different so the time limit (GAMS Reslim or option [RVTIME](#)) is often a better stopping criterion. However, the iteration limit is better for reproducing solution behavior across machines.

Default: `GAMS IterLim`

LFMXNS (*integer*): Maximum number of new superbasic variables added in one iteration. [↔](#)

When there has been a sufficient reduction in the reduced gradient in one subspace new non-basics can be selected to enter the superbasis. The ones with largest reduced gradient of proper sign are selected, up to a limit. If Lfmnxns is positive then the limit is $\min(500, \text{Lfmnxns})$. If Lfmnxns is zero (the default) then the limit is selected dynamically by CONOPT depending on model characteristics.

Default: `auto`

LFNICR (*integer*): Limit on number of iterations with slow progress (relative less than `Rtobjl`). [↔](#)

The optimization is stopped if the relative change in objective is less than [RTOBJL](#) for Lfnicr consecutive well-behaved iterations.

Range: $[2, \infty]$

Default: 20

LFNSUP (*integer*): Maximum number of superbasic variables in the approximation to the Reduced Hessian. [↔](#)

CONOPT uses and stores a dense lower-triangular matrix as an approximation to the Reduced Hessian. The rows and columns correspond to the superbasic variable. This matrix can use a large amount of memory and computations involving the matrix can be time consuming so CONOPT imposes a limit on the size. The limit is LFNSUP if LFNSUP is defined by the modeler and otherwise a value determined from the overall size of the model. If the number of superbasics exceeds the limit, CONOPT will switch to a method based on a combination of SQP and Conjugate Gradient iterations assuming some kind of second order information is available. If no second order information is available CONOPT will use a quasi-Newton method on a subset of the superbasic variables and rotate the subset as the reduced gradient becomes small.

Range: $[5, \infty]$

Default: `auto`

LFSCAL (*integer*): Rescaling frequency. [↔](#)

The row and column scales are recalculated at least every Lfscal new point (degenerate iterations do not count), or more frequently if conditions require it.

Range: $[1, \infty]$

Default: 5

LFSTAL (*integer*): Limit on the number of stalled iterations. [↔](#)

An iteration is considered a stalled iteration if there is no change in objective because the linesearch is limited by nonlinearities or numerical difficulties. Stalled iterations will have Step = 0 and F in the OK column of the log file. After a stalled iteration CONOPT will usually try various heuristics to get a better basis and a better search direction. However, the heuristics may not work as intended or they may even return to the original bad basis, so to prevent cycling CONOPT stops after Lfstal stalled iterations and returns an Intermediate Infeasible or Intermediate Nonoptimal solution.

Range: $[2, \infty]$

Default: 100

LFTMSG (*integer*): Limit on number of error messages related to infeasible pre-triangle. [↔](#)

If the pre-processor determines that the model is infeasible it tries to define a minimal set of variables and constraints that define the infeasibility. If this set is larger than LFTMSG elements the report is considered difficult to use and it is skipped.

Default: 25

LFUSDF (*integer*): Limit on the number of candidates for defined variable in one constraint [↔](#)

When there are more than one candidate to be selected as a defined variable in a constraint CONOPT tries to select the most appropriate in order to select as many defined variables as possible. However, to avoid too much arbitrariness this is only attempted if there are not more than Lfusdf candidates.

Default: 2

LKDEBG (*integer*): Flag for debugging of first derivatives [↔](#)

Lkdebug controls how often the derivatives are tested. Debugging of derivatives is only relevant for user-written functions in external equations defined with `=X=`. The amount of debugging is controlled by **LMDEBG**. See [RTMXJ2](#) for a definition of when derivatives are considered wrong.

Default: 0

value	meaning
-1	The derivatives are tested in the initial point only.
0	No debugging
+n	The derivatives are tested in all iterations that can be divided by Lkdebg, provided the derivatives are computed in this iteration. (During phase 0, 1, and 3 derivatives are only computed when it appears to be necessary.)

LMDEBG (*integer*): Method used by the function and derivative debugger. [↔](#)

The function and derivative debugger (turned on with [LKDEBG](#)) can perform a fairly cheap test or a more extensive test, controlled by LMDEBG. See [RTMXJ2](#) for a definition of when derivatives are considered wrong. All tests are performed in the current point found by the optimization algorithm.

Default: 0

value	meaning
0	Perform tests for sparsity pattern and tests that the numerical values of the derivatives appear to be correct. This is the default.
1	As 0 plus make extensive test to determine if the functions and their derivatives are continuous around the current point. These tests are much more expensive and should only be used if the cheap test does not find an error but one is expected to exist.

LMMXSF (*integer*): Method used to determine the step in Phase 0. [↔](#)

The steplength used by the Newton process in phase 0 is computed by one of two alternative methods controlled by LMMXSF:

Default: 0

value	meaning
0	The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this default method.
1	A method based on bending (projecting the target values of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum. Linear constraints that initially are feasible may become infeasible due to bending. The method does not use anti-degeneracy. This will be taken care of by removing difficult constraints from the Newton Process at regular intervals. The bending method can sometimes be useful for CNS models that stop when a variable exceeds its bound in an intermediate point even though the final solution is known to be inside the bounds.

LMMXST (*integer*): Method used to determine the maximum step while tightening tolerances. [↔](#)

The steplength used by the Newton process when tightening tolerances is computed by one of two alternative methods controlled by LMMXST:

Default: 0

value	meaning
0	The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this default method.
1	A method based on bending (projecting the target value of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum.

LMNDIA (*integer*): Method for initializing the diagonal of the approximate Reduced Hessian $\leftrightarrow$

Each time a nonbasic variable is made superbasic a new row and column is added to the approximate Reduced Hessian. The off-diagonal elements are set to zero and the diagonal to a value controlled by LMNDIA:

Default: 0

value	meaning
0	The new diagonal element is set to the geometric mean of the existing diagonal elements. This gives the new diagonal element an intermediate value and new superbasic variables are therefore not given any special treatment. The initial steps should be of good size, but build-up of second order information in the new sub-space may be slower. The larger diagonal element may also in bad cases cause premature convergence.
1	The new diagonal elements is set to the minimum of the existing diagonal elements. This makes the new diagonal element small and the importance of the new superbasic variable will therefore be high. The initial steps can be rather small, but better second order information in the new sub-space should be build up faster.

LMSCAL (*integer*): Method used for scaling. $\leftrightarrow$

CONOPT will by default use scaling of the equations and variables of the model to improve the numerical behavior of the solution algorithm and the accuracy of the final solution, see [LSSCAL](#) and [LMSCAL](#). The objective of the scaling process is to reduce the values of all large primal and dual variables as well as the values of all large first derivatives so they become closer to 1. Small values are usually not scaled up, see [RTMAXS](#) and [RTMINS](#). Scaling method 3 is recommended. The others are only kept for backward compatibility.

Default: 3

value	meaning
0	Scaling is based on repeatedly dividing the rows and columns by the geometric means of the largest and smallest elements in each row and column. Very small elements less than RTMINJ are considered equal to RTMINJ.
1	Similar to 3 below, but the projection on the interval [Rtmins,Rtmaxs] is applied at a different stage. With method 1, $\text{abs}(X) \cdot \text{abs}(\text{Jac})$ with small X and very large Jac is scaled very aggressively with a factor $\text{abs}(\text{Jac})$. With method 3, the scale factor is $\text{abs}(X) \cdot \text{abs}(\text{Jac})$. The difference is seen in models with terms like $\text{Sqrt}(X)$ close to $X = 0$.
2	As 1 but the terms are computed based on a moving average of the squares X and Jac. The purpose of the moving average is to keep the scale factor more stable. This is often an advantage, but for models with very large terms (large variables and in particular large derivatives) in the initial point the averaging process may not have enough time to bring the scale factors into the right region.

value	meaning
3	Rows are first scaled by dividing by the largest term in the row, then columns are scaled by dividing by the maximum of the largest term and the value of the variable. A term is here defined as $\text{abs}(X) * \text{abs}(\text{Jac})$ where X is the value of the variable and Jac is the value of the derivative (Jacobian element). The scale factors are then projected on the interval between Rtmins and Rtmaxs .

LMUSDF (*integer*): Method used with defined variables [↔](#)

When defined variables are identified (see [LSUSDF](#)) they can be used in two ways, controlled by LMUSDF:

Default: 0

value	meaning
0	Defined variables are only used in the initial point and for the initial basis (default).
1	Defined variables are kept basic and the defining constraints are used to recursively assign values to the defined variables in all trial points.

LS2NDI (*boolean*): Flag for approximating Hessian information for incoming superbasics. [↔](#)

If `Ls2ndi` is turned on (1) CONOPT will try to estimate second order Hessian information for incoming superbasic variables based on directional second derivatives. This is more costly than the standard method described under [LMNDIA](#).

Default: 0

LS2PTJ (*boolean*): Flag for use of perturbations to compute 2nd derivatives in SQP method. [↔](#)

If on (1) CONOPT may use perturbations of the Jacobian to compute directional 2nd derivatives if they are not provided with other cheaper and more accurate methods. With GAMS it is only relevant for models with functions defined in external function libraries or models with external equations defined with the `=X=` equation type.

Default: 1

LSANRM (*boolean*): Flag for turning Steepest Edge on. [↔](#)

Flag used to turn steepest edge pricing on (1) or off (0). Steepest edge pricing makes the individual iterations more expensive but it may decrease their number. Only experimentation can show if it is worth while.

Default: 0

LSCRSH (*boolean*): Flag for crashing an initial basis without fixed slacks [↔](#)

When turned on (1) CONOPT will try to crash a basis without fixed slacks in the basis. Fixed slacks are only included in a last round to fill linearly dependent rows. When turned off, large infeasible slacks will be included in the initial basis with preference for variables and slacks far from bound.

Default: 1

LSESLP (*boolean*): Flag for enabling SLP mode. [↔](#)

If Lseslp is on (the default) then the SLP (sequential linear programming) sub-solver can be used, otherwise it is turned off.

Default: 1

LSESQP (*boolean*): Flag for enabling of SQP mode. [↔](#)

If Lsesqp is on (the default) then the SQP (sequential quadratic programming) sub-solver can be used, otherwise it is turned off.

Default: 1

LSISMP (*boolean*): Flag for Ignoring Small Pivots in Triangular models [↔](#)

Ignore SMALL Pivots. When turned on CONOPT will ignore the non-uniqueness from small pivots during a triangular solve (see [LSTRIA](#)). Note, that the non-uniqueness may propagate to later equations, but we cannot check for it in nonlinear equations.

Default: 0

LSLACK (*boolean*): Flag for selecting initial basis as Crash-triangular variables plus slacks. [↔](#)

When turned on together with [LSTCRS](#) CONOPT will use the triangular crash procedure and select the initial basis as the crash-triangular variables plus slacks in all remaining rows.

Default: 0

LSPOST (*boolean*): Pre-processor flag for identifying and using post-triangular equations. [↔](#)

When turned on (the default) CONOPT will try to identify post-triangular equations. Otherwise this phase is ignored.

Default: 1

LSPRET (*boolean*): Pre-processor flag for identifying and using pre-triangular equations. [↔](#)

When turned on (the default) CONOPT will try to identify pre-triangular equations. Otherwise this phase is ignored.

Default: 1

LSSCAL (*boolean*): Flag for dynamic scaling. [↔](#)

When Lsscal is on (the default) CONOPT will use dynamic scaling of equations and variables. See also [LMSCAL](#).

Default: 1

LSSQRS (*boolean*): Flag for Square System. Alternative to defining modeltype=CNS in GAMS [↔](#)

When turned on the modeler declares that this is a square system, i.e. the number of non-fixed variables must be equal to the number of constraints, no bounds must be active in the final solution, and the basis selected from the non-fixed variables must always be nonsingular.

Default: 0

LSTCRS (*boolean*): Flag for using the triangular crash method. [↔](#)

When turned on CONOPT will try to crash a triangular basis using ideas by Gould and Reid. The procedure relies on identifying and using good initial values provided by the modeler and only assigning values to variables that are not initialized. Should only be used when several important variables have been given reasonable initial values. The sum of infeasibilities may for some models grow during the crash procedure, so modelers are advised that the option should be used with caution. The option will be ignored if defined variables are forced into the bases [Lsusdf](#).

Default: 0

LSTRIA (*boolean*): Flag for triangular or recursive system of equations. [↔](#)

If turned on the equations must form a recursive system. Equations that depend on known variables are allowed as long as they are consistent, e.g. $x = 1$ and $2*x = 2$. If the equations are not recursive the model is considered infeasible, and the equations with minimum row count are flagged together with the columns they intersect. See also [LSISMP](#).

Default: 0

LSTRID (*boolean*): Flag for turning diagnostics on for the post-triangular equations. [↔](#)

If turned on certain diagnostic messages related to the post-triangular equations will be printed. The messages are mainly related to unusual modeling constructs where linear variables for example only appear in the objective or where certain constraints are guaranteed redundant.

Default: 0

LSUQDF (*boolean*): Flag for requiring defined variables to be unique [↔](#)

When turned on (1) CONOPT will not allow defined variables unless they are unique. We exclude a variable if it can be defined from more than one equation, and we exclude equations if they can be used to define more than one variable.

Default: 1

LSUSDF (*boolean*): Flag for forcing defined variables into the basis [↔](#)

When turned on (1) CONOPT will identify defined variables from constraints of the type $x(i) = f(x)$ where $x(i)$ is free or implied free. The largest number of defined variables possible will be made basic and will be assigned initial values that are consistent with their defining constraint. When turned off (0) defined variables and their defining constraints are treated like all other variables and constraints. When turned on the triangular crash ([LSTCRS](#)) will not be used

Default: 1

PRDEF (*boolean*): Flag for printing the defined variables and their defining constraints. [↔](#)

When turned on (1) CONOPT will print a list of the defined variables and their defining constraints in the order in which they can be evaluated.

Default: 0

pretri2log (*boolean*): Send messages about the pre-triangular analyser to the log [↔](#)

Default: 0

PRPOST (*boolean*): Flag for printing the post-triangular part of the model [↔](#)

When turned on (1) CONOPT will print a list of the post-triangular constraints and the variables they are solved for in the order in which they can be evaluated.

Default: 0

PRPRET (*boolean*): Flag for printing the pre-triangular part of the model [↔](#)

When turned on (1) CONOPT will print a list of the pre-triangular constraints and the variables they are solved for, including the solution values, in the order in which they are solved.

Default: 0

RTBND1 (*real*): Bound filter tolerance for solution values close to a bound. [↔](#)

A variable is considered to be at a bound if its distance from the bound is less than $Rtbnd1 \cdot \text{Max}(1, \text{ABS}(\text{Bound}))$. If you need a very small value then your model is probably poorly scaled.

Range: $[3.e-13, 1.e-5]$

Default: $1.e-7$

RTBNDT (*real*): Bound tolerance for defining variables as fixed. [↔](#)

A variable is considered fixed if the distance between the bounds is less than $Rtbndt \cdot \text{Max}(1, \text{Abs}(\text{Bound}))$. The tolerance is also used on implied bounds (from converted inequalities) and these implied bounds may be infeasible up to $Rtbndt$.

Range: $[3.e-13, 1.e-5]$

Default: $1.e-7$

RTIPVA (*real*): Absolute Pivot Tolerance for building initial basis. [↔](#)

Absolute pivot tolerance used during the search for a first logically non-singular basis. The default is fairly large to encourage a better conditioned initial basis.

Range: $[3.e-13, 1.e-3]$

Default: $1.e-7$

RTIPVR (*real*): Relative Pivot Tolerance for building initial basis [↔](#)

Relative pivot tolerance used during the search for a first logically non-singular basis.

Range: $[1.e-4, 0.9]$

Default: $1.e-3$

RTMAXJ (*real*): Upper bound on the value of a function value or Jacobian element. [↔](#)

Very large values of variables, function value, and derivatives and in particular large variations in the absolute value of the variables, functions, and derivatives makes the model harder to solve and poses problems for both feasibility and optimality tests. CONOPT will usually try to scale the model (see [LSSCAL](#)) to remove these problems. However, scaling can also make important aspects of a model appear un-important and there is therefore a limit to how aggressively we can scale a model (see [RTMAXS](#) and [RTMINS](#)). To avoid serious scaling problems CONOPT poses upper bounds on all variables (see [RTMAXV](#)) and all function value and derivatives, [RTMAXJ](#).

Range: $[1.e4, 1.e30]$

Default: $1.e10$

RTMAXS (*real*): Upper bound on scale factors. [↔](#)

Scale factors are projected on the interval from Rtmns to Rtmxs. Is used to prevent very large or very small scale factors due to pathological types of constraints. RTMAXS is silently increased to $\max(\text{RTMAXV}, \text{RTMAXS})/100$ if RTMAXV or RTMAXJ have large non-default values.

Range: $[1, 1.e20]$

Default: $1.e9$

RTMAXV (*real*): Upper bound on solution values and equation activity levels [↔](#)

See [RTMAXJ](#) for a discussion of why CONOPT poses upper bounds on variables and derivatives. If the value of a variable, including the objective function value, exceeds RTMAXV then the model is considered to be unbounded and the optimization process returns the solution with the large variable flagged as unbounded.

Range: $[1.e5, 1.e30]$

Default: $1.e10$

RTMINA (*real*): Zero filter for Jacobian elements and inversion results. [↔](#)

Contains the smallest absolute value that an intermediate result can have. If it is smaller, it is set to zero. It must be smaller than [RTPIVA](#)/10.

Range: $[1.e-30, \infty]$

Default: $1.e-20$

RTMINJ (*real*): Filter for small Jacobian elements to be ignored during scaling. [↔](#)

A Jacobian element is considered insignificant if it is less than Rtmnj. The value is used to select which small values are scaled up during scaling of the Jacobian.

Range: $[1.e-7, 1.e-3]$

Default: $1.e-5$

RTMINS (*real*): Lower bound for scale factors computed from values and 1st derivatives. [↔](#)

Scale factors used to scale variables and equations are projected on the range Rtmns to Rtmxs. The limits are used to prevent very large or very small scale factors due to pathological types of constraints. The default value for Rtmns is 1 which means that small values are not scaled up. If you need to scale small value up towards 1 then you must define a value of Rtmns < 1 .

Range: $[1.e-10, 1]$

Default: 1

RTMNS2 (*real*): Lower bound for scale factors based on large 2nd derivatives. [↔](#)

Scaling of the model is in most cases based on the values of the variables and the first derivatives. However, if the scaled variables and derivatives are reasonable but there are large values in the Hessian of the Lagrangian (the matrix of 2nd derivatives) then the lower bound on the scale factor can be made smaller than Rtmns. CONOPT will try to scale variables with large 2nd derivatives by one over the square root of the diagonal elements of the Hessian. However, the revised scale factors cannot be less than Rtmns2.

Range: $[1.e-9, 1]$

Default: $1.e-6$

RTMXJ2 (*real*): Upper bound on second order terms. [↔](#)

The function and derivative debugger (see [LKDEBG](#)) tests if derivatives computed using the modelers routine are sufficiently close to the values computed using finite differences. The term for the acceptable difference includes a second order term and uses RTMXJ2 as an upper bound on second order derivatives in the model. Larger RTMXJ2 values will allow larger deviations between the user-defined derivatives and the numerically computed derivatives.

Range: $[1, \infty]$

Default: 1.e4

RTNWMA (*real*): Maximum feasibility tolerance (after scaling). [↔](#)

The feasibility tolerance used by CONOPT is dynamic. As long as we are far from the optimal solution and make large steps it is not necessary to compute intermediate solutions very accurately. When we approach the optimum and make smaller steps we need more accuracy. RTNWMA is the upper bound on the dynamic feasibility tolerance and [RTNWMI](#) is the lower bound.

Range: $[1.e-10, 1.e-3]$

Default: 1.e-7

RTNWMI (*real*): Minimum feasibility tolerance (after scaling). [↔](#)

See [RTNWMA](#) for a discussion of the dynamic feasibility tolerances used by CONOPT.

Range: $[4.e-11, 1.e-5]$

Default: 4.e-10

RTNWTR (*real*): Feasibility tolerance for triangular equations. [↔](#)

Triangular equations are usually solved to an accuracy of [RTNWMI](#). However, if a variable reaches a bound or a constraint only has pre-determined variables then the feasibility tolerance can be relaxed to Rtnwtr.

Range: $[3.e-13, 1.e-4]$

Default: 2.0e-8

RTOBJL (*real*): Limit for relative change in objective for well-behaved iterations. [↔](#)

The change in objective in a well-behaved iteration is considered small and the iteration counts as slow progress if the change is less than $Rtobjl * \text{Max}(1, \text{Abs}(\text{Objective}))$. See also [LFNICR](#).

Range: $[3.0e-13, 1.0e-5]$

Default: 3.0e-12

RTOBJR (*real*): Relative accuracy of the objective function. [↔](#)

It is assumed that the objective function can be computed to an accuracy of $Rtobjr * \text{max}(1, \text{abs}(\text{Objective}))$. Smaller changes in objective are considered to be caused by round-off errors.

Range: $[3.0e-14, 10.e-6]$

Default: 3.0e-13

RTONED (*real*): Accuracy of One-dimensional search. [↔](#)

The onedimensional search is stopped if the expected decrease in then objective estimated from a quadratic approximation is less than Rtoned times the decrease so far in this onedimensional search.

Range: [0.05, 0.8]

Default: 0.2

RTPIVA (*real*): Absolute pivot tolerance. [↔](#)

During LU-factorization of the basis matrix a pivot element is considered large enough if its absolute value is larger than Rtpiva. There is also a relative test, see [RTPIVR](#).

Range: [2.2e-16, 1.e-7]

Default: 1.e-10

RTPIVR (*real*): Relative pivot tolerance during basis factorizations. [↔](#)

During LU-factorization of the basis matrix a pivot element is considered large enough relative to other elements in the column if its absolute value is at least Rtpivr * the largest absolute value in the column. Small values or Rtpivr will often give a sparser basis factorization at the expense of the numerical accuracy. The value used internally is therefore adjusted dynamically between the users value and 0.9, based on various statistics collected during the solution process. Certain models derived from finite element approximations of partial differential equations can give rise to poor numerical accuracy and a larger user-value of Rtpivr may help.

Range: [1.e-3, 0.9]

Default: 0.05

RTPIVT (*real*): Absolute pivot tolerance for nonlinear elements in pre-triangular equations. [↔](#)

The smallest pivot that can be used for nonlinear or variable Jacobian elements during the pre-triangular solve. The pivot tolerance for linear or constant Jacobian elements is Rtpiva. The value cannot be less than Rtpiva.

Range: [2.2e-16, 1.e-3]

Default: 1.e-5

RTPIVU (*real*): Relative pivot tolerance during basis updates. [↔](#)

During basischanges CONOPT attempts to use cheap updates of the LU-factors of the basis. A pivot is considered large enough relative to the alternatives in the column if its absolute value is at least Rtpivu * the other element. Smaller values of Rtpivu will allow sparser basis updates but may cause accumulation of larger numerical errors.

Range: [1.e-3, 0.9]

Default: 0.05

RTREDG (*real*): Optimality tolerance for reduced gradient. [↔](#)

The reduced gradient is considered zero and the solution optimal if the largest superbasic component of the reduced gradient is less than `Rtredg`.

Range: `[3.e-13, 1]`

Default: `1.e-7`

RTZERN (*real*): Zero-Noise in external equations [↔](#)

By default CONOPT will debug the derivatives returned from External functions in GAMS in the initial point (see [LKDEBG](#)). If external functions have constant derivatives then the constant terms are still part of the external function and this can give rise to small inaccuracies in the contribution of the constant derivatives to the function value. This noise can cause the debugger to incorrectly state that a the external equation depend on the variable with the constant derivative. A larger value of `Rtzern` should remove the error.

Range: `[0.0, 1]`

Default: `0.0`

RVFILL (*real*): Fill in factor for basis factorization. [↔](#)

`Rvfill` is used in the initial allocation of memory for the factorization of the basis. The fill-in (number of new nonzeros) is assumed to be `Rvfill-1` times the initial number of nonzeros in the basis. The default is 5 but you may experiment with a smaller value (down to 1.0) for models that use too much memory to get started. If `Rvfill` is small you may get slower execution due to increased memory movement. And you may still run out of memory later in the optimization.

Range: `[1.00, 20]`

Default: `5`

RVHESS (*real*): Memory factor for Hessian generation: Skip if `#Hessian elements > #Jacobian elements*Rvhess`, 0 means unlimited. [↔](#)

The Hessian of the Lagrangian is considered too dense and is not passed on to CONOPT if the number of nonzero elements in the Hessian of the Lagrangian is greater than the number of nonlinear Jacobian elements multiplied by `Rvhess`. The assumption is that a very dense Hessian is expensive both to compute and use. If `Rvhess = 0.0` then there is no limit on the number of Hessian elements.

Default: `10`

RVTIME (*real*): Time Limit. Overwrites the GAMS `Reslim` option. [↔](#)

Synonym: `reslim`

The upper bound on the total number of seconds that can be used in the execution phase. There are only tests for time limit once per iteration. The default value is 10000. `Rvtime` is overwritten by `Reslim` when called from GAMS. `Rvtime` is defined in `ProbSize` and/or `UpdtSize` when used as a subroutine library.

Default: `GAMS ResLim`

5.12 CONOPT4

Arne Drud, ARKI Consulting and Development A/S, Bagsvaerd, Denmark

5.12.1 Introduction

CONOPT4 is an NLP solver derived from [CONOPT3](#) but with many changes. This initial note will describe some of the more important changes from [CONOPT3](#) to CONOPT4 and some of the new options that control these changes. Selected parts of the log-file are also shown and explained. The note is fairly technical and the casual user does not have to understand the details.

More self-contained documentation for CONOPT4 without numerous references to [CONOPT3](#) will appear later.

5.12.2 When should you use CONOPT4?

[CONOPT3](#) is a mature solver with a lot of build-in heuristics developed over years of experimentation and [CONOPT3](#) works well for a large class of models. Initially, CONOPT4 is being developed and tuned for models where [CONOPT3](#) has problems or where small adjustments have given a better solver. Our initial recommendations are:

- CONOPT4 should be tried on models that take more than a few minutes to solve. [CONOPT3](#) is probably your best guess for small and medium sized models, i.e. models with less than 1,000 to 10,000 variables and constraints.
 - CONOPT4 should be tried for large CNS models, i.e. models with more than 100,000 variables and constraints.
 - CONOPT4 should be tried for models where [CONOPT3](#) runs out of memory. However, note that models of this size under all circumstances are very large and good behavior cannot be guaranteed.
 - CONOPT4 should be tried on models where [CONOPT3](#) ends in a locally infeasible solution. CONOPT4 has several new components that avoid obviously infeasible areas and let CONOPT4 move away from saddle points.
 - CONOPT4 should be tried on models where [CONOPT3](#) finds a large number of definitional constraints.
-

5.12.3 Memory Management

CONOPT3 has a limit on the amount of memory that can be used of 2 or 3 GBytes for 32-bit systems and 8 GBytes for 64-bit systems. The way memory is allocated and used has been completely rewritten and there is no longer a logical limit in CONOPT4. 32-bit systems will still have a 2 or 3 GBytes limit derived from the operating system, but 64-bit systems are now only limited by the amount of physical memory on the computer.

5.12.4 Revised Preprocessor

The preprocessor in CONOPT3 identifies pre- and post-triangular variables and constraints, and it handles these variables and constraints in a special way so some internal routines can run more efficiently. The triangular variables are for example always basic. CONOPT3 does not include these variables in tests for entering and leaving the basis. And triangular variables are processed before other variables in the inversion routine. Despite the special status of some variables and constraints, they are all part of the model to be solved.

CONOPT4 distinguished between a 'user model' as defined by the user via the GAMS language, and an 'internal model'. Pre-triangular variables and constraints are simply removed from the user model. Post-triangular variables and constraints are collapsed into a single condensed objective function. And definitional constraints are eliminated. After the internal model has been solved CONOPT4 translates the internal solution back into the solution for the user model and reports this solution to the user. Because CONOPT4 uses these two different models it is no longer possible to turn the preprocessor off.

In addition to the simple pre- and post-triangular variables and constraints from CONOPT3, the preprocessor in CONOPT4 looks at more possibilities for simplifying the model. Some of the new features are:

- Fixed variables are removed completely.
 - Constraints that represent simple inequalities are identified and changed into simple bounds on the variables and the constraints are removed.
 - Simple monotone constraints such as $\exp(x) =L= c1$ or $\log(y) =L= c2$ are converted into simple bounds on the variables and then removed.
 - Forcing constraints such as $x1 + x2 =L= 0$ with $x1.lo = 0$ and $x2.lo = 0$ are identified, the variables are fixed, and the constraints are removed. If a forcing constraint is identified then other constraints may become pre-triangular so they also can be removed.
 - Linear and monotone constraints are used to compute 'implied bounds' on many variables and these bounds can help CONOPT4 get a better starting point for finding an initial feasible solution.
 - Some non-monotone constraints such as $\text{sqr}(x1) + \text{sqr}(x2) =L= 1$ can also be used to derive implied bounds (here $-1 < x1 < +1$ and $-1 < x2 < +1$) that both can improve the starting point and can be used to determine that other terms are monotone.
 - Constraints with exactly two variables, e.g. simple linear identities such as $x1 =E= a*x2 + b$ or simple monotone identities such as $x3 =E= \exp(x4)$, are used to move bounds between the two variables and this may result in more variables being included in the post-triangle.
 - Linear constraints that are identical or proportional to others are identified and removed.
 - Pairs of constraints that define a lower and an upper bound on the same linear expression or proportional linear expressions, e.g. $1 =L= x1 + x2$ and $2*x1+2*x2 =L= 4$, are turned into a single ranged constraint implemented with a double-bounded slack variable.
 - Nonlinear constraints that become linear when the pre-triangular variables are fixed are recognized as being linear with the resulting simplifications.
-

Some of the new preprocessing steps are useful when solving sub-models in a Branch and Bound environment. A constraint like $x = M \cdot y$ where y is a binary variable fixed at either 0 or 1 is turned into a simple bound on x . And a constraint like $\text{sum}(i, x(i)) = \text{Cap} \cdot y$ (with $x.\text{lo}(i) = 0$) combined with y fixed at zero will force all $x(i)$ to zero.

The preprocessor also identifies constructs that are easy to make feasible. There are currently two types:

- **Penalty terms:** We define a penalty constraint as a constraint of the form $f(x_1, x_2, \dots) + p - n = 0$, where p and n are positive variables, and where p and n only appear in post-triangular constraints or in previously identified penalty constraint. For any feasible values of the x -variables it is easy to find values of p and n that makes the penalty constraint feasible: $p = \max(0, -f(x))$ and $n = \max(0, f(x))$. The definition is easily generalized to constraints where p and n have coefficients different from one and nonzero bounds; the essence is the presence of two linear unbounded terms of opposite sign.
- **Minimax terms:** We define a minimax group as a group of constraints of the form $\text{eq}(i) \dots f_i(x_1, x_2, \dots) = z$ where z is common to the group and otherwise only appear in post-triangular constraints, and z is unbounded from above. For any feasible value of the x -variables it is easy to find a value of z that makes the minimax group feasible: $z = \text{smin}(i: f_i(x))$. The definition is easily generalized to groups of constraints where z has coefficients different from one and where the direction of the inequality is reversed.

The preprocessor will also recognize definitional equations: constraints of the form $x = f(y)$, where x is a free variable or the bounds on x cannot be binding, are called definitional equations and x is called a defined variable. If there are many potential defined variable the preprocessor will select a recursive set and logically eliminate them from the internal model: The values of the defined variables are easily derived from the values of all other variables by evaluating the definitional equations in their recursive order, and these values are substituted into the remaining constraints before their residuals are computed. The matrix of derivatives of the remaining constraints is computed from the overall matrix of derivatives via an elimination of the triangular definitional equations.

The procedure used to recognize definitional equation is similar to the one used in [CONOPT3](#). However, the actual use of the definitional equations is quite different in CONOPT4. The definitional equations are eliminated from the internal model and they are not present in the internal operations used to solve this model. For some models this can make a big difference.

We will show a few examples of log files where the output from the preprocessor is shown. The first is from the **otpop.gms** model in the GAMS Library:

```

```

```
The user model has 104 variables and 77 constraints
with 285 Jacobian elements, 100 of which are nonlinear.
The Hessian of the Lagrangian has 17 elements on the diagonal,
33 elements below the diagonal, and 66 nonlinear variables.
```

```
Iter Phase  Ninf  Infeasibility  RGmax      NSB   Step  InItr  MX  OK
   0    0          4.0939901439E+03 (Input point)
```

```
The pre-triangular part of the model has 32 constraints and 43 variables.
The post-triangular part of the model has 9 constraints and variables.
There are 13 definitional constraints and defined variables.
```

Preprocessed model has 39 variables and 23 constraints
with 88 Jacobian elements, 22 of which are nonlinear.

Iter	Phase	Ninf	Infeasibility	RGmax	NSB	Step	InItr	MX	OK
			1.0510968588E+03						
			(Full preprocessed model)						
			4.5063072017E+01						
			(After scaling)						
			5.0023365462E+00						
			(After adjusting individual variables)						

The first few lines define the size of the user model. Usually there will also be information on the Hessian of the Lagrangian; these two lines are missing from models where the Hessian is not generated, usually because it is very large and dense (or because the generation has been turned off with the option `Flg.Hessian = false`).

After the description of the initial sum of infeasibilities there are three lines with statistics from the preprocessor. Note that the pre-triangular part of the model has more variables than constraints, in this case because there are fixed variables. The post-triangular part will always have the same number of constraints as variables, and the same is true for definitional constraints and defined variables.

After the statistics from the preprocessor the size of the resulting internal model is shown. There is no Hessian information; it is costly to derive the Hessian for the internal model and it will in most cases be very dense so all use of 2nd order information in the internal model is computed by mapping data to the user model and using the real Hessian.

The next lines show the change in the sum of infeasibilities during the initial stages. The first line is after the preprocessor has changed some variables and removed many constraints. The second line is after the internal model has been scaled. And last line is after some variables have been adjusted as described in the next section.

The second example is from the **prolog.gms** model in the GAMS Library:

Iter	Phase	Ninf	Infeasibility	RGmax	NSB	Step	InItr	MX	OK
0	0		1.2977431398E+03						
			(Input point)						
			The post-triangular part of the model has 1 constraints and variables.						
			There are 17 penalty and minimax constraints with 3 variables.						

Reduced model without penalty components has 17 variables and
5 constraints with 46 Jacobian elements, 0 of which are nonlinear.

Iter	Phase	Ninf	Infeasibility	RGmax	NSB	Step	InItr	MX	OK
			1.2960000000E+03						
			(Model without penalty constraints)						
			5.0625000000E+00						
			(After scaling)						
			0.0000000000E+00						
			(After adjusting individual variables)						

There are no pre-triangular variables and constraints and the pre-triangular line is therefore missing, just like the line describing definitional constraints. On the other hand, there is a line telling that the model has 17 penalty and minimax constraints involving a total of 3 variables.

The internal model that is generated is here without the penalty and minimax constraints. This particular sub-model and other internal sub-models are described in more detail later in this note.

5.12.5 Phase 0 - Finding an Initial Feasible Solution

Phase 0 is started with a new 'Adjust Initial Point' procedure that tries to minimize the sum of infeasibilities by changing individual variables one at a time. The procedure is very cheap since each change of a single variable only involve a small part of the overall model, and it will as a by-product produce a large part of a good initial basis and many constraints will become feasible. As the log file examples above shows, the procedure can in some cases reduce the sum of infeasibilities significantly.

Phase 0 in [CONOPT3](#) is based on Newton's method with a heuristic for taking some constraints out if they do not behave well for Newton. The method can be very fast if a good initial basis is found, but for larger models it can also use a large number of basis changes without any real improvement and can therefore be very slow. CONOPT4 has replaced the heuristic with a rigorous LP framework that iteratively finds a better basis for Newton's method. CONOPT4 can therefore be slower for very easy models but the variability in solution time is smaller and it should never be very slow.

The new Phase 0 procedure replaces the Triangular Crash procedure from [CONOPT3](#).

The following example shows the relevant part of the log file for GAMS Library model **otpop.gms**: gms (continued from above):

Iter	Phase	Ninf	Infeasibility	RGmax	NSB	Step	InItr	MX	OK
			1.0510968588E+03						
			(Full preprocessed model)						
			4.5063072017E+01						
			(After scaling)						
			5.0023365462E+00						
			(After adjusting individual variables)						
1	0	0	2.2657221820E+00			1.0E+00	3	T	T
2	0	0	1.8510537501E+00			1.0E+00	2	T	T
3	0	0	1.8243868306E+00			1.0E+00	1	T	T
4	0	0	1.8239239188E+00			1.0E+00	1	T	T
5	0	0	1.8239236521E+00			1.0E+00	1	T	T
** Feasible solution. Value of objective = 323.670194144									

The **InItr** column shows the number of LP-like inner iterations for each outer iteration and **Step = 1** indicates that the full solution from the LP was be used.

The next example is from GAMS Library model **mathopt3.gms**:

Iter	Phase	Ninf	Infeasibility	RGmax	NSB	Step	InItr	MX	OK
			1.7198687345E+03						
			(Full preprocessed model)						
			7.9643177481E+00						
			(After scaling)						
			1.2674164214E-01						
			(After adjusting individual variables)						
1	S0	0	2.6763223208E+00			1.2E-01	2	F	F
2	0	0	1.3292743354E+00			1.0E+00	2	T	T
3	S0	0	4.9371333807E+00			2.5E-01	1	F	F
4	S0	0	2.3899063615E+00			1.0E+00	2	T	T
5	S0	0	3.2207192474E+00			5.0E-01	1	F	F
6	0	0	3.2206913182E+00			6.2E-02	1	F	F
7	1	3	6.8573593504E-01	1.7E+00	1	1.2E+00	1	T	T

For some of the iterations Step is less than 1 indicating that the direction found by the inner linear model could not be used in full due to nonlinearities. Also note the lines with 'S0' in the Phase column. The S tells that the model was scaled before the iteration and the sum of infeasibilities was increased during this scaling procedure. The sum of infeasibilities is therefore not monotone decreasing even if each outer iteration does decrease them.

5.12.6 Transition between SLP and SQP

The transition from SLP to SQP and back again is in [CONOPT3](#) based on monitoring failure. The logic has been changed in CONOPT4 so transition is based on continuous measurements of curvature, both in the general constraints and in the objective function, combined with estimates of computational costs and progress for SLP and SQP.

The continuation of the log file for GAMS Library model otpop.gms shows some of this:

Iter	Phase	Ninf	Objective	RGmax	NSB	Step	InItr	MX	OK
6	3		2.3861517936E+02	3.6E+02	12	2.1E-01	7	F	T
7	3		1.4308470370E+02	1.1E+02	16	2.0E-01	9	F	T
8	3		9.4375606705E+01	1.5E+02	16	1.8E-01	5	F	F
9	3		2.4652509772E+01	7.4E+01	16	6.7E-01	2	F	T
10	4		2.4445151316E-02	3.3E+01	16	1.0E+00	6	F	T
11	4		5.0735392100E-06	4.4E+00	16	1.0E+00	5	F	T
12	4		1.0276261682E-09	1.9E-02	16	1.0E+00	3	F	T
13	4		1.4326828955E-13	2.8E-06	16	1.0E+00	1	F	T
14	4		1.4326828955E-13	4.0E-10	16				

**** Optimal solution. Reduced gradient less than tolerance.**

Iterations 6 to 9 are SLP iterations (Phase 3) and iterations 10 to 14 are SQP iterations (Phase 4). The SLP iterations have Step less than 1 due to nonlinear objective terms and CONOPT4 jumps directly from SLP to SQP. [CONOPT3](#) needed some steepest descend and some Quasi-Newton iterations as a transition, and although these iterations are fast, the transition could sometimes be slow.

5.12.7 Bad Iterations

Bad iterations (for both solvers flagged with “F” in the “OK” column of the log file) are an important problem for both [CONOPT3](#) and CONOPT4. They appear if the output from the SLP or SQP procedure is a search direction where CONOPT cannot move very far because it is difficult to make the nonlinear constraints feasible again. The efforts spend in solving the SLP or SQP procedure is therefore partially wasted. The problem is usually associated with a basis that is ill-conditioned or changes very fast.

[CONOPT3](#) has some heuristics for changing the basis in these cases. For models with many basic and superbasic variables this can be a slow and not very reliable procedure.

CONOPT4 uses a more rigorous procedure based on monitoring the size of some intermediate terms. It can be the size of elements of the tangent for basic variables relative to similar elements for superbasic variables. Or it can be intermediate results from the computation of the reduced costs. The monitoring procedure is cheap and it is used to maintain a well-conditioned basis throughout the optimization instead of waiting until something does not work well.

5.12.8 Saddle Points and Directions of Negative Curvature

CONOPT is based on moving in a direction derived from the gradient (or the reduced gradient for models with constraints). If the reduced gradient (projected on the bounds) is zero then the solution satisfies the first-order optimality conditions and it is standard procedure to stop. Unfortunately, this means that we can stop in a saddle-point.

It is not very common to move towards a saddle-point and get stuck in it. However, it is not uncommon that the initial point, provided by a user or by default, is a saddle point. A simple example is the

constraint $x*y =E= 1$ started with $x.l = y.l = 0$ that easily can end with a locally infeasible solution. Or minimize z , $z =E= x*y$ with the same starting point that could end locally optimal without moving even though better points exist in the neighborhood.

CONOPT4 has an added procedure that tries to find a direction of negative curvature that can move the solution point away from a saddle-point. The procedure is only called in points that satisfy the first order optimality conditions and it is therefore a cheap safeguard. The theory behind the method is developed for models without degeneracy and it works very well in practice for these models. Models with some kind of degeneracy (basic variables at bound or nonbasic variables with zero reduced cost) use the same procedure, but it is in this case only a heuristic that cannot be guaranteed to find a direction of negative curvature, even if one exists.

If you know that there are no directions of negative curvature you can turn the procedure off by setting the logical option `Flg_NegCurve` to false. If the model is known to be convex you can set the logical option `Flg_Convex` to true and it will also turn this procedure off. The saving is usually very small, except for models that solve in very few iterations and for model with a large number of superbasics.

There is no output in the log file for negative curvature. If a useful direction is found CONOPT4 will follow it and the optimization continues. Otherwise, the solution is declared locally optimal.

5.12.9 Use of Alternative Sub-Models

During the course of an optimization CONOPT4 can work with up to three different internal sub-models. These models are:

- Full Model: This model consists of the constraints in the user's model excluding all pre- and post-triangular constraints and with the definitional variables eliminated by their defining constraints.
- No-Penalty Model: This model consists of the Full Model excluding all penalty and mini-max constraints. This model does not have an objective function.
- Linear Feasibility Model: This model consists of the linear constraints of the Full Model. The Linear Feasibility model is either solved without an objective function or minimizing a quadratic distance measure; this is discussed below.

The pre-triangular variables are considered fixed and they do not appear in any of the sub-models. Their influence comes through their contribution to coefficients and constant terms. The post-triangular variables are considered intermediate variables in the definition of the objective function. They do not appear in the last two models that only are concerned with feasibility, and they only appear indirectly via the objective in the Full Model. The defined variables are considered intermediate variables in the definition of the remaining constraints in the same way as post-triangular variables are intermediate in the objective. The variables in the Full Model are all variables excluding pre- and post-triangular variables and excluding defined variables; this set can include variables that do not appear in any constraints. The constraints of the full models are all constraints excluding pre- and post-triangular constraints and with the definitional equations logically eliminated. The variables in the Linear Feasibility Model and in the No-Penalty Model are the variables that appear in the constraints of these models (excluding pre-triangular variables).

CONOPT always starts by searching for a feasible solution and the sub-models only play a role in this part of the optimization so if the initial point provided by the modeler is feasible then these sub-models are irrelevant. If there are many penalty and/or minimax constraints then the No-Penalty Model will be much smaller than the Full Model and it is more efficient to use the smaller model while searching for feasibility. So the No-Penalty model is only introduced for efficiency reasons. It is by default solved before the Full Model if all of the following conditions are satisfied:

- The `Flg_NoPen` options is true (the default value)

- The model is not a CNS model
- The user did not provide an initial basis
- Some of the constraints in the No-Penalty Model are infeasible.
- The number of penalty and minimax constraints is more than the number of constraints in the Full Model multiplied by the value of option `Rat_NoPen`. The default value of `Rat_NoPen` is 0.1, i.e. the No-Penalty Model is only defined and solved if it is at least 10% smaller than the Full Model.

The GAMS Library model **prolog.gms** used earlier has many penalty and minimax constraints. The relevant part of the log file is:

```

Iter Phase   Ninf   Infeasibility   RGmax       NSB   Step  InItr MX OK
   0    0           1.2977431398E+03 (Input point)
The post-triangular part of the model has 1 constraints and variables.
There are 17 penalty and minimax constraints with 3 variables.

Reduced model without penalty components has 17 variables and
5 constraints with 46 Jacobian elements, 0 of which are nonlinear.

Iter Phase   Ninf   Infeasibility   RGmax       NSB   Step  InItr MX OK
           1.2960000000E+03 (Model without penalty constraints)
           5.0625000000E+00 (After scaling)
           0.0000000000E+00 (After adjusting individual variables)

Previous model terminated and penalty components are added back in.
Full preprocessed model has 20 variables and 22 constraints
with 120 Jacobian elements, 8 of which are nonlinear.

Iter Phase   Ninf   Infeasibility   RGmax       NSB   Step  InItr MX OK
           0.0000000000E+00 (After adjusting penalty variables)

** Feasible solution. Value of objective =   -1147.54681404

```

The No-Penalty model is small with only 5 constraints and 17 variables and it solves already in the 'Adjust Individual Point' procedure. The Full Model is significantly larger with 22 constraints and 20 variables, and it is feasible when started from the solution to the No-Penalty model.

The Linear Feasibility Model is introduced to help avoid locally infeasible solutions. It produces a starting point to the nonlinear models (No-Penalty Model or Full Model) that satisfies all linear constraints. If the Linear Feasibility Model is infeasible then the overall model is proved to be infeasible (independent of nonlinearities) and there is no reason to proceed with the nonlinear part of the model.

The Linear Feasibility Model is only useful if the model has some linear constraints and if the initial point provided by the modeler does not satisfy these constraints. If a feasible solution to the linear constraints is found there are several possible ways to continue before the No-Penalty Model and/or the Full Model are started:

- Use the solution point as is.
- Perform an approximate minimization of the weighted distance from the user's initial point. Include only the variables that have non-default initial values, i.e. variables with an initial value (`xini`) that is different from zero projected on the bounds, i.e. `xini ne min(max(0,x.lo),x.up)`. The distance measure is `sqr( (x-xini) / max(1,abs(xini)) )`.
- As in B, but include all variables in the distance measure.
- As in C, but define `xini` to 1 projected on the bounds for all variables with default initial value.

Possibility A is fast but may give a starting point for the nonlinear model far from the initial point provided by the user, B is slower but gives a starting point for the nonlinear model that is close to the point provided by the user, and C and D are also slower but may provide reasonably good and different starting points for the nonlinear model.

The order in which the sub-models are solved depends on a Linear Feasibility Model strategy option, `Lin_Method`:

1. If `Lin_Method` has the default value 1 then the initial point and basis is assumed to be fairly good and CONOPT4 will start with the No-Penalty Model (only if the conditions mentioned above are satisfied) followed by the Full Model. If the model terminates locally optimal, unbounded, or on some resource limit (time, iterations, function evaluations) then we are done and CONOPT terminates. But if the model is locally infeasible then we build and solve the Linear Feasibility Model. If this model is infeasible, the overall model is infeasible and we are again done. If it is feasible we minimize objective B and use the solution point as a second starting point for the nonlinear model. If this attempt also terminates locally infeasible we try to generate an alternative initial point with objective C and then with objective D. If all fails, the model is labeled locally infeasible.
2. With `Lin_Method` = 2 CONOPT will start with the Linear Feasibility Model with objective A before looking at the No-Penalty and Full models. If they are locally infeasible from this starting point we followed the procedure from above with objective B, C, and then D.
3. `Lin_Method` = 3 is similar to `Lin_Method` = 2 except that the first objective A is skipped.

An example where all Linear Feasibility objectives are used is taken from `ex5.3.2.gms` in the GlobalLib collection of test models. It shows the repeated starts of the Linear Feasibility Model followed by the Full Preprocessed model:

```
Preprocessed model has 22 variables and 16 constraints
with 59 Jacobian elements, 24 of which are nonlinear.
```

Iter	Phase	Ninf	Infeasibility	RGmax	NSB	Step	InItr	MX	OK
			4.1200000000E+02						
			(Full preprocessed model)						
			8.4843750000E+00						
			(After scaling)						
			6.2500000000E-01						
			(After adjusting individual variables)						
1	1	1	6.2500000000E-01	0.0E+00	5	0.0E+00		T	T
4	1	1	6.2500000000E-01	0.0E+00	4				

```
** Infeasible solution. Reduced gradient less than tolerance.
```

```
Initial linear feasibility model has 22 variables and 7 constraints
with 22 linear Jacobian elements.
Objective: Distance to initial point (nondefault variables)
```

Iter	Phase	Ninf	Infeasibility	RGmax	NSB	Step	InItr	MX	OK
			3.0200000000E+02						
			(Linear feasibility model)						
			3.1718750000E+00						
			(After scaling)						

```
** Linear constraints feasible. Distance = 0.0000000000
```

Iter	Phase	Ninf	Distance	RGmax	NSB	Step	InItr	MX	OK
6	4		0.0000000000E+00	0.0E+00	0				

```
Restarting preprocessed model from a new starting point.
```

```

** Optimal solution. There are no superbasic variables.

The Full Model is infeasible when started directly from the values provided by the user. The Linear Feasibility model is then solved to get a different starting point for the Full model where the linear part is feasible. The Full Model is also infeasible from this point and it is necessary to solve the Linear Feasibility model three times with different objective functions before the full model becomes feasible.

The number of submodels that are solved is limited by the option, Num_Rounds. The default value is 4, i.e. we will try very hard to find a feasible point as shown in the example above. The value 1 will make CONOPT terminate immediately when a locally infeasible point is found. You can use Num_Rounds if you are not interested in spending a lot of time on a model that is likely to be infeasible. It can be particularly relevant if CONOPT4 is used as the sub-solver inside SBB where infeasible sub-problems are fairly likely.

If the model is defined to be convex with the option `Flg_Convex = true` then a locally infeasible solution is labeled (globally) infeasible and the Linear Feasibility Model will not be used. (A locally optimal solution is also labeled (globally) optimal.)

5.12.10 Multiple Threads

CONOPT4 can use multiple threads for some internal computations and in collaboration with GAMS for function and derivative evaluations. Multiple threads are currently only used for certain fairly large and dense computations and there are not so many of these in the types of model usually build with GAMS. In addition, multiple threads have quite high overhead and they are therefore only useful for fairly large models. Currently the best improvements have been for very large models with more than 100,000 variables or constraints, in particular for CNS models if this size.

It is the intention to implement multiple threads into more parts of CONOPT4 in the future.

Threads can be turned on with the GAMS command-line option `Threads=n` or with the CONOPT4 option `threads`.

5.12.11 APPENDIX A - Options

The options that ordinary GAMS users can access are listed below.

5.12.11.1 Algorithmic options

Option	Description	Default
DF_Method	Method used with defined variables	0
Flg_Convex	Flag for defining a model to be convex	0
Flg_Crash_Basis	Flag for crashing an initial basis without fixed slacks	1
Flg_Crash_Slack	Flag for pre-selecting slacks for the initial basis.	0
Flg_Dbg_Intv	Flag for debugging interval evaluations.	0
Flg_DC_Unique	Flag for requiring definitional constraints to be unique	1
Flg_NegCurve	Flag for testing for negative curvature when apparently optimal	1
Flg_NoPen	Flag for allowing the Model without penalty constraints	1
Flg_SLPMode	Flag for enabling SLP mode.	1

Option	Description	Default
Flg_SQPMode	Flag for enabling of SQP mode.	1
Flg_Square	Flag for Square System. Alternative to defining modeltype=CNS in GAMS	0
Frq_Rescale	Rescaling frequency.	5
Lim_DFVars	Limit on the number of candidates for defined variable in one constraint	2
Lim_Err_2DDir	Limit on errors in Directional Second Derivative evaluation.	10
Lim_Err_Fnc_Drv	Limit on number of function evaluation errors. Overwrites GAMS Domlim option	GAMS DomLim
Lim_Err_Hessian	Limit on errors in Hessian evaluation.	10
Lim_Iteration	Maximum number of iterations. Overwrites GAMS Iterlim option.	GAMS IterLim
Lim_NewSuper	Maximum number of new superbasic variables added in one iteration.	auto
Lim_RedHess	Maximum number of superbasic variables in the approximation to the Reduced Hessian.	auto
Lim_SlowPrg	Limit on number of iterations with slow progress (relative less than Tol_Obj_Change).	20
Lim_StallIter	Limit on the number of stalled iterations.	100
Lim_Start_Degen	Limit on number of degenerate iterations before starting degeneracy breaking strategy.	10
Lim_Time	Time Limit. Overwrites the GAMS Reslim option.	GAMS ResLim
Lim_Variable	Upper bound on solution values and equation activity levels	1.e15
Lin_Method	Method used to determine if and/or which Linear Feasibility Models to use	1
Mtd_Dbg_1Drv	Method used by the function and derivative debugger.	0
Mtd_RedHess	Method for initializing the diagonal of the approximate Reduced Hessian	0
Mtd_Scale	Method used for scaling.	3
Mtd_Step_Phase0	Method used to determine the step in Phase 0.	Auto
Mtd_Step_Tight	Method used to determine the maximum step while tightening tolerances.	0
Num_Rounds	Number of rounds with Linear Feasibility Model	4
Rat_NoPen	Limit on ratio of penalty constraints for the No_Penalty model to be solved	0.1
Tol_Bound	Bound filter tolerance for solution values close to a bound.	1.e-7
Tol_BoxSize	Initial box size for trust region models for overall model	10
Tol_BoxSize_Lin	Initial box size for trust region models for linear feasibility model	1000
Tol_Box_LinFac	Box size factor for linear variables applied to trust region box size	10
Tol_DFixed	Tolerance for defining variables as fixed based on derived bounds.	1.e-12
Tol_Feas_Max	Maximum feasibility tolerance (after scaling).	1.e-7
Tol_Feas_Min	Minimum feasibility tolerance (after scaling).	4.e-10
Tol_Feas_Tria	Feasibility tolerance for triangular equations.	1.0e-8

Option	Description	Default
Tol_IFixed	Tolerance for defining variables as fixed based on initial bounds.	1.e-9
Tol_Jac_Min	Filter for small Jacobian elements to be ignored during scaling.	1.e-5
Tol_Linesearch	Accuracy of One-dimensional search.	0.2
Tol_Obj_Acc	Relative accuracy of the objective function.	3.0e-13
Tol_Obj_Change	Limit for relative change in objective for well-behaved iterations.	3.0e-12
Tol_Optimality	Optimality tolerance for reduced gradient when feasible.	1.e-7
Tol_Opt_Infeas	Optimality tolerance for reduced gradient when infeasible.	1.e-7
Tol_Opt_LinF	Optimality tolerance when infeasible in Linear Feasibility Model	1.e-10
Tol_Piv_Abs	Absolute pivot tolerance.	1.e-10
Tol_Piv_Abs_Ini	Absolute Pivot Tolerance for building initial basis.	1.e-7
Tol_Piv_Abs_NLTr	Absolute pivot tolerance for nonlinear elements in pre-triangular equations.	1.e-5
Tol_Piv_Ratio	Relative pivot tolerance during ratio-test	1.e-8
Tol_Piv_Rel	Relative pivot tolerance during basis factorizations.	0.05
Tol_Piv_Rel_Ini	Relative Pivot Tolerance for building initial basis	1.e-3
Tol_Piv_Rel_Updt	Relative pivot tolerance during basis updates.	0.05
Tol_Scale2D_Min	Lower bound for scale factors based on large 2nd derivatives.	1.e-6
Tol_Scale_Max	Upper bound on scale factors.	1.e25
Tol_Scale_Min	Lower bound for scale factors computed from values and 1st derivatives.	1
Tol_Scale_Var	Lower bound on x in x*Jac used when scaling.	1.e-5
Tol_Zero	Zero filter for Jacobian elements and inversion results.	1.e-20

5.12.11.2 Debugging options

Option	Description	Default
Flg_Interv	Flag for using intervals in the Preprocessor	1
Flg_Prep	Flag for using the Preprocessor	1
Lim_Dbg_1Drv	Flag for debugging of first derivatives	0
Lim_Hess_Est	Upper bound on second order terms.	1.e4
Lim_Msg_Dbg_1Drv	Limit on number of error messages from function and derivative debugger.	10

5.12.11.3 Output options

Option	Description	Default
Frq_Log_Simple	Frequency for log-lines for non-SLP/SQP iterations.	auto

Option	Description	Default
Frq_Log_SlpSqp	Frequency for log-lines for SLP or SQP iterations.	auto
Lim_Msg_Large	Limit on number of error messages related to large function value and Jacobian elements.	10
Lim_Pre_Msg	Limit on number of error messages related to infeasible pre-triangle.	25

5.12.11.4 Interface options

Option	Description	Default
cooptfile		
Flg_2DDir	Flag for computing and using directional 2nd derivatives.	auto
Flg_Hessian	Flag for computing and using 2nd derivatives as Hessian of Lagrangian.	auto
HEAPLIMIT	Maximum Heap size in MB allowed	1e20
HessianMemFac	Memory factor for Hessian generation: Skip if Hessian elements > Nonlinear Jacobian elements*HessianMemFac, 0 means unlimited.	0
THREAD2D	Number of threads used for second derivatives	1
THREADC	Number of compatibility threads used for comparing different values of THREADS	1
THREADF	Number of threads used for function evaluation	1
threads	Number of threads used by Conopt internally	GAMS Threads

cooptfile (*string*): ↩

DF_Method (*integer*): Method used with defined variables ↩

When defined variables are identified (see [LSUSDF](#)) they can be used in two ways, controlled by DF_Method:

Default: 0

value	meaning
0	Defined variables are only used in the initial point and for the initial basis (default).
1	Defined variables are kept basic and the defining constraints are used to recursively assign values to the defined variables in all trial points.

Flg_2DDir (*boolean*): Flag for computing and using directional 2nd derivatives. ↩

If turned on, make directional second derivatives (Hessian matrix times directional vector) available to CONOPT. The default is on, but it will be turned off if the model has external equations (defined with =X=) and the user has not provided directional second derivatives. If both the Hessian of the Lagrangian (see [Flg_Hessian](#)) and directional second derivatives are available then CONOPT will use both: directional second derivatives are used when the expected number of iterations in the SQP sub-solver is low and the Hessian is used when the expected number of iterations is large.

Default: `auto`

Flg_Convex (*boolean*): Flag for defining a model to be convex [↔](#)

When turned on (the default is off) CONOPT knows that a local solution is also a global solution, whether it is optimal or infeasible, and it will be labeled appropriately. At the moment, Flg_NegCurve will be turned off. Other parts of the code will gradually learn to take advantage of this flag.

Default: 0

Flg_Crash_Basis (*boolean*): Flag for crashing an initial basis without fixed slacks [↔](#)

When turned on (1) CONOPT will try to crash a basis without fixed slacks in the basis. Fixed slacks are only included in a last round to fill linearly dependent rows. When turned off (0), large infeasible slacks will be included in the initial basis with preference for variables and slacks far from bound.

Default: 1

Flg_Crash_Slack (*boolean*): Flag for pre-selecting slacks for the initial basis. [↔](#)

When turned on (1) CONOPT will select all infeasible slacks as the first part of the initial basis.

Default: 0

Flg_Dbg_Intv (*boolean*): Flag for debugging interval evaluations. [↔](#)

Flg_Dbg_Intv controls whether interval evaluations are debugged. Currently we check that the lower bound does not exceed the upper bound for all intervals returned, both for function values and for derivatives.

Default: 0

Flg_DC_Unique (*boolean*): Flag for requiring definitional constraints to be unique [↔](#)

Flg_DC_Unique controls whether CONOPT will require definitional constraints to be unique. If turned on variables are excluded if they can be defined from more than one equation, and equations are excluded if they can be used to define more than one variable.

Default: 1

Flg_Hessian (*boolean*): Flag for computing and using 2nd derivatives as Hessian of Lagrangian. [↔](#)

If turned on, compute the structure of the Hessian of the Lagrangian and make it available to CONOPT. The default is usually on, but it will be turned off if the model has external equations (defined with `=X=`) or cone constraints (defined with `=C=`) or if the Hessian becomes too dense. See also [Flg_2DDir](#) and [HessianMemFac](#).

Default: `auto`

Flg_Interv (*boolean*): Flag for using intervals in the Preprocessor [↔](#)

If turned on (default), CONOPT will attempt to use interval evaluations in the preprocessor to determine if functions are monotone or if intervals for some of the variables can be excluded as infeasible.

Default: 1

Flg_NegCurve (*boolean*): Flag for testing for negative curvature when apparently optimal [↔](#)

When turned on (the default) CONOPT will try to identify directions with negative curvature when the model appears to be optimal. The objective is to move away from saddlepoints. Can be turned off when the model is known to be convex and cannot have negative curvature.

Default: 1

Flg_NoPen (*boolean*): Flag for allowing the Model without penalty constraints [↔](#)

When turned on (the default) CONOPT will create and solve a smaller model without the penalty constraints and variables and the minimax constraints and variables if the remaining constraints are infeasible in the initial point. This is often a faster way to start the solution process.

Default: 1

Flg_Prep (*boolean*): Flag for using the Preprocessor [↔](#)

If turned on (default), CONOPT will use its preprocessor to try to determine pre- and post-triangular components of the model and find definitional constraints.

Default: 1

Flg_SLPMode (*boolean*): Flag for enabling SLP mode. [↔](#)

If Flg_SLPMode is on (the default) then the SLP (sequential linear programming) sub-solver can be used, otherwise it is turned off.

Default: 1

Flg_SQPMode (*boolean*): Flag for enabling of SQP mode. [↔](#)

If Flg_SQPMode is on (the default) then the SQP (sequential quadratic programming) sub-solver can be used, otherwise it is turned off.

Default: 1

Flg_Square (*boolean*): Flag for Square System. Alternative to defining modeltype=CNS in GAMS [↔](#)

When turned on the modeler declares that this is a square system, i.e. the number of non-fixed variables must be equal to the number of constraints, no bounds must be active in the final solution, and the basis selected from the non-fixed variables must always be nonsingular.

Default: 0

Frq_Log_Simple (*integer*): Frequency for log-lines for non-SLP/SQP iterations. [↔](#)

Frq_Log_Simple and Frq_Log_SlpSqp can be used to control the amount of iteration sent to the log file. The non-SLP/SQP iterations, i.e. iterations in phase 0, 1, and 3, are usually fast and writing a log line for each iteration may be too much, especially for smaller models. The default value for the log frequency for these iterations is therefore set to 10 for small models, 5 for models with more than 500 constraints or 1000 variables and 1 for models with more than 2000 constraints or 3000 variables.

Default: auto

Frq_Log_SlpSqp (*integer*): Frequency for log-lines for SLP or SQP iterations. [↔](#)

Frq_Log_Simple and Frq_Log_SlpSqp can be used to control the amount of iteration send to the log file. Iterations using the SLP and/or SQP sub-solver, i.e. iterations in phase 2 and 4, may involve several inner iterations and the work per iteration is therefore larger than for the non-SLP/SQP iterations and it may be relevant to write log lines more frequently. The default value for the log frequency is therefore 5 for small models and 1 for models with more than 500 constraints or 1000 variables.

Default: `auto`

Frq_Rescale (*integer*): Rescaling frequency. [↩](#)

The row and column scales are recalculated at least every Frq_Rescale new point (degenerate iterations do not count), or more frequently if conditions require it.

Default: 5

HEAPLIMIT (*real*): Maximum Heap size in MB allowed [↩](#)

Range: $[0, \infty]$

Default: `1e20`

HessianMemFac (*real*): Memory factor for Hessian generation: Skip if Hessian elements > Nonlinear Jacobian elements*HessianMemFac, 0 means unlimited. [↩](#)

The Hessian of the Lagrangian is considered too dense therefore too expensive to evaluate and use, and it is not passed on to CONOPT if the number of nonzero elements in the Hessian of the Lagrangian is greater than the number of nonlinear Jacobian elements multiplied by HessianMemFac. See also Flg_Hessian. If HessianMemFac = 0.0 (the default value) then there is no limit on the number of Hessian elements.

The following cells are used to count calls of various routines and the time spend in them. The timing is usually only turned on if some debugging level is on and the statistics is only printed in these cases.

Default: 0

Lim_Dbg_1Drv (*integer*): Flag for debugging of first derivatives [↩](#)

Lim_Dbg_1Drv controls how often the derivatives are tested. Debugging of derivatives is only relevant for user-written functions in external equations defined with `=X=`. The amount of debugging is controlled by [Mtd_Dbg_1Drv](#). See [Lim_Hess_Est](#) for a definition of when derivatives are considered wrong.

Default: 0

value	meaning
-1	The derivatives are tested in the initial point only.
0	No debugging
+n	The derivatives are tested in all iterations that can be divided by Lim_Dbg_1Drv, provided the derivatives are computed in this iteration. (During phase 0, 1, and 3 derivatives are only computed when it appears to be necessary.)

Lim_DFVars (*integer*): Limit on the number of candidates for defined variable in one constraint [↩](#)

When there are more than one candidate that can be selected as a defined variable in a particular constraint CONOPT tries to select the most appropriate in order to select as many

defined variables as possible. However, to avoid too much arbitrariness this is only attempted if there are not more than Lim_DFvars candidates.

Default: 2

Lim_Err_2DDir (*integer*): Limit on errors in Directional Second Derivative evaluation. ↩

If the evaluation of Directional Second Derivatives (Hessian information in a particular direction) has failed more than Lim_Err_2DDir times CONOPT will not attempt to evaluate them any more and will switch to methods that do not use Directional Second Derivatives. Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like `power(x,1.5)` at `x=0`.

Default: 10

Lim_Err_Fnc_Drv (*integer*): Limit on number of function evaluation errors. Overwrites GAMS Domlim option ↩

Function values and their derivatives are assumed to be defined in all points that satisfy the bounds of the model. If the function value or a derivative is not defined in a point CONOPT will try to recover by going back to a previous safe point (if one exists), but it will not do it more than at most Lim_Err_Fnc_Drv times. If CONOPT is stopped by functions or derivatives not being defined it will return with a intermediate infeasible or intermediate non-optimal model status.

Default: GAMS DomLim

Lim_Err_Hessian (*integer*): Limit on errors in Hessian evaluation. ↩

If the evaluation of Hessian information has failed more than Lim_Err_Hessian times CONOPT will not attempt to evaluate it any more and will switch to methods that do not use the Hessian. Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like `power(x,1.5)` at `x=0`.

Default: 10

Lim_Hess_Est (*real*): Upper bound on second order terms. ↩

The function and derivative debugger (see [Lim_Dbg_1Drv](#)) tests if derivatives computed using the modelers routine are sufficiently close to the values computed using finite differences. The term for the acceptable difference includes a second order term and uses Lim_Hess_Est as an estimate of the upper bound on second order derivatives in the model. Larger Lim_Hess_Est values will allow larger deviations between the user-defined derivatives and the numerically computed derivatives.

Default: 1.e4

Lim_Iteration (*integer*): Maximum number of iterations. Overwrites GAMS Iterlim option. ↩

The iteration limit can be used to prevent models from spending too many resources. You should note that the cost of the different types of CONOPT iterations (phase 0 to 4) can be very different so the time limit (GAMS Reslim or option [Lim_Time](#)) is often a better stopping criterion. However, the iteration limit is better for reproducing solution behavior across machines.

Default: GAMS IterLim

Lim_Msg_Dbg_1Drv (*integer*): Limit on number of error messages from function and derivative debugger. ↩

The function and derivative debugger (see [Lim_Dbg_1Drv](#)) may find a very large number of errors, all derived from the same source. To avoid very large amounts of output CONOPT will stop the debugger after Lim_Msg_Dbg_1Drv error(s) have been found.

Default: 10

Lim_Msg_Large (*integer*): Limit on number of error messages related to large function value and Jacobian elements. [↩](#)

Very large function value or derivatives (Jacobian elements) in a model will lead to numerical difficulties and most likely to inaccurate primal and/or dual solutions. CONOPT is therefore imposing an upper bound on the value of all function values and derivatives. This bound is 1.e30. If the bound is violated CONOPT will return with an intermediate infeasible or intermediate non-optimal solution and it will issue error messages for all the violating Jacobian elements, up to a limit of Lim_Msg_Large error messages.

Default: 10

Lim_NewSuper (*integer*): Maximum number of new superbasic variables added in one iteration. [↩](#)

When there has been a sufficient reduction in the reduced gradient in one subspace new non-basics can be selected to enter the superbasis. The ones with largest reduced gradient of proper sign are selected, up to a limit. If Lim_NewSuper is positive then the limit is min(500,Lim_NewSuper). If Lim_NewSuper is zero (the default) then the limit is selected dynamically by CONOPT depending on model characteristics.

Default: auto

Lim_Pre_Msg (*integer*): Limit on number of error messages related to infeasible pre-triangle. [↩](#)

If the pre-processor determines that the model is infeasible it tries to define a minimal set of variables and constraints that define the infeasibility. If this set is larger than Lim_Pre_Msg elements the report is considered difficult to use and it is skipped.

Default: 25

Lim_RedHess (*integer*): Maximum number of superbasic variables in the approximation to the Reduced Hessian. [↩](#)

CONOPT uses and stores a dense lower-triangular matrix as an approximation to the Reduced Hessian. The rows and columns correspond to the superbasic variable. This matrix can use a large amount of memory and computations involving the matrix can be time consuming so CONOPT imposes a limit on the size. The limit is Lim_RedHess if Lim_RedHess is defined by the modeler and otherwise a value determined from the overall size of the model. If the number of superbasis exceeds the limit, CONOPT will switch to a method based on a combination of SQP and Conjugate Gradient iterations assuming some kind of second order information is available. If no second order information is available CONOPT will use a quasi-Newton method on a subset of the superbasic variables and rotate the subset as the reduced gradient becomes small.

Default: auto

Lim_SlowPrg (*integer*): Limit on number of iterations with slow progress (relative less than Tol_Obj_Change). [↩](#)

The optimization is stopped if the relative change in objective is less than [Tol_Obj_Change](#) for Lim_SlowPrg consecutive well-behaved iterations.

Default: 20

Lim_StallIter (*integer*): Limit on the number of stalled iterations. ↩

An iteration is considered a stalled iteration if there is no change in objective because the linesearch is limited by nonlinearities or numerical difficulties. Stalled iterations will have Step = 0 and F in the OK column of the log file. After a stalled iteration CONOPT will try various heuristics to get a better basis and a better search direction. However, the heuristics may not work as intended or they may even return to the original bad basis, especially if the model does not satisfy standard constraints qualifications and does not have a KKT point. To prevent cycling CONOPT will therefore stop after Lim_StallIter stalled iterations and returns an Intermediate Infeasible or Intermediate Nonoptimal solution.

Default: 100

Lim_Start_Degen (*integer*): Limit on number of degenerate iterations before starting degeneracy breaking strategy. ↩

The default CONOPT pivoting strategy has focus on numerical stability, but it can potentially cycle. When the number of consecutive degenerate iterations exceeds Lim_Start_Degen CONOPT will switch to a pivoting strategy that is guaranteed to break degeneracy but with slightly weaker numerical properties.

Default: 10

Lim_Time (*real*): Time Limit. Overwrites the GAMS Reslim option. ↩

The upper bound on the total number of seconds that can be used in the execution phase. There are only tests for time limit once per iteration. The default value is 10000. Lim_Time is overwritten by Reslim when called from GAMS.

Range: $[0, \infty]$

Default: GAMS ResLim

Lim_Variable (*real*): Upper bound on solution values and equation activity levels ↩

If the value of a variable, including the objective function value and the value of slack variables, exceeds Lim_Variable then the model is considered to be unbounded and the optimization process returns the solution with the large variable flagged as unbounded. A bound cannot exceed this value.

Range: $[1.e5, 1.e30]$

Default: 1.e15

Lin_Method (*integer*): Method used to determine if and/or which Linear Feasibility Models to use ↩

1 - Ignore Linear Feasibility Model in the first round and use objective 2, 3, and 4 in the following rounds as long as model is locally infeasible. This is the default method. 2 - Use Linear Feasibility Model with objective 1 in the first round and continue with objective 2, 3, and 4 in the following rounds as long as model is locally infeasible. 3 - Use Linear Feasibility Model with objective 2 in the first round and continue with objective 3 and 4 in the following rounds as long as model is locally infeasible.

Range: $[0, 3]$

Default: 1

Mtd_Dbg_1Drv (*integer*): Method used by the function and derivative debugger. ↩

The function and derivative debugger (turned on with [Lim_Dbg_1Drv](#)) can perform a fairly cheap test or a more extensive test, controlled by Mtd_Dbg_1Drv. See [Lim_Hess_Est](#) for a definition of when derivatives are considered wrong. All tests are performed in the current point found by the optimization algorithm.

Default: 0

value	meaning
0	Perform tests for sparsity pattern and tests that the numerical values of the derivatives appear to be correct. This is the default.
1	As 0 plus make extensive test to determine if the functions and their derivatives are continuous around the current point. These tests are much more expensive and should only be used if the cheap test does not find an error but one is expected to exist.

Mtd_RedHess (*integer*): Method for initializing the diagonal of the approximate Reduced Hessian ↩

Each time a nonbasic variable is made superbasic a new row and column is added to the approximate Reduced Hessian. The off-diagonal elements are set to zero and the diagonal to a value controlled by Mtd_RedHess:

Default: 0

value	meaning
0	The new diagonal element is set to the geometric mean of the existing diagonal elements. This gives the new diagonal element an intermediate value and new superbasic variables are therefore not given any special treatment. The initial steps should be of good size, but build-up of second order information in the new sub-space may be slower. The larger diagonal element may also in bad cases cause premature convergence.
1	The new diagonal elements is set to the minimum of the existing diagonal elements. This makes the new diagonal element small and the importance of the new superbasic variable will therefore be high. The initial steps can be rather small, but better second order information in the new sub-space should be build up faster.

Mtd_Scale (*integer*): Method used for scaling. ↩

CONOPT will by default use scaling of the equations and variables of the model to improve the numerical behavior of the solution algorithm and the accuracy of the final solution (see also [Frq_Rescale](#).) The objective of the scaling process is to reduce the values of all large primal and dual variables as well as the values of all large first derivatives so they become closer to 1. Small values are usually not scaled up, see [Tol_Scale_Max](#) and [Tol_Scale_Min](#). Scaling method 3 is recommended. The others are only kept for backward compatibility.

Default: 3

value	meaning
0	Scaling is based on repeatedly dividing the rows and columns by the geometric means of the largest and smallest elements in each row and column. Very small elements less than Tol_Jac_Min are considered equal to Tol_Jac_Min.
1	Similar to 3 below, but the projection on the interval [Tol_Scale_Min,Tol_Scale_Max] is applied at a different stage. With method 1, $\text{abs}(X) \cdot \text{abs}(\text{Jac})$ with small X and very large Jac is scaled very aggressively with a factor $\text{abs}(\text{Jac})$. With method 3, the scale factor is $\text{abs}(X) \cdot \text{abs}(\text{Jac})$. The difference is seen in models with terms like $\text{Sqrt}(X)$ close to $X = 0$.
2	As 1 but the terms are computed based on a moving average of the squares X and Jac. The purpose of the moving average is to keep the scale factor more stable. This is often an advantage, but for models with very large terms (large variables and in particular large derivatives) in the initial point the averaging process may not have enough time to bring the scale factors into the right region.

value	meaning
3	Rows are first scaled by dividing by the largest term in the row, then columns are scaled by dividing by the maximum of the largest term and the value of the variable. A term is here defined as $\text{abs}(X) \cdot \text{abs}(\text{Jac})$ where X is the value of the variable and Jac is the value of the derivative (Jacobian element). The scale factor are then projected on the interval between Tol_Scale_Min and Tol_Scale_Max .

Mtd_Step_Phase0 (*integer*): Method used to determine the step in Phase 0. ↩

The steplength used by the Newton process in phase 0 is computed by one of two alternative methods controlled by **Mtd_Step_Phase0**:

Default: Auto

value	meaning
0	The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this method. It is the default method for optimization models.
1	A method based on bending (projecting the target values of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum. Linear constraints that initially are feasible may become infeasible due to bending.

Mtd_Step_Tight (*integer*): Method used to determine the maximum step while tightening tolerances. ↩

The steplength used by the Newton process when tightening tolerances is computed by one of two alternative methods controlled by **Mtd_Step_Tight**:

Default: 0

value	meaning
0	The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this default method.
1	A method based on bending (projecting the target value of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum.

Num_Rounds (*integer*): Number of rounds with Linear Feasibility Model ↩

Lin_Method defined which Linear Feasibility Model are going to be solved if the previous models end Locally Infeasible. The number of rounds is limited by **Num_Rounds**.

Range: [1, 4]

Default: 4

Rat_NoPen (*real*): Limit on ratio of penalty constraints for the No-Penalty model to be solved ↩

The No-Penalty model can only be generated and solved if the number of penalty and minimax constraints exceed **Rat_NoPen** times the constraints in the Full Model.

Default: 0.1

THREAD2D (*integer*): Number of threads used for second derivatives ↩

Range: $[0, \infty]$

Default: 1

THREADC (*integer*): Number of compatibility threads used for comparing different values of THREADS ↩

Range: $[0, \infty]$

Default: 1

THREADF (*integer*): Number of threads used for function evaluation ↩

Range: $[0, \infty]$

Default: 1

threads (*integer*): Number of threads used by Conopt internally ↩

Range: $[0, \infty]$

Default: GAMS Threads

Tol_Bound (*real*): Bound filter tolerance for solution values close to a bound. ↩

A variable is considered to be at a bound if its distance from the bound is less than Tol_Bound * Max(1,ABS(Bound)). The tolerance is used to build the initial bases and is used to flag variables during output.

Range: $[3.e-13, 1.e-5]$

Default: 1.e-7

Tol_BoxSize (*real*): Initial box size for trust region models for overall model ↩

The new Phase 0 methods solves an LP model based on a scaled and linearized version of the model with an added trust region box constraint around the initial point. Tol_BoxSize defines the size of the initial trust region box. During the optimization the trust region box is adjusted based on how well the linear approximation fits the real model.

Range: $[0.01, 1.e6]$

Default: 10

Tol_BoxSize_Lin (*real*): Initial box size for trust region models for linear feasibility model ↩

Similar to Tol_BoxSize but applied to the linear feasibility model. Since this model has linear constraints the default initial box size is larger.

Range: $[0.01, 1.e8]$

Default: 1000

Tol_Box_LinFac (*real*): Box size factor for linear variables applied to trust region box size ↩

The trust region box used in the new Phase 0 method limits the change of variables so 2nd order terms will not become too large. Variables that appear linearly do not have 2nd order terms and the initial box size is therefore larger by a factor `Tol_Box_LinFac`.

Parameters related to scaling

Range: `[1, 1.e4]`

Default: 10

Tol_DFixed (*real*): Tolerance for defining variables as fixed based on derived bounds. [↔](#)

A variable is considered fixed if the distance between the bounds is less than `Tol_DFixed * Max(1, Abs(Bound))`. The tolerance is used both on the users original bounds and on the derived bounds that the preprocessor implies from the constraints of the model.

Accuracies for linesearch and updates

Range: `[3.e-13, 1.e-8]`

Default: `1.e-12`

Tol_Feas_Max (*real*): Maximum feasibility tolerance (after scaling). [↔](#)

The feasibility tolerance used by CONOPT is dynamic. As long as we are far from the optimal solution and make large steps it is not necessary to compute intermediate solutions very accurately. When we approach the optimum and make smaller steps we need more accuracy. `Tol_Feas_Max` is the upper bound on the dynamic feasibility tolerance and `Tol_Feas_Min` is the lower bound.

Range: `[1.e-10, 1.e-3]`

Default: `1.e-7`

Tol_Feas_Min (*real*): Minimum feasibility tolerance (after scaling). [↔](#)

See `Tol_Feas_Max` for a discussion of the dynamic feasibility tolerances used by CONOPT.

Range: `[3.e-13, 1.e-5]`

Default: `4.e-10`

Tol_Feas_Tria (*real*): Feasibility tolerance for triangular equations. [↔](#)

Triangular equations are usually solved to an accuracy of `Tol_Feas_Min`. However, if a variable reaches a bound or if a constraint only has pre-determined variables then the feasibility tolerance can be relaxed to `Tol_Feas_Tria`.

Initial objective values and bounds

Range: `[3.e-13, 1.e-4]`

Default: `1.0e-8`

Tol_IFixed (*real*): Tolerance for defining variables as fixed based on initial bounds. [↔](#)

A variable is considered fixed if the distance between the bounds defined by the user is less than $\text{Tol\_IFixed} * \text{Max}(1, \text{Abs}(\text{Bound}))$.

Range: $[3.e-13, 1.e-5]$

Default: $1.e-9$

Tol_Jac_Min (*real*): Filter for small Jacobian elements to be ignored during scaling. [↔](#)

A Jacobian element is considered insignificant if it is less than Tol_Jac_Min. The value is used to select which small values are scaled up during scaling of the Jacobian. Is only used with scaling method Mtd.Scale = 0.

Range: $[1.e-7, 1.e-3]$

Default: $1.e-5$

Tol_Linesearch (*real*): Accuracy of One-dimensional search. [↔](#)

The onedimensional search is stopped if the expected decrease in then objective estimated from a quadratic approximation is less than Tol_Linesearch times the decrease so far in this onedimensional search.

Range: $[0.05, 0.8]$

Default: 0.2

Tol_Obj_Acc (*real*): Relative accuracy of the objective function. [↔](#)

It is assumed that the objective function can be computed to an accuracy of Tol_Obj_Acc * $\max(1, \text{abs}(\text{Objective}))$. Smaller changes in objective are considered to be caused by round-off errors.

Range: $[3.0e-14, 10.e-6]$

Default: $3.0e-13$

Tol_Obj_Change (*real*): Limit for relative change in objective for well-behaved iterations. [↔](#)

The change in objective in a well-behaved iteration is considered small and the iteration counts as slow progress if the change is less than Tol_Obj_Change * $\text{Max}(1, \text{Abs}(\text{Objective}))$. See also [Lim_SlowPrg](#).

Range: $[3.0e-13, 1.0e-5]$

Default: $3.0e-12$

Tol_Optimality (*real*): Optimality tolerance for reduced gradient when feasible. [↔](#)

The reduced gradient is considered zero and the solution optimal if the largest superbasic component of the reduced gradient is less than Tol_Optimality.

Range: $[3.e-13, 1]$

Default: $1.e-7$

Tol_Opt_Infeas (*real*): Optimality tolerance for reduced gradient when infeasible. [↔](#)

The reduced gradient is considered zero and the solution infeasible if the largest superbasic component of the reduced gradient is less than Tol_Opt_Infeas.

Range: [3.e-13, 1]

Default: 1.e-7

Tol_Opt_LinF (*real*): Optimality tolerance when infeasible in Linear Feasibility Model [↔](#)

This is a special optimality tolerance used when the Linear Feasibility Model is infeasible. Since the model is linear the default value is smaller than for nonlinear submodels.

Pivot tolerances

Range: [3.e-13, 1.e-4]

Default: 1.e-10

Tol_Piv_Abs (*real*): Absolute pivot tolerance. [↔](#)

During LU-factorization of the basis matrix a pivot element is considered large enough if its absolute value is larger than Tol_Piv_Abs. There is also a relative test, see [Tol_Piv_Rel](#).

Range: [2.2e-16, 1.e-7]

Default: 1.e-10

Tol_Piv_Abs_Ini (*real*): Absolute Pivot Tolerance for building initial basis. [↔](#)

Absolute pivot tolerance used during the search for a first logically non-singular basis. The default is fairly large to encourage a better conditioned initial basis.

Range: [3.e-13, 1.e-3]

Default: 1.e-7

Tol_Piv_Abs_NLTr (*real*): Absolute pivot tolerance for nonlinear elements in pre-triangular equations. [↔](#)

The smallest pivot that can be used for nonlinear or variable Jacobian elements during the pre-triangular solve. The pivot tolerance for linear or constant Jacobian elements is Tol_Piv_Abs. The value cannot be less than Tol_Piv_Abs.

Range: [2.2e-16, 1.e-3]

Default: 1.e-5

Tol_Piv_Ratio (*real*): Relative pivot tolerance during ratio-test [↔](#)

During ratio-tests, the lower bound on the slope of a basic variable to potentially leave the basis is Tol_Piv_Ratio * the largest term in the computation of the tangent.

Range: [1.e-10, 1.e-6]

Default: 1.e-8

Tol_Piv_Rel (*real*): Relative pivot tolerance during basis factorizations. [↔](#)

During LU-factorization of the basis matrix a pivot element is considered large enough relative to other elements in the column if its absolute value is at least Tol_Piv_Rel * the largest absolute value in the column. Small values of Tol_Piv_Rel will often give a sparser basis factorization at the expense of the numerical accuracy. The value used internally is therefore adjusted dynamically between the users value and 0.9, based on various statistics collected during the solution process. Certain models derived from finite element approximations of partial differential equations can give rise to poor numerical accuracy and a larger user-value of Tol_Piv_Rel may help.

Range: [1.e-3, 0.9]

Default: 0.05

Tol_Piv_Rel_Ini (*real*): Relative Pivot Tolerance for building initial basis [↔](#)

Relative pivot tolerance used during the search for a first logically non-singular basis.

Range: [1.e-4, 0.9]

Default: 1.e-3

Tol_Piv_Rel_Updt (*real*): Relative pivot tolerance during basis updates. [↔](#)

During basischanges CONOPT attempts to use cheap updates of the LU-factors of the basis. A pivot is considered large enough relative to the alternatives in the column if its absolute value is at least Tol_Piv_Rel_Updt * the other element. Smaller values of Tol_Piv_Rel_Updt will allow sparser basis updates but may cause accumulation of larger numerical errors.

Range: [1.e-3, 0.9]

Default: 0.05

Tol_Scale2D_Min (*real*): Lower bound for scale factors based on large 2nd derivatives. [↔](#)

Scaling of the model is in most cases based on the values of the variables and the first derivatives. However, if the scaled variables and derivatives are reasonable but there are large values in the Hessian of the Lagrangian (the matrix of 2nd derivatives) then the lower bound on the scale factor can be made smaller than Tol_Scale_Min. CONOPT will try to scale variables with large 2nd derivatives by one over the square root of the diagonal elements of the Hessian. However, the revised scale factors cannot be less than Tol_Scale2D_Min.

Range: [1.e-9, 1]

Default: 1.e-6

Tol_Scale_Max (*real*): Upper bound on scale factors. [↔](#)

Scale factors are projected on the interval from Tol_Scale_Min to Tol_Scale_Max. Is used to prevent very large or very small scale factors due to pathological types of constraints. The upper limit is selected such that Square(X) can be handled for X close to Lim_Variable. More nonlinear functions may not be scalable for very large variables.

Range: [1, 1.e30]

Default: 1.e25

Tol_Scale_Min (*real*): Lower bound for scale factors computed from values and 1st derivatives. [↔](#)

Scale factors used to scale variables and equations are projected on the range Tol.Scale.Min to Tol.Scale.Max. The limits are used to prevent very large or very small scale factors due to pathological types of constraints. The default value for Tol.Scale.Min is 1 which means that small values are not scaled up. If you need to scale small value up towards 1 then you must define a value of Tol.Scale.Min < 1 .

Range: $[1.e-10, 1]$

Default: 1

Tol.Scale.Var (*real*): Lower bound on x in $x*Jac$ used when scaling. [↩](#)

Rows are scaled so the largest term $x*Jac$ is around 1. To avoid difficulties with models where Jac is very large and x very small a lower bound of Tol.Scale.Var is applied to the x -term.

Largest Jacobian element and tolerance in 2nd derivative tests:

Range: $[1.e-8, 1]$

Default: $1.e-5$

Tol.Zero (*real*): Zero filter for Jacobian elements and inversion results. [↩](#)

Contains the smallest absolute value that an intermediate result can have. If it is smaller, it is set to zero. It must be smaller than [Tol.Piv.Abs](#)/10.

Default: $1.e-20$

5.13 CONVERT

5.13.1 Introduction

CONVERT is a utility which transforms a GAMS model instance into a scalar model where all confidential information has been removed or into formats used by other modeling and solution systems. CONVERT is designed to achieve the following goals:

- Permit users to convert a confidential model into GAMS scalar format so that any identifiable structure is removed. It can then be passed on to others for investigation without confidentiality being lost.
- A way of sharing GAMS test problems for use with other modeling systems or solvers.

CONVERT comes free of charge with any licensed GAMS system and can convert GAMS models into a number of formats, see Section [Target languages](#) for a list.

5.13.2 How to use CONVERT

CONVERT is run like any other GAMS solver. From the command line this is:

```
>> gams modelname modeltype=convert
```

where **modelname** is the GAMS model name and **modeltype** the solver indicator for a particular model type (e.g. LP, MIP, RMIP, QCP, MIQCP, RMIQCP, NLP, DNLP, CNS, MINLP, or MCP). CONVERT can also be specified via the option statement within the model itself before the solve statement:

```
option modeltype=convert;
```

5.13.3 The GAMS Scalar Format

By default, CONVERT generates a scalar GAMS model (`gams.gms`) from the input model. The scalar model exhibits the following characteristics:

- A model without sets or indexed parameters. It does not exhibit any of the advanced characteristics of modeling systems and is easily transformable.
- A model with a new set of individual variables, depicting each variable in the GAMS model as one of 3 types: positive, integer or binary. Each variable is numbered sequentially, i.e. all positive GAMS variables are mapped into n single variables `x1`, `x2`, ..., `xn`.
- A model with individual equations depicting each variable in the GAMS model. All equations are also numbered sequentially, that is equations `e1`, `e2`, ..., `em`.

Equation and variable bounds, as well as variable starting values are preserved from the original GAMS formulation.

As an example, suppose the user wishes to translate the GAMS Model Library model **transport** into scalar format. One would run

```
gams transport.gms lp=convert
```

which would generate the following scalar model `gams.gms`:

```
* LP written by GAMS Convert at 07/29/04 12:59:58
*
* Equation counts
*      Total      E      G      L      N      X      C
*        6        1      3      2      0      0      0
*
* Variable counts
*           x      b      i      s1s      s2s      sc      si
*      Total  cont  binary integer  sos1  sos2  scont  sint
*         7      7      0      0      0      0      0      0
* FX      0      0      0      0      0      0      0      0
*
* Nonzero counts
*      Total  const      NL      DLL
*        19      19      0      0
*
* Solve m using LP minimizing x7;

Variables  x1,x2,x3,x4,x5,x6,x7;
Positive Variables  x1,x2,x3,x4,x5,x6;
Equations  e1,e2,e3,e4,e5,e6;

e1..  - 0.225*x1 - 0.153*x2 - 0.162*x3 - 0.225*x4 - 0.162*x5 - 0.126*x6 + x7
      =E= 0;
e2..   x1 + x2 + x3 =L= 350;
e3..   x4 + x5 + x6 =L= 600;
e4..   x1 + x4 =G= 325;
e5..   x2 + x5 =G= 300;
e6..   x3 + x6 =G= 275;
```

```
* set non default bounds

* set non default levels

* set non default marginals
```

```
Model m / all /;
m.limrow=0; m.limcol=0;

Solve m using LP minimizing x7;
```

Note that the resulting scalar model does not contain any of the descriptive information about the data or the context of the constraints.

Additionally, a dictionary file (`dict.txt`) is created by default which specifies a mapping between the variable and equation names in the scalar model and their corresponding names in the original model.

For the above example, the dictionary file is

LP written by GAMS Convert at 07/29/04 12:59:59

Equation counts

Total	E	G	L	N	X	C	B
6	1	3	2	0	0	0	0

Variable counts

	x	b	i	s1s	s2s	sc	si
Total	cont	binary	integer	sos1	sos2	scont	sint
7	7	0	0	0	0	0	0
FX	0	0	0	0	0	0	0

Nonzero counts

Total	const	NL	DLL
19	19	0	0

Equations 1 to 6

```
e1 cost
e2 supply(seattle)
e3 supply(san-diego)
e4 demand(new-york)
e5 demand(chicago)
e6 demand(topeka)
```

Variables 1 to 7

```
x1 x(seattle,new-york)
x2 x(seattle,chicago)
x3 x(seattle,topeka)
x4 x(san-diego,new-york)
x5 x(san-diego,chicago)
x6 x(san-diego,topeka)
x7 z
```

Conversion of a GAMS model to a scalar one may be handy for model debugging. However, in this case, it may be good to retain the original variable and equation names. The following simple sed command attempts to achieve this:

```
sed -n -e "s:~ *\([exbi][0-9][0-9]*\) \(.*\):s/\1/\2/g:gp" dict.txt | sed -n '1!G;h;$p' > mod.txt
sed -f mod.txt gams.gms
```

For the above example, this outputs:

```
Variables x(seattle,new-york),x(seattle,chicago),x(seattle,topeka),x(san-diego,new-york),
          x(san-diego,chicago),x(san-diego,topeka),z;
```

```
Positive Variables x(seattle,new-york),x(seattle,chicago),x(seattle,topeka),
                  x(san-diego,new-york),x(san-diego,chicago),x(san-diego,topeka);
```

```
Equations cost,supply(seattle),supply(san-diego),demand(new-york),demand(chicago),demand(topeka);
```

```
cost.. - 0.225*x(seattle,new-york) - 0.153*x(seattle,chicago) - 0.162*x(seattle,topeka)
        - 0.225*x(san-diego,new-york) - 0.162*x(san-diego,chicago) - 0.126*x(san-diego,topeka) + z
        =E= 0;
```

```
supply(seattle).. x(seattle,new-york) + x(seattle,chicago) + x(seattle,topeka) =L= 350;
```

```
supply(san-diego).. x(san-diego,new-york) + x(san-diego,chicago) + x(san-diego,topeka) =L= 600;
```

```
demand(new-york).. x(seattle,new-york) + x(san-diego,new-york) =G= 325;
```

```
demand(chicago).. x(seattle,chicago) + x(san-diego,chicago) =G= 300;
```

```
demand(topeka).. x(seattle,topeka) + x(san-diego,topeka) =G= 275;
```

Of course, this is not a valid GAMS code and cannot be compiled, but it may be sufficient to view the model algebra as generated by the GAMS compiler.

By using

```
sed -n -e "y/()/,-/_/_/_/" -e "s:~ *\([exbi][0-9][0-9]*\) \(.*\):s/\1/\2/g:gp" dict.txt | sed -n '1!G;h;$p' > mod.txt
sed -f mod.txt gams.gms
```

one gets for this example

```
Variables x_seattle_new_york_,x_seattle_chicago_,x_seattle_topeka_,x_san_diego_new_york_,
          x_san_diego_chicago_,x_san_diego_topeka_,z;
```

```
Positive Variables x_seattle_new_york_,x_seattle_chicago_,x_seattle_topeka_,x_san_diego_new_york_,
                  x_san_diego_chicago_,x_san_diego_topeka_;
```

```
Equations cost,supply_seattle_,supply_san_diego_,demand_new_york_,demand_chicago_,demand_topeka_;
```

```
cost.. - 0.225*x_seattle_new_york_ - 0.153*x_seattle_chicago_ - 0.162*x_seattle_topeka_
        - 0.225*x_san_diego_new_york_ - 0.162*x_san_diego_chicago_ - 0.126*x_san_diego_topeka_ + z
        =E= 0;
```

```
supply_seattle.. x_seattle_new_york_ + x_seattle_chicago_ + x_seattle_topeka_ =L= 350;
```

```
supply_san_diego.. x_san_diego_new_york_ + x_san_diego_chicago_ + x_san_diego_topeka_ =L= 600;
```

```

demand_new_york_..    x_seattle_new_york_ + x_san_diego_new_york_ =G= 325;

demand_chicago_..    x_seattle_chicago_ + x_san_diego_chicago_ =G= 300;

demand_topeka_..    x_seattle_topeka_ + x_san_diego_topeka_ =G= 275;

```

This can even be compiled by GAMS and gives the correct solution.

The proposed commands come with several limitations and may not produce in all cases the desired output. For example, wrong results would be printed if the original model contains variable or equation names that start with `{b,i,e,x}[digit]`. Also semicontinuous or semiinteger variables or special ordered sets are not supported by the above. We leave it to the experienced user to extend the command appropriately.

5.13.4 The OSiL Format

The Optimization Services Instance Language (OSiL) [99] specifies an XML-based format to represent optimization problem instances. GAMS/CONVERT can write MINLP model instances in **OSiL format**. Expression trees are written in **OSnL format**.

Next to the **indexed operations** for sum, product, minimum, and maximum, and the operations for subtraction and division, the following **intrinsic functions** are mapped to their **OSnL** counterparts: `sqr`, `sqrt`, `exp`, `log`, `log2`, `log10`, `abs`, `cos`, `sin`, `tan`, `arccos`, `arcsin`, `arctan`, `sinh`, `cosh`, `tanh`, `pi`, `div`, `gamma`, `loggamma`, `floor`, `ceil`, `round`, `trunc`, `sign`, `fact`, `binomial`. The functions `cvPower`, `power`, `rpower`, `vcpower` are all mapped to OSnL's power operator, thus conditions on arguments are not preserved. Functions `arctan2`, `centropy`, `edist`, `errorf`, and `poly` are represented by an expression according to their algebraic definition. The intrinsic functions `signpower`, `entropy`, `sigmoid`, `gammareg`, `beta`, `logbeta`, and `betareg` are also written to OSiL files, but do not follow the OSnL standard (as it currently does not offer these functions). Thus, OSiL readers may reject XML files that use these functions. Finally, also the **logical functions** are written to OSiL by using their OSnL counterpart.

5.13.5 User-Specified Options

CONVERT options are passed on through option files. If you specify `<modelname>.optfile = 1;` before the SOLVE statement in your GAMS model, CONVERT will look for and read an option file with the name `convert.opt` (see [The Solver Options File](#) for general use of solver option files). The syntax for the CONVERT option file is

```
optname value
```

with one option on each line. For example,

```
ampl
```

This option file would tell CONVERT to produce an AMPL input file. For file format options, the user can specify the filename for the file to be generated. For example, the option file entry

```
lingo myfile.lng
```

would generate a LINGO input file format called `myfile.lng`. Using the option `lingo` by itself, would produce the default output file for that option (`lingo.lng`).

All available options are listed in the following tables.

5.13.5.1 Target languages

Option	Description	Default
All	Generates all supported file formats	
AlphaECP	Generates AlphaECP input file	alpha.ecp
Ampl	Generates Ampl input file	ampl.mod
AmplNLC	Generate Ampl NLC compatible file	amplnlc.c
Analyze	Generates three text files for rows columns and matrix	analyze.txt
AnalyzeS	Generates short form of Analyze	analyzes.txt
Baron	Generates Baron input file	gams.bar
CplexLP	Generate CPLEX LP format input file	cplex.lp
CplexMPS	Generate CPLEX MPS format input file	cplex.mps
Dict	Generate Convert to GAMS Dictionary	dict.txt
DictMap	Generate Convert to GAMS Dictionary Map	dictmap.gdx
FileList	Generate file list of file formats generated	files.txt
FixedMPS	Generate fixed format MPS file	fixed.mps
Gams	Generate GAMS scalar model. This is the default conversion format used.	gams.gms
Lgo	Generate an LGO Fortran file	lgomain.for
LindoMPI	Generate Lindo MPI file	lindo.mpi
Lingo	Generate Lingo input file	lingo.lng
LocalSolver	Generate LocalSolver input file (only with ConvertD)	localsolver.lsp
LSPSol	Generate Output function in LocalSolver input file (only with ConvertD)	lspsol.gms
Memo	Generate a memo file containing model statistics and files created.	memo.txt
Minopt	Generate Minopt input file	minopt.dat
NLP2dual	Generate the Wolfe dual of a smooth optimization model	gamsdual.gms
NLP2MCP	Generates GAMS scalar MCP model	gamsmcp.gms
OSiL	Generates Optimization Services instance Language (OSiL) file	osil.xml
Pyomo	Generates Pyomo Concrete scalar model	gams.py
SFS	Generates Solver Foundation Services OML file	sfs.oml
ViennaDag	Generate Vienna Dag input file	vienna.dag

5.13.5.2 Other options

Option	Description	Default
ConeReform	Reformulation of cone =C= constraints to NLP format 0: keep =C= format 1: convert conic constraints to NLP format	0
DualType	Controls type of Wolfe dual to generate None : No Wolfe dual generated NLPScalarBounds : NLP dual where variable bounds become scalars used in equations NLPConstantBounds : NLP dual where finite variable bounds become constants in equations BiLevel : Bilevel model with outer problem optimizing over the duals MPEC : MPEC obtained by explicitly including FOC of BiLevel inner problem	None
GmsInsert	Line to be inserted before the solve statement	<code>\$if NOT 'gams.u1' == '' \$include 'gams.u1'</code>
headerTimeStamp	Control format of time stamp in header of output file None : Use no timestamp default : Use the traditional default timestamp svnId : Use the SVN keyword Id as a timestamp svnLastChangedDate : Use the SVN keyword LastChangedDate as a timestamp	default
Hessian	Writes GDX version of current point - Jacobian and Hessian	<code>hessian.gdx</code>
Include	Start reading from a new file	
intervalEval	Include interval evaluations in Jacobian and Hessian	0
intervalEvalDebug	Turn on debug output for the interval evaluations	0
Jacobian	Writes GDX version of current point - Jacobian	<code>jacobian.gdx</code>
Match	Force a complete match for all MCP variable/equation pairs	
ObjVar	Name of objective variable	<code>GAMS index name, e.g. x1</code>
PermuteEqus	Random seed for permutation of equations (0: no permutation) (only with ConvertD and GAMS output)	0
PermuteVars	Random seed for permutation of variables (0: no permutation) (only with ConvertD and GAMS output)	0
Reform	Force reformulations	100
Terminate	Force GAMS to terminate after conversion	

5.14 Couenne

COIN-OR Couenne (Convex Over and Under Envelopes for Nonlinear Estimation) is an open-source solver for nonconvex mixed-integer nonlinear programming (MINLPs). The code has been developed originally in a cooperation of Carnegie Mellon University and IBM Research. The COIN-OR project leader for Couenne is Pietro Belotti, now with FICO, Ltd.

Couenne solves convex and nonconvex MINLPs by an LP based spatial branch-and-bound algorithm. The implementation extends [BONMIN](#) and [BONMINH](#) by routines to compute valid linear outer approximations for nonconvex problems and methods for bound tightening and branching on nonlinear variables. Couenne uses [IPOPT](#) and [IPOPTH](#) to solve NLP subproblems.

For more information on the algorithm we refer to [\[33\]](#) [\[32\]](#) and the [Couenne web site](#). Most of the Couenne documentation in this section is taken from the Couenne manual [\[31\]](#).

Couenne can handle mixed-integer nonlinear programming models which functions can be nonconvex, but should be twice continuously differentiable. Further, an algebraic description of the model needs to be available, which makes the use of some GAMS functions and user-specified external/extrinsic functions impossible. The Couenne link in GAMS supports continuous, binary, and integer variables, but no special ordered sets, semi-continuous or semi-integer variables.

5.14.1 Usage

The following statement can be used inside your GAMS program to specify using Couenne:

```
Option MINLP = COUENNE;      { or LP, RMIP, MIP, DNLP, NLP, RMINLP, QCP, RMIQCP, MIQCP, CNS }
```

The above statement should appear before the Solve statement. If Couenne was specified as the default solver during GAMS installation, the above statement is not necessary.

5.14.1.1 Specification of Options

A Couenne option file contains IPOPT, BONMIN, and Couenne options. For clarity, all BONMIN options should be preceded with the prefix `bonmin.` and all Couenne options should be preceded with the prefix `couenne..` All IPOPT and many BONMIN options are available in Couenne.

The scheme to [name option files](#) is the same as for all other GAMS solvers. The format of the option file is [the same as for IPOPT](#).

GAMS/Couenne understands currently the following GAMS parameters: [reslim](#) (time limit), [nodlim](#) (node limit), [cutoff](#), [optca](#) (absolute gap tolerance), and [optcr](#) (relative gap tolerance). Further, the option [threads](#) can be used to control the number of threads used in the [linear algebra routines of IPOPT](#).

5.14.2 List of Options

In the following we give a list of all options available for Couenne, including those for the underlying solvers Ipopt and Bonmin.

5.14.2.1 Couenne options

Option	Description	Default
2mir_cuts	Frequency k (in terms of nodes) for generating 2mir_cuts cuts in branch-and-cut.	0
aggressive_fbbt	Aggressive feasibility-based bound tightening (to use with NLP points)	yes
art_cutoff	Artificial cutoff	maxdouble
art_lower	Artificial lower bound	mindouble
boundtightening_print_level	Output level for bound tightening code in Couenne	0
branching_object	type of branching object for variable selection	var_obj
branching_print_level	Output level for braching code in Couenne	0
branch_conv_cuts	Apply convexification cuts before branching (for now only within strong branching)	yes
branch_fbbt	Apply bound tightening before branching	yes
branch_lp_clamp	Defines safe interval percentage for using LP point as a branching point.	0.2
branch_lp_clamp_cube	Defines safe interval percentage [0,0.5] for using LP point as a branching point.	0.2
branch_lp_clamp_div	Defines safe interval percentage [0,0.5] for using LP point as a branching point.	0.2
branch_lp_clamp_exp	Defines safe interval percentage [0,0.5] for using LP point as a branching point.	0.2
branch_lp_clamp_log	Defines safe interval percentage [0,0.5] for using LP point as a branching point.	0.2
branch_lp_clamp_negpow	Defines safe interval percentage [0,0.5] for using LP point as a branching point.	0.2
branch_lp_clamp_pow	Defines safe interval percentage [0,0.5] for using LP point as a branching point.	0.2
branch_lp_clamp_prod	Defines safe interval percentage [0,0.5] for using LP point as a branching point.	0.2
branch_lp_clamp_sqr	Defines safe interval percentage [0,0.5] for using LP point as a branching point.	0.2
branch_lp_clamp_trig	Defines safe interval percentage [0,0.5] for using LP point as a branching point.	0.2
branch_midpoint_alpha	Defines convex combination of mid point and current LP point: $b = \alpha x_{lp} + (1-\alpha)(lb+ub)/2$.	0.25

Option	Description	Default
branch_pt_select	Chooses branching point selection strategy	mid-point
branch_pt_select_cube	Chooses branching point selection strategy for operator cube.	common
branch_pt_select_div	Chooses branching point selection strategy for operator div.	common
branch_pt_select_exp	Chooses branching point selection strategy for operator exp.	common
branch_pt_select_log	Chooses branching point selection strategy for operator log.	common
branch_pt_select_negpow	Chooses branching point selection strategy for operator negpow.	common
branch_pt_select_pow	Chooses branching point selection strategy for operator pow.	common
branch_pt_select_prod	Chooses branching point selection strategy for operator prod.	common
branch_pt_select_sqr	Chooses branching point selection strategy for operator sqr.	common
branch_pt_select_trig	Chooses branching point selection strategy for operator trig.	common
check_lp	Check all LPs through an independent call to OsiClpSolverInterface::initialSolve()	no
clique_cuts	Frequency k (in terms of nodes) for generating clique_cuts cuts in branch-and-cut.	0
cont_var_priority	Priority of continuous variable branching	99
convexification_cuts	Specify the frequency (in terms of nodes) at which couenne ecp cuts are generated.	1
convexification_points	Specify the number of points at which to convexify when convexification type is uniform-grid or around-current-point.	4
convexification_type	Determines in which point the linear over/under-estimator are generated	current-point-only
convexifying_print_level	Output level for convexifying code in Couenne	0
cover_cuts	Frequency k (in terms of nodes) for generating cover_cuts cuts in branch-and-cut.	0
crossconv_cuts	The frequency (in terms of nodes) at which Couenne cross-aux convexification cuts are generated.	0
delete_redundant	Eliminate redundant variables, which appear in the problem as $x.k = x.h$	yes
disjcuts_print_level	Output level for disjunctive cuts in Couenne	0
disj_active_cols	Only include violated variable bounds in the Cut Generating LP (CGLP).	no
disj_active_rows	Only include violated linear inequalities in the CGLP.	no

Option	Description	Default
<code>disj_cumulative</code>	Add previous disjunctive cut to current CGLP.	no
<code>disj_depth_level</code>	Depth of the B&B tree when to start decreasing the number of objects that generate disjunctions.	5
<code>disj_depth_stop</code>	Depth of the B&B tree where separation of disjunctive cuts is stopped.	20
<code>disj_init_number</code>	Maximum number of disjunction to consider at each iteration.	10
<code>disj_init_perc</code>	The maximum fraction of all disjunctions currently violated by the problem to consider for generating disjunctions.	0.5
<code>enable_lp_implied_bounds</code>	Enable <code>OsiSolverInterface::tightenBounds()</code> – warning: it has caused some trouble to Couenne	no
<code>enable_sos</code>	Use Special Ordered Sets (SOS) as indicated in the MINLP model	no
<code>estimate_select</code>	How the min/max estimates of the subproblems' bounds are used in strong branching	normal
<code>feasibility_bt</code>	Feasibility-based (cheap) bound tightening (FBBT)	yes
<code>feas_pump_convcuts</code>	Separate MILP-feasible, MINLP-infeasible solution during or after MILP solver.	none
<code>feas_pump_fademult</code>	decrease/increase rate of multipliers	1
<code>feas_pump_heuristic</code>	Apply the nonconvex Feasibility Pump	no
<code>feas_pump_iter</code>	Number of iterations in the main Feasibility Pump loop	10
<code>feas_pump_level</code>	Specify the logarithm of the number of feasibility pumps to perform on average for each level of given depth of the tree.	3
<code>feas_pump_milpmethod</code>	How should the integral solution be constructed?	0
<code>feas_pump_mult_dist_milp</code>	Weight of the distance in the distance function of the milp problem	0
<code>feas_pump_mult_dist_nlp</code>	Weight of the distance in the distance function of the nlp problem	0
<code>feas_pump_mult_hess_milp</code>	Weight of the Hessian in the distance function of the milp problem	0
<code>feas_pump_mult_hess_nlp</code>	Weight of the Hessian in the distance function of the nlp problem	0
<code>feas_pump_mult_objf_milp</code>	Weight of the original objective function in the distance function of the milp problem	0
<code>feas_pump_mult_objf_nlp</code>	Weight of the original objective function in the distance function of the nlp problem	0
<code>feas_pump_nseprounds</code>	Number of rounds of convexification cuts.	4

Option	Description	Default
<code>feas_pump_poolcomp</code>	Priority field to compare solutions in FP pool	4
<code>feas_pump_tabumgt</code>	Retrieval of MILP solutions when the one returned is unsatisfactory	pool
<code>feas_pump_usescip</code>	Should SCIP be used to solve the MILPs?	yes
<code>feas_pump_vardist</code>	Distance computed on integer-only or on both types of variables, in different flavors.	integer
<code>feas_tolerance</code>	Tolerance for constraints/auxiliary variables	1e-05
<code>fixpoint_bt</code>	The frequency (in terms of nodes) at which Fix Point Bound Tightening is performed.	0
<code>fixpoint_bt_model</code>	Choose whether to add an extended fixpoint LP model or a more compact one.	compact
<code>flow_covers_cuts</code>	Frequency k (in terms of nodes) for generating <code>flow_covers_cuts</code> cuts in branch-and-cut.	0
<code>Gomory_cuts</code>	Frequency k (in terms of nodes) for generating Gomory_cuts cuts in branch-and-cut.	0
<code>int_var_priority</code>	Priority of integer variable branching	98
<code>iterative_rounding_aggressiveness</code>	Aggressiveness of the Iterative Rounding heuristic	1
<code>iterative_rounding_base_lbrhs</code>	Base rhs of the local branching constraint for Iterative Rounding	15
<code>iterative_rounding_heuristic</code>	Do we use the Iterative Rounding heuristic	no
<code>iterative_rounding_num_fir_points</code>	Max number of points rounded at the beginning of Iterative Rounding	5
<code>iterative_rounding_omega</code>	Omega parameter of the Iterative Rounding heuristic	0.2
<code>iterative_rounding_time</code>	Specify the maximum time allowed for the Iterative Rounding heuristic	-1
<code>iterative_rounding_time_firstcall</code>	Specify the maximum time allowed for the Iterative Rounding heuristic when no feasible solution is known	-1
<code>lift_and_project_cuts</code>	Frequency k (in terms of nodes) for generating <code>lift_and_project_cuts</code> cuts in branch-and-cut.	0
<code>local_branching_heuristic</code>	Apply local branching heuristic	no
<code>local_optimization_heuristic</code>	Search for local solutions of MINLPs	yes
<code>log_num_abt_per_level</code>	Specify the frequency (in terms of nodes) for aggressive bound tightening.	2
<code>log_num_local_optimization_per_level</code>	Specify the logarithm of the number of local optimizations to perform on average for each level of given depth of the tree.	2

Option	Description	Default
<code>log_num_obbt_per_level</code>	Specify the frequency (in terms of nodes) for optimality-based bound tightening.	1
<code>max_fbbt_iter</code>	Number of FBBT iterations before stopping even with tightened bounds.	3
<code>minlp_disj_cuts</code>	The frequency (in terms of nodes) at which Couenne disjunctive cuts are generated.	0
<code>mir_cuts</code>	Frequency k (in terms of nodes) for generating mir_cuts cuts in branch-and-cut.	0
<code>multilinear_separation</code>	Separation for multilinear terms	tight
<code>nlpheur_print_level</code>	Output level for NLP heuristic in Couenne	0
<code>optimality_bt</code>	Optimality-based (expensive) bound tightening (OBBT)	yes
<code>orbital_branching</code>	detect symmetries and apply orbital branching	no
<code>orbital_branching_depth</code>	Maximum depth at which the symmetry group is computed	10
<code>output_level</code>	Output level	4
<code>probing_cuts</code>	Frequency k (in terms of nodes) for generating probing_cuts cuts in branch-and-cut.	0
<code>problem_print_level</code>	Output level for problem manipulation code in Couenne	2
<code>pseudocost_mult</code>	Multipliers of pseudocosts for estimating and update estimation of bound	interval_br_rev
<code>pseudocost_mult_lp</code>	Use distance between LP points to update multipliers of pseudocosts after simulating branching	no
<code>quadrilinear_decomp</code>	type of decomposition for quadrilinear terms (see work by Cafieri, Lee, Liberti)	rAI
<code>redcost_bt</code>	Reduced cost bound tightening	yes
<code>reduce_split_cuts</code>	Frequency k (in terms of nodes) for generating reduce_split_cuts cuts in branch-and-cut.	0
<code>red_cost_branching</code>	Apply Reduced Cost Branching (instead of the Violation Transfer) – MUST have vt_obj enabled	no
<code>reformulate_print_level</code>	Output level for reformulating problems in Couenne	0
<code>sdp_cuts</code>	The frequency (in terms of nodes) at which Couenne SDP cuts are generated.	0
<code>sdp_cuts_fillmissing</code>	Create fictitious auxiliary variables to fill non-fully dense minors. Can make a difference when Q has at least one zero term.	no
<code>sdp_cuts_neg_ev</code>	Only use negative eigenvalues to create sdp cuts.	yes

Option	Description	Default
sdp_cuts_num_ev	The number of eigenvectors of matrix X to be used to create sdp cuts.	-1
sdp_cuts_sparsify	Make cuts sparse by greedily reducing X one column at a time before extracting eigenvectors.	no
solvetrace	Name of file for writing solving progress information.	
solvetracenodefreq	Frequency in number of nodes for writing solving progress information.	100
solvetracetimefreq	Frequency in seconds for writing solving progress information.	5
trust_strong	Fathom strong branching LPs when their bound is above the cutoff	yes
twoimpl_depth_level	Depth of the B&B tree when to start decreasing the chance of running this algorithm.	5
twoimpl_depth_stop	Depth of the B&B tree where separation is stopped.	20
two_implied_bt	The frequency (in terms of nodes) at which Couenne two-implied bounds are tightened.	0
two_implied_max_trials	The number of iteration at each call to the cut generator.	2
use_auxcons	Use constraints-defined auxiliaries, i.e. auxiliaries $w = f(x)$ defined by original constraints $f(x) - w = 0$	yes
use_quadratic	Use quadratic expressions and related <code>exprQuad</code> class	no
use_semiaux	Use semiauxiliaries, i.e. auxiliaries defined as $w \geq f(x)$ rather than $w := f(x)$	yes
violated_cuts_only	Yes if only violated convexification cuts should be added	yes

5.14.2.2 Bonmin Branch-and-bound options

Option	Description	Default
allowable_fraction_gap	Specify the value of relative gap under which the algorithm stops.	0.1
allowable_gap	Specify the value of absolute gap under which the algorithm stops.	0
clocktype	Type of clock to use for time_limit	wall
cutoff	Specify cutoff value.	1e+100
cutoff_decr	Specify cutoff decrement.	1e-05
enable_dynamic_nlp	Enable dynamic linear and quadratic rows addition in nlp	no
integer_tolerance	Set integer tolerance.	1e-06
iteration_limit	Set the cumulative maximum number of iteration in the algorithm used to process nodes continuous relaxations in the branch-and-bound.	maxint

Option	Description	Default
nlp_failure_behavior	Set the behavior when an NLP or a series of NLP are unsolved by Ipopt (we call unsolved an NLP for which Ipopt is not able to guarantee optimality within the specified tolerances).	stop
node_comparison	Choose the node selection strategy.	best-bound
node_limit	Set the maximum number of nodes explored in the branch-and-bound search.	maxint
number_before_trust	Set the number of branches on a variable before its pseudo costs are to be believed in dynamic strong branching.	8
number_strong_branch	Choose the maximum number of variables considered for strong branching.	20
num_cut_passes	Set the maximum number of cut passes at regular nodes of the branch-and-cut.	1
num_cut_passes_at_root	Set the maximum number of cut passes at regular nodes of the branch-and-cut.	20
random_generator_seed	Set seed for random number generator (a value of -1 sets seeds to time since Epoch).	0
read_solution_file	Read a file with the optimal solution to test if algorithms cuts it.	no
solution_limit	Abort after that much integer feasible solution have been found by algorithm	maxint
time_limit	Set the global maximum computation time (in secs) for the algorithm.	1000
tree_search_strategy	Pick a strategy for traversing the tree	probed-dive
variable_selection	Chooses variable selection strategy	strong-branching

5.14.2.3 Bonmin NLP interface

Option	Description	Default
warm_start	Select the warm start method	none

5.14.2.4 Bonmin NLP solution robustness

Option	Description	Default
max_consecutive_failures	(temporarily removed) Number n of consecutive unsolved problems before aborting a branch of the tree.	10
max_random_point_radius	Set max value r for coordinate of a random point.	100000
num_iterations_suspect	Number of iterations over which a node is considered 'suspect' (for debugging purposes only, see detailed documentation).	-1
num_retry_unsolved_random_point	Number k of times that the algorithm will try to resolve an unsolved NLP with a random starting point (we call unsolved an NLP for which Ipopt is not able to guarantee optimality within the specified tolerances).	0

Option	Description	Default
random_point_perturbation_interval	Amount by which starting point is perturbed when choosing to pick random point by perturbing starting point	1
random_point_type	method to choose a random starting point	Jon
resolve_on_small_infeasibility	If a locally infeasible problem is infeasible by less than this, resolve it with initial starting point.	0

5.14.2.5 Bonmin Nonconvex problems

Option	Description	Default
coeff_var_threshold	Coefficient of variation threshold (for dynamic definition of cutoff_decr).	0.1
dynamic_def_cutoff_decr	Do you want to define the parameter cutoff_decr dynamically?	no
first_perc_for_cutoff_decr	The percentage used when, the coeff of variance is smaller than the threshold, to compute the cutoff_decr dynamically.	-0.02
max_consecutive_infeasible	Number of consecutive infeasible subproblems before aborting a branch.	0
num_resolve_at_infeasibles	Number k of tries to resolve an infeasible node (other than the root) of the tree with different starting point.	0
num_resolve_at_node	Number k of tries to resolve a node (other than the root) of the tree with different starting point.	0
num_resolve_at_root	Number k of tries to resolve the root node with different starting points.	0
second_perc_for_cutoff_decr	The percentage used when, the coeff of variance is greater than the threshold, to compute the cutoff_decr dynamically.	-0.05

5.14.2.6 Bonmin Outer Approximation cuts generation

Option	Description	Default
add_only_violated_oa	Do we add all OA cuts or only the ones violated by current point?	no
oa_cuts_scope	Specify if OA cuts added are to be set globally or locally valid	global
oa_rhs_relax	Value by which to relax OA cut	1e-08
tiny_element	Value for tiny element in OA cut	1e-08
very_tiny_element	Value for very tiny element in OA cut	1e-17

5.14.2.7 Bonmin Output and Loglevel

Option	Description	Default
bb_log_interval	Interval at which node level output is printed.	100
bb_log_level	specify main branch-and-bound log level.	1
lp_log_level	specify LP log level.	0

Option	Description	Default
nlp_log_at_root	specify a different log level for root relaxation.	0
nlp_log_level	specify NLP solver interface log level (independent from ipopt print_level).	1
oa_cuts_log_level	level of log when generating OA cuts.	0

5.14.2.8 Bonmin Primal Heuristics

Option	Description	Default
algorithm	Choice of the algorithm.	B-BB
feasibility_pump_objective_norm	Norm of feasibility pump objective function	1
heuristic_dive_fractional	if yes runs the Dive Fractional heuristic	no
heuristic_dive_MIP_fractional	if yes runs the Dive MIP Fractional heuristic	no
heuristic_dive_MIP_vectorLength	if yes runs the Dive MIP VectorLength heuristic	no
heuristic_dive_vectorLength	if yes runs the Dive VectorLength heuristic	no
heuristic_feasibility_pump	whether the heuristic feasibility pump should be used	no
heuristic_RINS	if yes runs the RINS heuristic	no
milp_solver	Choose the subsolver to solve MILP sub-problems in OA decompositions.	Cbc_D
milp_strategy	Choose a strategy for MILPs.	find_good_sol
pump_for_minlp	whether to run the feasibility pump heuristic for MINLP	no

5.14.2.9 Bonmin Strong branching setup

Option	Description	Default
candidate_sort_criterion	Choice of the criterion to choose candidates in strong-branching	best-ps-cost
maxmin_crit_have_sol	Weight towards minimum in of lower and upper branching estimates when a solution has been found.	0.1
maxmin_crit_no_sol	Weight towards minimum in of lower and upper branching estimates when no solution has been found yet.	0.7
min_number_strong_branch	Sets minimum number of variables for strong branching (overriding trust)	0
number_before_trust_list	Set the number of branches on a variable before its pseudo costs are to be believed during setup of strong branching candidate list.	0
number_look_ahead	Sets limit of look-ahead strong-branching trials	0
number_strong_branch_root	Maximum number of variables considered for strong branching in root node.	maxint

Option	Description	Default
<code>setup_pseudo_frac</code>	Proportion of strong branching list that has to be taken from most-integer-infeasible list.	0.5
<code>trust_strong_branching_for_pseudo_cost</code>	Whether or not to trust strong branching results for updating pseudo costs.	yes

5.14.2.10 Ipopt Barrier Parameter Update

Option	Description	Default
<code>adaptive_mu_globalization</code>	Globalization strategy for the adaptive mu selection mode.	<code>obj-constr-filter</code>
<code>adaptive_mu_kkterror_red_fact</code>	Sufficient decrease factor for 'kkt-error' globalization strategy.	0.9999
<code>adaptive_mu_kkterror_red_iters</code>	Maximum number of iterations requiring sufficient progress.	4
<code>adaptive_mu_kkt_norm_type</code>	Norm used for the KKT error in the adaptive mu globalization strategies.	<code>2-norm-squared</code>
<code>adaptive_mu_monotone_init_factor</code>	Determines the initial value of the barrier parameter when switching to the monotone mode.	0.8
<code>adaptive_mu_restore_previous_iterate</code>	Indicates if the previous iterate should be restored if the monotone mode is entered.	no
<code>barrier_tol_factor</code>	Factor for mu in barrier stop test.	10
<code>filter_margin_fact</code>	Factor determining width of margin for <code>obj-constr-filter</code> adaptive globalization strategy.	<code>1e-05</code>
<code>filter_max_margin</code>	Maximum width of margin in <code>obj-constr-filter</code> adaptive globalization strategy.	1
<code>fixed_mu_oracle</code>	Oracle for the barrier parameter when switching to fixed mode.	<code>average_compl</code>
<code>mu_allow_fast_monotone_decrease</code>	Allow skipping of barrier problem if barrier test is already met.	yes
<code>mu_init</code>	Initial value for the barrier parameter.	0.1
<code>mu_linear_decrease_factor</code>	Determines linear decrease rate of barrier parameter.	0.2
<code>mu_max</code>	Maximum value for barrier parameter.	100000
<code>mu_max_fact</code>	Factor for initialization of maximum value for barrier parameter.	1000
<code>mu_min</code>	Minimum value for barrier parameter.	<code>1e-11</code>
<code>mu_oracle</code>	Oracle for a new barrier parameter in the adaptive strategy.	<code>quality-function</code>
<code>mu_strategy</code>	Update strategy for barrier parameter.	<code>monotone</code>
<code>mu_superlinear_decrease_power</code>	Determines superlinear decrease rate of barrier parameter.	1.5
<code>quality_function_balancing_term</code>	The balancing term included in the quality function for centrality.	none
<code>quality_function_centrality</code>	The penalty term for centrality that is included in quality function.	none

Option	Description	Default
quality_function_max_section_steps	Maximum number of search steps during direct search procedure determining the optimal centering parameter.	8
quality_function_norm_type	Norm used for components of the quality function.	2-norm-squared
quality_function_section_qf_tol	Tolerance for the golden section search procedure determining the optimal centering parameter (in the function value space).	0
quality_function_section_sigma_tol	Tolerance for the section search procedure determining the optimal centering parameter (in sigma space).	0.01
sigma_max	Maximum value of the centering parameter.	100
sigma_min	Minimum value of the centering parameter.	1e-06
tau_min	Lower bound on fraction-to-the-boundary parameter tau.	0.99

5.14.2.11 Ipopt Convergence

Option	Description	Default
acceptable_compl_inf_tol	'Acceptance' threshold for the complementarity conditions.	0.01
acceptable_constr_viol_tol	'Acceptance' threshold for the constraint violation.	0.01
acceptable_dual_inf_tol	'Acceptance' threshold for the dual infeasibility.	1e+10
acceptable_iter	Number of 'acceptable' iterates before triggering termination.	15
acceptable_obj_change_tol	'Acceptance' stopping criterion based on objective function change.	1e+20
acceptable_tol	'Acceptable' convergence tolerance (relative).	1e-06
compl_inf_tol	Desired threshold for the complementarity conditions.	0.0001
constr_viol_tol	Desired threshold for the constraint violation.	0.0001
diverging_iterates_tol	Threshold for maximal value of primal iterates.	1e+20
dual_inf_tol	Desired threshold for the dual infeasibility.	1
max_cpu_time	Maximum number of CPU seconds.	1e+06
max_iter	Maximum number of iterations.	3000
mu_target	Desired value of complementarity.	0
s_max	Scaling threshold for the NLP error.	100
tol	Desired convergence tolerance (relative).	1e-08

5.14.2.12 Ipopt Hessian Approximation

Option	Description	Default
hessian_approximation	Indicates what Hessian information is to be used.	exact
hessian_approximation_space	Indicates in which subspace the Hessian information is to be approximated.	nonlinear-variables
limited_memory_aug_solver	Strategy for solving the augmented system for low-rank Hessian.	sherman-morrison
limited_memory_initialization	Initialization strategy for the limited memory quasi-Newton approximation.	scalar1
limited_memory_init_val	Value for B0 in low-rank update.	1
limited_memory_init_val_max	Upper bound on value for B0 in low-rank update.	1e+08
limited_memory_init_val_min	Lower bound on value for B0 in low-rank update.	1e-08
limited_memory_max_history	Maximum size of the history for the limited quasi-Newton Hessian approximation.	6
limited_memory_max_skipping	Threshold for successive iterations where update is skipped.	2
limited_memory_special_for_resto	Determines if the quasi-Newton updates should be special during the restoration phase.	no
limited_memory_update_type	Quasi-Newton update formula for the limited memory approximation.	bfgs

5.14.2.13 Ipopt Initialization

Option	Description	Default
bound_frac	Desired minimum relative distance from the initial point to bound.	0.01
bound_mult_init_method	Initialization method for bound multipliers	constant
bound_mult_init_val	Initial value for the bound multipliers.	1
bound_push	Desired minimum absolute distance from the initial point to bound.	0.01
constr_mult_init_max	Maximum allowed least-square guess of constraint multipliers.	1000
least_square_init_duals	Least square initialization of all dual variables	no
least_square_init_primal	Least square initialization of the primal variables	no
slack_bound_frac	Desired minimum relative distance from the initial slack to bound.	0.01
slack_bound_push	Desired minimum absolute distance from the initial slack to bound.	0.01

5.14.2.14 Ipopt Line Search

Option	Description	Default
accept_after_max_steps	Accept a trial point after maximal this number of steps.	-1

Option	Description	Default
<code>accept_every_trial_step</code>	Always accept the first trial step.	<code>no</code>
<code>alpha_for_y</code>	Method to determine the step size for constraint multipliers.	<code>primal</code>
<code>alpha_for_y_tol</code>	Tolerance for switching to full equality multiplier steps.	<code>10</code>
<code>alpha_min_frac</code>	Safety factor for the minimal step size (before switching to restoration phase).	<code>0.05</code>
<code>alpha_red_factor</code>	Fractional reduction of the trial step size in the backtracking line search.	<code>0.5</code>
<code>constraint_violation_norm_type</code>	Norm to be used for the constraint violation in the line search.	<code>1-norm</code>
<code>corrector_compl_avrg_red_fact</code>	Complementarity tolerance factor for accepting corrector step.	<code>1</code>
<code>corrector_type</code>	The type of corrector steps that should be taken.	<code>none</code>
<code>delta</code>	Multiplier for constraint violation in the switching rule.	<code>1</code>
<code>eta_phi</code>	Relaxation factor in the Armijo condition.	<code>1e-08</code>
<code>filter_reset_trigger</code>	Number of iterations that trigger the filter reset.	<code>5</code>
<code>gamma_phi</code>	Relaxation factor in the filter margin for the barrier function.	<code>1e-08</code>
<code>gamma_theta</code>	Relaxation factor in the filter margin for the constraint violation.	<code>1e-05</code>
<code>kappa_sigma</code>	Factor limiting the deviation of dual variables from primal estimates.	<code>1e+10</code>
<code>kappa_soc</code>	Factor in the sufficient reduction rule for second order correction.	<code>0.99</code>
<code>line_search_method</code>	Globalization method used in backtracking line search	<code>filter</code>
<code>max_filter_resets</code>	Maximal allowed number of filter resets	<code>5</code>
<code>max_soc</code>	Maximum number of second order correction trial steps at each iteration.	<code>4</code>
<code>nu_inc</code>	Increment of the penalty parameter.	<code>0.0001</code>
<code>nu_init</code>	Initial value of the penalty parameter.	<code>1e-06</code>
<code>obj_max_inc</code>	Determines the upper bound on the acceptable increase of barrier objective function.	<code>5</code>
<code>recalc_y</code>	Tells the algorithm to recalculate the equality and inequality multipliers as least square estimates.	<code>no</code>
<code>recalc_y_feas_tol</code>	Feasibility threshold for recomputation of multipliers.	<code>1e-06</code>
<code>rho</code>	Value in penalty parameter update formula.	<code>0.1</code>
<code>skip_corr_if_neg_curv</code>	Skip the corrector step in negative curvature iteration.	<code>yes</code>
<code>skip_corr_in_monotone_mode</code>	Skip the corrector step during monotone barrier parameter mode.	<code>yes</code>
<code>slack_move</code>	Correction size for very small slacks.	<code>1.81899e-12</code>
<code>soc_method</code>	Ways to apply second order correction	<code>0</code>

Option	Description	Default
s_phi	Exponent for linear barrier function model in the switching rule.	2.3
s_theta	Exponent for current constraint violation in the switching rule.	1.1
theta_max_fact	Determines upper bound for constraint violation in the filter.	10000
theta_min_fact	Determines constraint violation threshold in the switching rule.	0.0001
tiny_step_tol	Tolerance for detecting numerically insignificant steps.	2.22045e-15
tiny_step_y_tol	Tolerance for quitting because of numerically insignificant steps.	0.01
watchdog_shortened_iter_trigger	Number of shortened iterations that trigger the watchdog.	10
watchdog_trial_iter_max	Maximum number of watchdog iterations.	3

5.14.2.15 Ipopt Linear Solver

Option	Description	Default
linear_scaling_on_demand	Flag indicating that linear scaling is only done if it seems required.	yes
linear_solver	Linear solver used for step computations.	ma27
linear_system_scaling	Method for scaling the linear system.	mc19

5.14.2.16 Ipopt MA27 Linear Solver

Option	Description	Default
ma27_ignore_singularity	Enables MA27's ability to solve a linear system even if the matrix is singular.	no
ma27_la_init_factor	Real workspace memory for MA27.	5
ma27_liw_init_factor	Integer workspace memory for MA27.	5
ma27_meminc_factor	Increment factor for workspace size for MA27.	2
ma27_pivtol	Pivot tolerance for the linear solver MA27.	1e-08
ma27_pivtolmax	Maximum pivot tolerance for the linear solver MA27.	0.0001
ma27_skip_inertia_check	Always pretend inertia is correct.	no

5.14.2.17 Ipopt MA28 Linear Solver

Option	Description	Default
ma28_pivtol	Pivot tolerance for linear solver MA28.	0.01

5.14.2.18 Ipopt MA57 Linear Solver

Option	Description	Default
ma57_automatic_scaling	Controls MA57 automatic scaling	no
ma57_block_size	Controls block size used by Level 3 BLAS in MA57BD	16
ma57_node_amalgamation	Node amalgamation parameter	16
ma57_pivot_order	Controls pivot order in MA57	5
ma57_pivtol	Pivot tolerance for the linear solver MA57.	1e-08
ma57_pivtolmax	Maximum pivot tolerance for the linear solver MA57.	0.0001
ma57_pre_alloc	Safety factor for work space memory allocation for the linear solver MA57.	1.05
ma57_small_pivot_flag	If set to 1, then when small entries defined by CNTL(2) are detected they are removed and the corresponding pivots placed at the end of the factorization. This can be particularly efficient if the matrix is highly rank deficient.	0

5.14.2.19 Ipopt MA77 Linear Solver

Option	Description	Default
ma77_buffer_lpage	Number of scalars per MA77 buffer page	4096
ma77_buffer_npage	Number of pages that make up MA77 buffer	1600
ma77_file_size	Target size of each temporary file for MA77, scalars per type	2097152
ma77_maxstore	Maximum storage size for MA77 in-core mode	0
ma77_nemin	Node Amalgamation parameter	8
ma77_order	Controls type of ordering used by HSL_MA77	metis
ma77_print_level	Debug printing level for the linear solver MA77	-1
ma77_small	Zero Pivot Threshold	1e-20
ma77_static	Static Pivoting Threshold	0
ma77_u	Pivoting Threshold	1e-08
ma77_umax	Maximum Pivoting Threshold	0.0001

5.14.2.20 Ipopt MA86 Linear Solver

Option	Description	Default
ma86_nemin	Node Amalgamation parameter	32
ma86_order	Controls type of ordering used by HSL_MA86	auto
ma86_print_level	Debug printing level for the linear solver MA86	-1
ma86_scaling	Controls scaling of matrix	mc64

Option	Description	Default
ma86_small	Zero Pivot Threshold	1e-20
ma86_static	Static Pivoting Threshold	0
ma86_u	Pivoting Threshold	1e-08
ma86_umax	Maximum Pivoting Threshold	0.0001

5.14.2.21 Ipopt MA97 Linear Solver

Option	Description	Default
ma97_nemin	Node Amalgamation parameter	8
ma97_order	Controls type of ordering used by HSL_MA97	auto
ma97_print_level	Debug printing level for the linear solver MA97	0
ma97_scaling	Specifies strategy for scaling in HSL_MA97 linear solver	dynamic
ma97_scaling1	First scaling.	mc64
ma97_scaling2	Second scaling.	mc64
ma97_scaling3	Third scaling.	mc64
ma97_small	Zero Pivot Threshold	1e-20
ma97_solve_blas3	Controls if blas2 or blas3 routines are used for solve	no
ma97_switch1	First switch, determine when ma97_scaling1 is enabled.	od_hd_reuse
ma97_switch2	Second switch, determine when ma97_scaling2 is enabled.	never
ma97_switch3	Third switch, determine when ma97_scaling3 is enabled.	never
ma97_u	Pivoting Threshold	1e-08
ma97_umax	Maximum Pivoting Threshold	0.0001

5.14.2.22 Ipopt Mumps Linear Solver

Option	Description	Default
mumps_dep_tol	Pivot threshold for detection of linearly dependent constraints in MUMPS.	0
mumps_mem_percent	Percentage increase in the estimated working space for MUMPS.	1000
mumps_permuting_scaling	Controls permuting and scaling in MUMPS	7
mumps_pivot_order	Controls pivot order in MUMPS	7
mumps_pivtol	Pivot tolerance for the linear solver MUMPS.	1e-06
mumps_pivtolmax	Maximum pivot tolerance for the linear solver MUMPS.	0.1
mumps_scaling	Controls scaling in MUMPS	77

5.14.2.23 Ipopt NLP

Option	Description	Default
bound_relax_factor	Factor for initial relaxation of the bounds.	1e-10
check_derivatives_for_naninf	Indicates whether it is desired to check for Nan/Inf in derivative matrices	no
dependency_detection_with_rhs	Indicates if the right hand sides of the constraints should be considered during dependency detection	no
dependency_detector	Indicates which linear solver should be used to detect linearly dependent equality constraints.	none
fixed_variable_treatment	Determines how fixed variables should be handled.	make_parameter
honor_original_bounds	Indicates whether final points should be projected into original bounds.	yes
jac_c_constant	Indicates whether all equality constraints are linear	no
jac_d_constant	Indicates whether all inequality constraints are linear	no
kappa_d	Weight for linear damping term (to handle one-sided bounds).	1e-05

5.14.2.24 Ipopt NLP Scaling

Option	Description	Default
nlp_scaling_constr_target_gradient	Target value for constraint function gradient size.	0
nlp_scaling_max_gradient	Maximum gradient after NLP scaling.	100
nlp_scaling_method	Select the technique used for scaling the NLP.	gradient-based
nlp_scaling_min_value	Minimum value of gradient-based scaling values.	1e-08
nlp_scaling_obj_target_gradient	Target value for objective function gradient size.	0

5.14.2.25 Ipopt Output

Option	Description	Default
inf_pr_output	Determines what value is printed in the 'inf_pr' output column.	original
print_eval_error	Switch to enable printing information about function evaluation errors into the GAMS listing file.	yes
print_frequency_iter	Determines at which iteration frequency the summarizing iteration output line should be printed.	1
print_frequency_time	Determines at which time frequency the summarizing iteration output line should be printed.	0
print_info_string	Enables printing of additional info string at end of iteration output.	no
print_level	Output verbosity level.	5
print_timing_statistics	Switch to print timing statistics.	no

Option	Description	Default
replace_bounds	Indicates if all variable bounds should be replaced by inequality constraints	no

5.14.2.26 Ipopt Pardiso Linear Solver

Option	Description	Default
pardiso_matching_strategy	Matching strategy to be used by Pardiso	complete+2x2
pardiso_max_iterative_refinement_steps	Limit on number of iterative refinement steps.	1
pardiso_msglvl	Pardiso message level	0
pardiso_order	Controls the fill-in reduction ordering algorithm for the input matrix.	metis
pardiso_redo_symbolic_fact_only_if_inertia_wrong	Toggle for handling case when elements were perturbed by Pardiso.	no
pardiso_repeated_perturbation_means_singular	Interpretation of perturbed elements.	no
pardiso_skip_inertia_check	Always pretend inertia is correct.	no

5.14.2.27 Ipopt Restoration Phase

Option	Description	Default
bound_mult_reset_threshold	Threshold for resetting bound multipliers after the restoration phase.	1000
constr_mult_reset_threshold	Threshold for resetting equality and inequality multipliers after restoration phase.	0
evaluate_orig_obj_at_resto_trial	Determines if the original objective function should be evaluated at restoration phase trial points.	yes
expect_infeasible_problem	Enable heuristics to quickly detect an infeasible problem.	no
expect_infeasible_problem_ctol	Threshold for disabling 'expect_infeasible_problem' option.	0.001
expect_infeasible_problem_ytol	Multiplier threshold for activating 'expect_infeasible_problem' option.	1e+08
max_resto_iter	Maximum number of successive iterations in restoration phase.	3000000
max_soft_resto_iters	Maximum number of iterations performed successively in soft restoration phase.	10
required_infeasibility_reduction	Required reduction of infeasibility before leaving restoration phase.	0.9
resto_failure_feasibility_threshold	Threshold for primal infeasibility to declare failure of restoration phase.	0
resto_penalty_parameter	Penalty parameter in the restoration phase objective function.	1000
resto_proximity_weight	Weighting factor for the proximity term in restoration phase objective.	1
soft_resto_pderror_reduction_factor	Required reduction in primal-dual error in the soft restoration phase.	0.9999
start_with_resto	Tells algorithm to switch to restoration phase in first iteration.	no

5.14.2.28 Ipopt Step Calculation

Option	Description	Default
fast_step_computation	Indicates if the linear system should be solved quickly.	no
first_hessian_perturbation	Size of first x-s perturbation tried.	0.0001
jacobian_regularization_exponent	Exponent for mu in the regularization for rank-deficient constraint Jacobians.	0.25
jacobian_regularization_value	Size of the regularization for rank-deficient constraint Jacobians.	1e-08
max_hessian_perturbation	Maximum value of regularization parameter for handling negative curvature.	1e+20
max_refinement_steps	Maximum number of iterative refinement steps per linear system solve.	10
mehrotra_algorithm	Indicates if we want to do Mehrotra's algorithm.	no
min_hessian_perturbation	Smallest perturbation of the Hessian block.	1e-20
min_refinement_steps	Minimum number of iterative refinement steps per linear system solve.	1
neg_curv_test_reg	Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014).	yes
neg_curv_test_tol	Tolerance for heuristic to ignore wrong inertia.	0
perturb_always_cd	Active permanent perturbation of constraint linearization.	no
perturb_dec_fact	Decrease factor for x-s perturbation.	0.333333
perturb_inc_fact	Increase factor for x-s perturbation.	8
perturb_inc_fact_first	Increase factor for x-s perturbation for very first perturbation.	100
residual_improvement_factor	Minimal required reduction of residual test ratio in iterative refinement.	1
residual_ratio_max	Iterative refinement tolerance	1e-10
residual_ratio_singular	Threshold for declaring linear system singular after failed iterative refinement.	1e-05

5.14.2.29 Ipopt Warm Start

Option	Description	Default
warm_start_bound_frac	same as bound_frac for the regular initializer.	0.001
warm_start_bound_push	same as bound_push for the regular initializer.	0.001
warm_start_init_point	Warm-start for initial point	no
warm_start_mult_bound_push	same as mult_bound_push for the regular initializer.	0.001
warm_start_mult_init_max	Maximum initial value for the equality multipliers.	1e+06
warm_start_slack_bound_frac	same as slack_bound_frac for the regular initializer.	0.001
warm_start_slack_bound_push	same as slack_bound_push for the regular initializer.	0.001

5.14.3 Detailed Options Description

In the following we give a detailed list of options available for Couenne, including those for the underlying Ipopt and Bonmin solvers.

2mir_cuts (*integer*): Frequency k (in terms of nodes) for generating 2mir_cuts cuts in branch-and-cut. [↔](#)

If $k > 0$, cuts are generated every k nodes, if $-99 < k < 0$ cuts are generated every $-k$ nodes but Cbc may decide to stop generating cuts, if not enough are generated at the root node, if $k=-99$ generate cuts only at the root node, if $k=0$ or 100 do not generate cuts.

Range: $[-100, \infty]$

Default: 0

acceptable_compl_inf_tol (*real*): 'Acceptance' threshold for the complementarity conditions. [↔](#)

Absolute tolerance on the complementarity. "Acceptable" termination requires that the max-norm of the (unscaled) complementarity is less than this threshold; see also acceptable_tol.

Default: 0.01

acceptable_constr_viol_tol (*real*): 'Acceptance' threshold for the constraint violation. [↔](#)

Absolute tolerance on the constraint violation. "Acceptable" termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold; see also acceptable_tol.

Default: 0.01

acceptable_dual_inf_tol (*real*): 'Acceptance' threshold for the dual infeasibility. [↔](#)

Absolute tolerance on the dual infeasibility. "Acceptable" termination requires that the (max-norm of the unscaled) dual infeasibility is less than this threshold; see also acceptable_tol.

Default: $1e+10$

acceptable_iter (*integer*): Number of 'acceptable' iterates before triggering termination. [↔](#)

If the algorithm encounters this many successive "acceptable" iterates (see "acceptable_tol"), it terminates, assuming that the problem has been solved to best possible accuracy given round-off. If it is set to zero, this heuristic is disabled.

Default: 15

acceptable_obj_change_tol (*real*): 'Acceptance' stopping criterion based on objective function change. [↔](#)

If the relative change of the objective function (scaled by $\text{Max}(1, |f(x)|)$) is less than this value, this part of the acceptable tolerance termination is satisfied; see also acceptable_tol. This is useful for the quasi-Newton option, which has trouble to bring down the dual infeasibility.

Default: $1e+20$

acceptable_tol (*real*): 'Acceptable' convergence tolerance (relative). [↔](#)

Determines which (scaled) overall optimality error is considered to be "acceptable." There are two levels of termination criteria. If the usual "desired" tolerances (see `tol`, `dual_inf_tol` etc) are satisfied at an iteration, the algorithm immediately terminates with a success message. On the other hand, if the algorithm encounters "acceptable_iter" many iterations in a row that are considered "acceptable", it will terminate before the desired convergence tolerance is met. This is useful in cases where the algorithm might not be able to achieve the "desired" level of accuracy.

Default: `1e-06`

accept_after_max_steps (*integer*): Accept a trial point after maximal this number of steps. [↔](#)

Even if it does not satisfy line search conditions.

Range: $[-1, \infty]$

Default: `-1`

accept_every_trial_step (*string*): Always accept the first trial step. [↔](#)

Setting this option to "yes" essentially disables the line search and makes the algorithm take aggressive steps, without global convergence guarantees.

Default: `no`

value	meaning
no	don't arbitrarily accept the full step
yes	always accept the full step

adaptive_mu_globalization (*string*): Globalization strategy for the adaptive mu selection mode. [↔](#)

To achieve global convergence of the adaptive version, the algorithm has to switch to the monotone mode (Fiacco-McCormick approach) when convergence does not seem to appear. This option sets the criterion used to decide when to do this switch. (Only used if option "mu_strategy" is chosen as "adaptive".)

Default: `obj-constr-filter`

value	meaning
kkt-error	nonmonotone decrease of kkt-error
never-monotone-mode	disables globalization
obj-constr-filter	2-dim filter for objective and constraint violation

adaptive_mu_kkterror_red_fact (*real*): Sufficient decrease factor for 'kkt-error' globalization strategy. [↔](#)

For the "kkt-error" based globalization strategy, the error must decrease by this factor to be deemed sufficient decrease.

Range: $[0, 1]$

Default: `0.9999`

adaptive_mu_kkterror_red_iters (*integer*): Maximum number of iterations requiring sufficient progress. [↔](#)

For the "kkt-error" based globalization strategy, sufficient progress must be made for "adaptive_mu_kkterror_red_iters" iterations. If this number of iterations is exceeded, the globalization strategy switches to the monotone mode.

Default: 4

adaptive_mu_kkt_norm_type (*string*): Norm used for the KKT error in the adaptive mu globalization strategies. [↔](#)

When computing the KKT error for the globalization strategies, the norm to be used is specified with this option. Note, this options is also used in the QualityFunctionMuOracle.

Default: 2-norm-squared

value	meaning
1-norm	use the 1-norm (abs sum)
2-norm	use 2-norm
2-norm-squared	use the 2-norm squared (sum of squares)
max-norm	use the infinity norm (max)

adaptive_mu_monotone_init_factor (*real*): Determines the initial value of the barrier parameter when switching to the monotone mode. [↔](#)

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode and fixed_mu_oracle is chosen as "average_compl", the barrier parameter is set to the current average complementarity times the value of "adaptive_mu_monotone_init_factor".

Default: 0.8

adaptive_mu_restore_previous_iterate (*string*): Indicates if the previous iterate should be restored if the monotone mode is entered. [↔](#)

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode, it can either start from the most recent iterate (no), or from the last iterate that was accepted (yes).

Default: no

value	meaning
no	don't restore accepted iterate
yes	restore accepted iterate

add_only_violated_oa (*string*): Do we add all OA cuts or only the ones violated by current point? [↔](#)

Default: no

value	meaning
no	Add all cuts
yes	Add only violated cuts

aggressive_fbbt (*string*): Aggressive feasibility-based bound tightening (to use with NLP points) [↔](#)

Aggressive FBBT is a version of probing that also allows to reduce the solution set, although it is not as quick as FBBT. It can be applied up to a certain depth of the B&B tree – see “log_num_abt_per_level”. In general, this option is useful but can be switched off if a problem is too large and seems not to benefit from it.

Default: **yes**

Values: **no, yes**

algorithm (*string*): Choice of the algorithm. [↔](#)

This will preset some of the options of bonmin depending on the algorithm choice.

Default: **B-BB**

value	meaning
b-bb	simple branch-and-bound algorithm,
b-ecp	ecp cuts based branch-and-cut a la FilMINT.
b-hyb	hybrid outer approximation based branch-and-cut,
b-ifp	Iterated Feasibility Pump for MINLP.
b-oa	OA Decomposition algorithm,
b-qg	Quesada and Grossmann branch-and-cut algorithm,

allowable_fraction_gap (*real*): Specify the value of relative gap under which the algorithm stops. [↔](#)

Stop the tree search when the gap between the objective value of the best known solution and the best bound on the objective of any solution is less than this fraction of the absolute value of the best known solution value.

Range: $[-\infty, \infty]$

Default: **0.1**

allowable_gap (*real*): Specify the value of absolute gap under which the algorithm stops. [↔](#)

Stop the tree search when the gap between the objective value of the best known solution and the best bound on the objective of any solution is less than this.

Range: $[-\infty, \infty]$

Default: **0**

alpha_for_y (*string*): Method to determine the step size for constraint multipliers. [↔](#)

This option determines how the step size (alpha_y) will be calculated when updating the constraint multipliers.

Default: **primal**

value	meaning
acceptor	Call LSacceptor to get step size for y
bound-mult	use step size for the bound multipliers (good for LPs)
dual-and-full	use the dual step size, and full step if $\delta_x \leq \text{alpha\_for\_y\_tol}$
full	take a full step of size one
max	use the max of primal and bound multipliers
min	use the min of primal and bound multipliers
min-dual-infeas	choose step size minimizing new dual infeasibility
primal	use primal step size
primal-and-full	use the primal step size, and full step if $\delta_x \leq \text{alpha\_for\_y\_tol}$

alpha_for_y_tol (*real*): Tolerance for switching to full equality multiplier steps. [↔](#)

This is only relevant if "alpha_for_y" is chosen "primal-and-full" or "dual-and-full". The step size for the equality constraint multipliers is taken to be one if the max-norm of the primal step is less than this tolerance.

Default: 10

alpha_min_frac (*real*): Safety factor for the minimal step size (before switching to restoration phase). [↔](#)

(This is gamma_alpha in Eqn. (20) in the implementation paper.)

Range: [0, 1]

Default: 0.05

alpha_red_factor (*real*): Fractional reduction of the trial step size in the backtracking line search. [↔](#)

At every step of the backtracking line search, the trial step size is reduced by this factor.

Range: [0, 1]

Default: 0.5

art_cutoff (*real*): Artificial cutoff [↔](#)

Default value is infinity.

Range: $[-\infty, \infty]$

Default: `maxdouble`

art_lower (*real*): Artificial lower bound [↔](#)

Default value is `-COIN_DBL_MAX`.

Range: $[-\infty, \infty]$

Default: `mindouble`

barrier_tol_factor (*real*): Factor for mu in barrier stop test. [↔](#)

The convergence tolerance for each barrier problem in the monotone mode is the value of the barrier parameter times "barrier_tol_factor". This option is also used in the adaptive mu strategy during the monotone mode. (This is kappa_epsilon in implementation paper).

Default: 10

bb_log_interval (*integer*): Interval at which node level output is printed. [↔](#)

Set the interval (in terms of number of nodes) at which a log on node resolutions (consisting of lower and upper bounds) is given.

Default: 100

bb_log_level (*integer*): specify main branch-and-bound log level. [↔](#)

Set the level of output of the branch-and-bound : 0 - none, 1 - minimal, 2 - normal low, 3 - normal high

Range: [0, 5]

Default: 1

boundtightening_print_level (*integer*): Output level for bound tightening code in Couenne [↔](#)

Range: [-2, 12]

Default: 0

bound_frac (*real*): Desired minimum relative distance from the initial point to bound. [↔](#)

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_push"). (This is kappa_2 in Section 3.6 of implementation paper.)

Range: [0, 0.5]

Default: 0.01

bound_mult_init_method (*string*): Initialization method for bound multipliers [↔](#)

This option defines how the iterates for the bound multipliers are initialized. If "constant" is chosen, then all bound multipliers are initialized to the value of "bound_mult_init_val". If "mu-based" is chosen, the each value is initialized to the the value of "mu_init" divided by the corresponding slack variable. This latter option might be useful if the starting point is close to the optimal solution.

Default: constant

value	meaning
constant	set all bound multipliers to the value of bound_mult_init_val
mu-based	initialize to mu_init/x_slack

bound_mult_init_val (*real*): Initial value for the bound multipliers. [↔](#)

All dual variables corresponding to bound constraints are initialized to this value.

Default: 1

bound_mult_reset_threshold (*real*): Threshold for resetting bound multipliers after the restoration phase. [↔](#)

After returning from the restoration phase, the bound multipliers are updated with a Newton step for complementarity. Here, the change in the primal variables during the entire restoration phase is taken to be the corresponding primal Newton step. However, if after the update the largest bound multiplier exceeds the threshold specified by this option, the multipliers are all reset to 1.

Default: 1000

bound_push (*real*): Desired minimum absolute distance from the initial point to bound. [↔](#)

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)

Default: 0.01

bound_relax_factor (*real*): Factor for initial relaxation of the bounds. [↔](#)

Before start of the optimization, the bounds given by the user are relaxed. This option sets the factor for this relaxation. If it is set to zero, then then bounds relaxation is disabled. (See Eqn.(35) in implementation paper.)

Default: 1e-10

branching_object (*string*): type of branching object for variable selection [↔](#)

Default: var_obj

value	meaning
expr_obj	use one object for each nonlinear expression
var_obj	use one object for each variable
vt_obj	use Violation Transfer from Tawarmalani and Sahinidis

branching_print_level (*integer*): Output level for braching code in Couenne [↔](#)

Range: [-2, 12]

Default: 0

branch_conv_cuts (*string*): Apply convexification cuts before branching (for now only within strong branching) [↔](#)

After applying a branching rule and before resolving the subproblem, generate a round of linearization cuts with the new bounds enforced by the rule.

Default: yes

Values: no, yes

branch_fbbt (*string*): Apply bound tightening before branching [↔](#)

After applying a branching rule and before re-solving the subproblem, apply Bound Tightening.

Default: yes

Values: no, yes

branch_lp_clamp (*real*): Defines safe interval percentage for using LP point as a branching point. [↔](#)

Range: [0, 1]

Default: 0.2

branch_lp_clamp_cube (*real*): Defines safe interval percentage [0,0.5] for using LP point as a branching point. [↔](#)

Range: $[0, 0.5]$

Default: 0.2

branch_lp_clamp_div (*real*): Defines safe interval percentage $[0,0.5]$ for using LP point as a branching point. [↩](#)

Range: $[0, 0.5]$

Default: 0.2

branch_lp_clamp_exp (*real*): Defines safe interval percentage $[0,0.5]$ for using LP point as a branching point. [↩](#)

Range: $[0, 0.5]$

Default: 0.2

branch_lp_clamp_log (*real*): Defines safe interval percentage $[0,0.5]$ for using LP point as a branching point. [↩](#)

Range: $[0, 0.5]$

Default: 0.2

branch_lp_clamp_negpow (*real*): Defines safe interval percentage $[0,0.5]$ for using LP point as a branching point. [↩](#)

Range: $[0, 0.5]$

Default: 0.2

branch_lp_clamp_pow (*real*): Defines safe interval percentage $[0,0.5]$ for using LP point as a branching point. [↩](#)

Range: $[0, 0.5]$

Default: 0.2

branch_lp_clamp_prod (*real*): Defines safe interval percentage $[0,0.5]$ for using LP point as a branching point. [↩](#)

Range: $[0, 0.5]$

Default: 0.2

branch_lp_clamp_sqr (*real*): Defines safe interval percentage $[0,0.5]$ for using LP point as a branching point. [↩](#)

Range: $[0, 0.5]$

Default: 0.2

branch_lp_clamp_trig (*real*): Defines safe interval percentage $[0,0.5]$ for using LP point as a branching point. [↩](#)

Range: $[0, 0.5]$

Default: 0.2

branch_midpoint_alpha (*real*): Defines convex combination of mid point and current LP point: $b = \alpha x_{lp} + (1-\alpha) (lb+ub)/2$. [↩](#)

Range: $[0, 1]$

Default: 0.25

branch_pt_select (*string*): Chooses branching point selection strategy [↩](#)

Default: mid-point

value	meaning
balanced	minimizes max distance from curve to convexification
lp-central	LP point if within $[k, 1-k]$ of the bound intervals, middle point otherwise (k defined by <code>branch.lp_clamp</code>)
lp-clamped	LP point clamped in $[k, 1-k]$ of the bound intervals (k defined by <code>lp_clamp</code>)
mid-point	convex combination of current point and mid point
min-area	minimizes total area of the two convexifications
no-branch	do not branch, return null infeasibility; for testing purposes only

branch_pt_select_cube (*string*): Chooses branching point selection strategy for operator cube. ↩

Default is to use the value of **branch_pt_select** (value `common`).

Default: `common`

Values: `balanced`, `common`, `lp-central`, `lp-clamped`, `mid-point`, `min-area`, `no-branch`

branch_pt_select_div (*string*): Chooses branching point selection strategy for operator div. ↩

Default is to use the value of **branch_pt_select** (value `common`).

Default: `common`

Values: `balanced`, `common`, `lp-central`, `lp-clamped`, `mid-point`, `min-area`, `no-branch`

branch_pt_select_exp (*string*): Chooses branching point selection strategy for operator exp. ↩

Default is to use the value of **branch_pt_select** (value `common`).

Default: `common`

Values: `balanced`, `common`, `lp-central`, `lp-clamped`, `mid-point`, `min-area`, `no-branch`

branch_pt_select_log (*string*): Chooses branching point selection strategy for operator log. ↩

Default is to use the value of **branch_pt_select** (value `common`).

Default: `common`

Values: `balanced`, `common`, `lp-central`, `lp-clamped`, `mid-point`, `min-area`, `no-branch`

branch_pt_select_negpow (*string*): Chooses branching point selection strategy for operator negpow. ↩

Default is to use the value of **branch_pt_select** (value `common`).

Default: `common`

Values: `balanced`, `common`, `lp-central`, `lp-clamped`, `mid-point`, `min-area`, `no-branch`

branch_pt_select_pow (*string*): Chooses branching point selection strategy for operator pow. ↩

Default is to use the value of **branch_pt_select** (value `common`).

Default: `common`

Values: `balanced`, `common`, `lp-central`, `lp-clamped`, `mid-point`, `min-area`, `no-branch`

branch_pt_select_prod (*string*): Chooses branching point selection strategy for operator prod. [↔](#)

Default is to use the value of **branch_pt_select** (value `common`).

Default: `common`

Values: `balanced`, `common`, `lp-central`, `lp-clamped`, `mid-point`, `min-area`, `no-branch`

branch_pt_select_sqr (*string*): Chooses branching point selection strategy for operator sqr. [↔](#)

Default is to use the value of **branch_pt_select** (value `common`).

Default: `common`

Values: `balanced`, `common`, `lp-central`, `lp-clamped`, `mid-point`, `min-area`, `no-branch`

branch_pt_select_trig (*string*): Chooses branching point selection strategy for operator trig. [↔](#)

Default is to use the value of **branch_pt_select** (value `common`).

Default: `common`

Values: `balanced`, `common`, `lp-central`, `lp-clamped`, `mid-point`, `min-area`, `no-branch`

candidate_sort_criterion (*string*): Choice of the criterion to choose candidates in strong-branching [↔](#)

Default: `best-ps-cost`

value	meaning
<code>best-ps-cost</code>	Sort by decreasing pseudo-cost
<code>least-fractional</code>	Sort by increasing integer infeasibility
<code>most-fractional</code>	Sort by decreasing integer infeasibility
<code>worst-ps-cost</code>	Sort by increasing pseudo-cost

check_derivatives_for_naninf (*string*): Indicates whether it is desired to check for Nan/Inf in derivative matrices [↔](#)

Activating this option will cause an error if an invalid number is detected in the constraint Jacobians or the Lagrangian Hessian. If this is not activated, the test is skipped, and the algorithm might proceed with invalid numbers and fail. If test is activated and an invalid number is detected, the matrix is written to output with `print_level` corresponding to `J_MORE_DETAILED`; so beware of large output!

Default: `no`

value	meaning
<code>no</code>	Don't check (faster).
<code>yes</code>	Check Jacobians and Hessian for Nan and Inf.

check_lp (*string*): Check all LPs through an independent call to `OsiClpSolverInterface::initialSolve()` [↔](#)

Default: `no`

Values: `no`, `yes`

clique_cuts (*integer*): Frequency k (in terms of nodes) for generating clique_cuts cuts in branch-and-cut. [↩](#)

See option **2mir_cuts** for the meaning of k .

Range: $[-100, \infty]$

Default: 0

clocktype (*string*): Type of clock to use for time_limit [↩](#)

Default: **wall**

value	meaning
cpu	CPU time
wall	Wall-clock time

coeff_var_threshold (*real*): Coefficient of variation threshold (for dynamic definition of cutoff_decr). [↩](#)

Default: 0.1

compl_inf_tol (*real*): Desired threshold for the complementarity conditions. [↩](#)

Absolute tolerance on the complementarity. Successful termination requires that the max-norm of the (unscaled) complementarity is less than this threshold.

Default: 0.0001

constraint_violation_norm_type (*string*): Norm to be used for the constraint violation in the line search. [↩](#)

Determines which norm should be used when the algorithm computes the constraint violation in the line search.

Default: **1-norm**

value	meaning
1-norm	use the 1-norm
2-norm	use the 2-norm
max-norm	use the infinity norm

constr_mult_init_max (*real*): Maximum allowed least-square guess of constraint multipliers. [↩](#)

Determines how large the initial least-square guesses of the constraint multipliers are allowed to be (in max-norm). If the guess is larger than this value, it is discarded and all constraint multipliers are set to zero. This options is also used when initializing the restoration phase. By default, "resto.constr_mult_init_max" (the one used in RestoIterateInitializer) is set to zero.

Default: 1000

constr_mult_reset_threshold (*real*): Threshold for resetting equality and inequality multipliers after restoration phase. [↩](#)

After returning from the restoration phase, the constraint multipliers are recomputed by a least square estimate. This option triggers when those least-square estimates should be ignored.

Default: 0

constr_viol_tol (*real*): Desired threshold for the constraint violation. [↔](#)

Absolute tolerance on the constraint violation. Successful termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold.

Default: 0.0001

cont_var_priority (*integer*): Priority of continuous variable branching [↔](#)

When branching, this is compared to the priority of integer variables, whose priority is given by `int_var_priority`, and SOS, whose priority is 10. Higher values mean smaller priority.

Range: $[1, \infty]$

Default: 99

convexification_cuts (*integer*): Specify the frequency (in terms of nodes) at which couenne ecg cuts are generated. [↔](#)

A frequency of 0 amounts to never solve the NLP relaxation.

Range: $[-99, \infty]$

Default: 1

convexification_points (*integer*): Specify the number of points at which to convexify when convexification type is uniform-grid or around-current-point. [↔](#)

Default: 4

convexification_type (*string*): Determines in which point the linear over/under-estimator are generated [↔](#)

For the lower envelopes of convex functions, this is the number of points where a supporting hyperplane is generated. This only holds for the initial linearization, as all other linearizations only add at most one cut per expression.

Default: `current-point-only`

value	meaning
<code>around-current-point</code>	At points around current optimum of relaxation
<code>current-point-only</code>	Only at current optimum of relaxation
<code>uniform-grid</code>	Points chosen in a uniform grid between the bounds of the problem

convexifying_print_level (*integer*): Output level for convexifying code in Couenne [↔](#)

Range: $[-2, 12]$

Default: 0

corrector_compl_avrg_red_fact (*real*): Complementarity tolerance factor for accepting corrector step. [↩](#)

This option determines the factor by which complementarity is allowed to increase for a corrector step to be accepted. Changing this option is experimental.

Default: 1

corrector_type (*string*): The type of corrector steps that should be taken. [↩](#)

If "mu_strategy" is "adaptive", this option determines what kind of corrector steps should be tried. Changing this option is experimental.

Default: none

value	meaning
affine	corrector step towards mu=0
none	no corrector
primal-dual	corrector step towards current mu

cover_cuts (*integer*): Frequency k (in terms of nodes) for generating cover_cuts cuts in branch-and-cut. [↩](#)

See option 2mir_cuts for the meaning of k.

Range: $[-100, \infty]$

Default: 0

crossconv_cuts (*integer*): The frequency (in terms of nodes) at which Couenne cross-aux convexification cuts are generated. [↩](#)

A frequency of 0 (default) means these cuts are never generated. Any positive number n instructs Couenne to generate them at every n nodes of the B&B tree. A negative number -n means that generation should be attempted at the root node, and if successful it can be repeated at every n nodes, otherwise it is stopped altogether.

Range: $[-99, \infty]$

Default: 0

cutoff (*real*): Specify cutoff value. [↩](#)

cutoff should be the value of a feasible solution known by the user (if any). The algorithm will only look for solutions better than cutoff.

Range: $[-1\text{e}+100, 1\text{e}+100]$

Default: 1e+100

cutoff_decr (*real*): Specify cutoff decrement. [↩](#)

Specify the amount by which cutoff is decremented below a new best upper-bound (usually a small positive value but in non-convex problems it may be a negative value).

Range: $[-1\text{e}+10, 1\text{e}+10]$

Default: 1e-05

delete_redundant (*string*): Eliminate redundant variables, which appear in the problem as x.k = x.h [↩](#)

Default: yes

value	meaning
no	Keep redundant variables, making the problem a bit larger
yes	Eliminate redundant variables (the problem will be equivalent, only smaller)

delta (*real*): Multiplier for constraint violation in the switching rule. [↔](#)

(See Eqn. (19) in the implementation paper.)

Default: 1

dependency_detection_with_rhs (*string*): Indicates if the right hand sides of the constraints should be considered during dependency detection [↔](#)

Default: no

value	meaning
no	only look at gradients
yes	also consider right hand side

dependency_detector (*string*): Indicates which linear solver should be used to detect linearly dependent equality constraints. [↔](#)

The default and available choices depend on how Ipopt has been compiled. This is experimental and does not work well.

Default: none

value	meaning
ma28	use MA28
mumps	use MUMPS
none	don't check; no extra work at beginning

disjcuts_print_level (*integer*): Output level for disjunctive cuts in Couenne [↔](#)

Range: [-2, 12]

Default: 0

disj_active_cols (*string*): Only include violated variable bounds in the Cut Generating LP (CGLP). [↔](#)

This reduces the size of the CGLP, but may produce less efficient cuts.

Default: no

Values: no, yes

disj_active_rows (*string*): Only include violated linear inequalities in the CGLP. [↔](#)

This reduces the size of the CGLP, but may produce less efficient cuts.

Default: no

Values: no, yes

disj_cumulative (*string*): Add previous disjunctive cut to current CGLP. [↔](#)

When generating disjunctive cuts on a set of disjunctions 1, 2, ..., k, introduce the cut relative to the previous disjunction i-1 in the CGLP used for disjunction i. Notice that, although this makes the cut generated more efficient, it increases the rank of the disjunctive cut generated.

Default: **no**

Values: **no, yes**

disj_depth_level (*integer*): Depth of the B&B tree when to start decreasing the number of objects that generate disjunctions. [↔](#)

This has a similar behavior as `log_num_obbt_per_level`. A value of -1 means that generation can be done at all nodes.

Range: $[-1, \infty]$

Default: 5

disj_depth_stop (*integer*): Depth of the B&B tree where separation of disjunctive cuts is stopped. [↔](#)

A value of -1 means that generation can be done at all nodes

Range: $[-1, \infty]$

Default: 20

disj_init_number (*integer*): Maximum number of disjunction to consider at each iteration. [↔](#)

-1 means no limit.

Range: $[-1, \infty]$

Default: 10

disj_init_perc (*real*): The maximum fraction of all disjunctions currently violated by the problem to consider for generating disjunctions. [↔](#)

Range: $[0, 1]$

Default: 0.5

diverging_iterates_tol (*real*): Threshold for maximal value of primal iterates. [↔](#)

If any component of the primal iterates exceeded this value (in absolute terms), the optimization is aborted with the exit message that the iterates seem to be diverging.

Default: **1e+20**

dual_inf_tol (*real*): Desired threshold for the dual infeasibility. [↔](#)

Absolute tolerance on the dual infeasibility. Successful termination requires that the max-norm of the (unscaled) dual infeasibility is less than this threshold.

Default: 1

dynamic_def_cutoff_decr (*string*): Do you want to define the parameter `cutoff_decr` dynamically? [↔](#)

Default: **no**

Values: **no**, **yes**

enable_dynamic_nlp (*string*): Enable dynamic linear and quadratic rows addition in nlp [↔](#)

Default: **no**

Values: **no**, **yes**

enable_lp_implied_bounds (*string*): Enable OsiSolverInterface::tightenBounds () – warning: it has caused some trouble to Couenne [↔](#)

Default: **no**

Values: **no**, **yes**

enable_sos (*string*): Use Special Ordered Sets (SOS) as indicated in the MINLP model [↔](#)

Default: **no**

Values: **no**, **yes**

estimate_select (*string*): How the min/max estimates of the subproblems' bounds are used in strong branching [↔](#)

Default: **normal**

value	meaning
normal	as usual in literature
product	use their product

eta_phi (*real*): Relaxation factor in the Armijo condition. [↔](#)

(See Eqn. (20) in the implementation paper)

Range: [0, 0.5]

Default: **1e-08**

evaluate_orig_obj_at_resto_trial (*string*): Determines if the original objective function should be evaluated at restoration phase trial points. [↔](#)

Setting this option to "yes" makes the restoration phase algorithm evaluate the objective function of the original problem at every trial point encountered during the restoration phase, even if this value is not required. In this way, it is guaranteed that the original objective function can be evaluated without error at all accepted iterates; otherwise the algorithm might fail at a point where the restoration phase accepts an iterate that is good for the restoration phase problem, but not the original problem. On the other hand, if the evaluation of the original objective is expensive, this might be costly.

Default: **yes**

value	meaning
no	skip evaluation
yes	evaluate at every trial point

expect_infeasible_problem (*string*): Enable heuristics to quickly detect an infeasible problem. [↔](#)

This options is meant to activate heuristics that may speed up the infeasibility determination if you expect that there is a good chance for the problem to be infeasible. In the filter line search procedure, the restoration phase is called more quickly than usually, and more reduction in the constraint violation is enforced before the restoration phase is left. If the problem is square, this option is enabled automatically.

Default: **no**

value	meaning
no	the problem probably be feasible
yes	the problem has a good chance to be infeasible

expect_infeasible_problem_ctol (*real*): Threshold for disabling 'expect_infeasible_problem' option. [↔](#)

If the constraint violation becomes smaller than this threshold, the "expect_infeasible_problem" heuristics in the filter line search are disabled. If the problem is square, this options is set to 0.

Default: 0.001

expect_infeasible_problem_ytol (*real*): Multiplier threshold for activating 'expect_infeasible_problem' option. [↔](#)

If the max norm of the constraint multipliers becomes larger than this value and "expect_infeasible_problem" is chosen, then the restoration phase is entered.

Default: 1e+08

fast_step_computation (*string*): Indicates if the linear system should be solved quickly. [↔](#)

If set to yes, the algorithm assumes that the linear system that is solved to obtain the search direction, is solved sufficiently well. In that case, no residuals are computed, and the computation of the search direction is a little faster.

Default: **no**

value	meaning
no	Verify solution of linear system by computing residuals.
yes	Trust that linear systems are solved well.

feasibility_bt (*string*): Feasibility-based (cheap) bound tightening (FBBT) [↔](#)

A pre-processing technique to reduce the bounding box, before the generation of linearization cuts. This is a quick and effective way to reduce the solution set, and it is highly recommended to keep it active.

Default: **yes**

Values: **no**, **yes**

feasibility_pump_objective_norm (*integer*): Norm of feasibility pump objective function [↔](#)

Range: [1, 2]

Default: 1

feas_pump_convcuts (*string*): Separate MILP-feasible, MINLP-infeasible solution during or after MILP solver. ↩

Default: none

value	meaning
external	Done after the MILP solver, in a Benders-like fashion
integrated	Done within the MILP solver in a branch-and-cut fashion
none	Just proceed to the NLP
postcut	Do one round of cuts and proceed with NLP

feas_pump_fademult (*real*): decrease/increase rate of multipliers ↩

1 keeps initial multipliers from one call to the next; any <1 multiplies ALL of them

Range: [0, 1]

Default: 1

feas_pump_heuristic (*string*): Apply the nonconvex Feasibility Pump ↩

An implementation of the Feasibility Pump for nonconvex MINLPs

Default: no

value	meaning
no	never called
once	call it at most once
only	Call it exactly once and then exit
yes	called any time Cbc calls heuristics

feas_pump_iter (*integer*): Number of iterations in the main Feasibility Pump loop ↩

-1 means no limit

Range: [-1, ∞]

Default: 10

feas_pump_level (*integer*): Specify the logarithm of the number of feasibility pumps to perform on average for each level of given depth of the tree. ↩

Solve as many nlp's at the nodes for each level of the tree. Nodes are randomly selected. If for a given level there are less nodes than this number nlp are solved for every nodes. For example, if parameter is 8 NLPs are solved for all node until level 8, then for half the node at level 9, 1/4 at level 10.... Set to -1 to perform at all nodes.

Range: [-1, ∞]

Default: 3

feas_pump_milpmethod (*integer*): How should the integral solution be constructed? ↩

0: automatic, 1: aggressive heuristics, large node limit, 2: default, node limit, 3: RENS, 4: Objective Feasibility Pump, 5: MINLP rounding heuristic, 6: rounding, -1: solve MILP completely

Range: $[-1, 6]$

Default: 0

feas_pump_mult_dist_milp (*real*): Weight of the distance in the distance function of the milp problem
↔

0: neglected; 1: full weight; a in $]0,1[$: weight is a^k where k is the FP iteration; a in $]-1,0[$: weight is $1 - |a|^k$

Range: $[-1, 1]$

Default: 0

feas_pump_mult_dist_nlp (*real*): Weight of the distance in the distance function of the nlp problem ↔

0: neglected; 1: full weight; a in $]0,1[$: weight is a^k where k is the FP iteration; a in $]-1,0[$: weight is $1 - |a|^k$

Range: $[-1, 1]$

Default: 0

feas_pump_mult_hess_milp (*real*): Weight of the Hessian in the distance function of the milp problem
↔

0: neglected; 1: full weight; a in $]0,1[$: weight is a^k where k is the FP iteration; a in $]-1,0[$: weight is $1 - |a|^k$

Range: $[-1, 1]$

Default: 0

feas_pump_mult_hess_nlp (*real*): Weight of the Hessian in the distance function of the nlp problem ↔

0: neglected; 1: full weight; a in $]0,1[$: weight is a^k where k is the FP iteration; a in $]-1,0[$: weight is $1 - |a|^k$

Range: $[-1, 1]$

Default: 0

feas_pump_mult_objf_milp (*real*): Weight of the original objective function in the distance function of the milp problem ↔

0: neglected; 1: full weight; a in $]0,1[$: weight is a^k where k is the FP iteration; a in $]-1,0[$: weight is $1 - |a|^k$

Range: $[-1, 1]$

Default: 0

feas_pump_mult_objf_nlp (*real*): Weight of the original objective function in the distance function of the nlp problem ↔

0: neglected; 1: full weight; a in $]0,1[$: weight is a^k where k is the FP iteration; a in $] -1,0[$: weight is $1 - |a|^k$

Range: $[-1, 1]$

Default: 0

feas_pump_nsegrounds (*integer*): Number of rounds of convexification cuts. [↔](#)

Range: $[1, 100000]$

Default: 4

feas_pump_poolcomp (*integer*): Priority field to compare solutions in FP pool [↔](#)

0: total number of infeasible objects (integer and nonlinear); 1: maximum infeasibility (integer or nonlinear); 2: objective value; 3: compare value of all variables; 4: compare value of all integers (RECOMMENDED).

Range: $[0, 4]$

Default: 4

feas_pump_tabumgt (*string*): Retrieval of MILP solutions when the one returned is unsatisfactory [↔](#)

Default: pool

value	meaning
cut	Separate convexification cuts
none	Bail out of feasibility pump
perturb	Randomly perturb unsatisfactory solution
pool	Use a solution pool and replace unsatisfactory solution with Euclidean-closest in pool

feas_pump_usescip (*string*): Should SCIP be used to solve the MILPs? [↔](#)

Note, that SCIP is only available for GAMS users with a SCIP or an academic GAMS license.

Default: yes

value	meaning
no	Use Cbc's branch-and-cut to solve the MILP
yes	Use SCIP's branch-and-cut or heuristics (see <code>feas_pump_milpmethod</code> option) to solve the MILP

feas_pump_vardist (*string*): Distance computed on integer-only or on both types of variables, in different flavors. [↔](#)

Default: integer

value	meaning
all	Compute the distance using continuous and integer variables
int-postprocess	Use a post-processing fixed-IP LP to determine a closest-point solution

value	meaning
integer	Only compute the distance based on integer coordinates (use post-processing if numerical errors occur)

feas_tolerance (*real*): Tolerance for constraints/auxiliary variables ↔

Default value is 1e-5.

Range: $[-\infty, \infty]$

Default: 1e-05

filter_margin_fact (*real*): Factor determining width of margin for obj-constr-filter adaptive globalization strategy. ↔

When using the adaptive globalization strategy, "obj-constr-filter", sufficient progress for a filter entry is defined as follows: (new obj) < (filter obj) - filter_margin_fact*(new constr-viol) OR (new constr-viol) < (filter constr-viol) - filter_margin_fact*(new constr-viol). For the description of the "kkt-error-filter" option see "filter_max_margin".

Range: $[0, 1]$

Default: 1e-05

filter_max_margin (*real*): Maximum width of margin in obj-constr-filter adaptive globalization strategy. ↔

Default: 1

filter_reset_trigger (*integer*): Number of iterations that trigger the filter reset. ↔

If the filter reset heuristic is active and the number of successive iterations in which the last rejected trial step size was rejected because of the filter, the filter is reset.

Range: $[1, \infty]$

Default: 5

first_hessian_perturbation (*real*): Size of first x-s perturbation tried. ↔

The first value tried for the x-s perturbation in the inertia correction scheme.(This is delta_0 in the implementation paper.)

Default: 0.0001

first_perc_for_cutoff_decr (*real*): The percentage used when, the coeff of variance is smaller than the threshold, to compute the cutoff_decr dynamically. ↔

Range: $[-\infty, \infty]$

Default: -0.02

fixed_mu_oracle (*string*): Oracle for the barrier parameter when switching to fixed mode. ↔

Determines how the first value of the barrier parameter should be computed when switching to the "monotone mode" in the adaptive strategy. (Only considered if "adaptive" is selected for option "mu_strategy".)

Default: average_comp1

value	meaning
average_compl	base on current average complementarity
loqo	LOQO's centrality rule
probing	Mehrotra's probing heuristic
quality-function	minimize a quality function

fixed_variable_treatment (*string*): Determines how fixed variables should be handled. [↔](#)

The main difference between those options is that the starting point in the "make_constraint" case still has the fixed variables at their given values, whereas in the case "make_parameter" the functions are always evaluated with the fixed values for those variables. Also, for "relax_bounds", the fixing bound constraints are relaxed (according to "bound_relax_factor"). For both "make_constraints" and "relax_bounds", bound multipliers are computed for the fixed variables.

Default: `make_parameter`

value	meaning
make_constraint	Add equality constraints fixing variables
make_parameter	Remove fixed variable from optimization variables
relax_bounds	Relax fixing bound constraints

fixpoint_bt (*integer*): The frequency (in terms of nodes) at which Fix Point Bound Tightening is performed. [↔](#)

A frequency of 0 (default) means these cuts are never generated. Any positive number n instructs Couenne to generate them at every n nodes of the B&B tree. A negative number $-n$ means that generation should be attempted at the root node, and if successful it can be repeated at every n nodes, otherwise it is stopped altogether.

Range: $[-99, \infty]$

Default: 0

fixpoint_bt_model (*string*): Choose whether to add an extended fixpoint LP model or a more compact one. [↔](#)

The "extended" option is for debugging purposes; the compact formulation is equivalent and this option should be used

Default: `compact`

value	meaning
compact	Compact equivalent model obtained by projecting lower/upper bounds of rhs
extended	Extended model with variables for lower/upper bounds of right-hand sides (see paper by Belotti, Cafieri, Lee, Liberti)

flow_covers_cuts (*integer*): Frequency k (in terms of nodes) for generating flow_covers_cuts cuts in branch-and-cut. [↔](#)

See option `2mir_cuts` for the meaning of k .

Range: $[-100, \infty]$

Default: 0

gamma_phi (*real*): Relaxation factor in the filter margin for the barrier function. [↔](#)

(See Eqn. (18a) in the implementation paper.)

Range: [0, 1]

Default: 1e-08

gamma_theta (*real*): Relaxation factor in the filter margin for the constraint violation. [↔](#)

(See Eqn. (18b) in the implementation paper.)

Range: [0, 1]

Default: 1e-05

Gomory_cuts (*integer*): Frequency k (in terms of nodes) for generating Gomory_cuts cuts in branch-and-cut. [↔](#)

See option **2mir_cuts** for the meaning of k.

Range: [-100, ∞]

Default: 0

hessian_approximation (*string*): Indicates what Hessian information is to be used. [↔](#)

This determines which kind of information for the Hessian of the Lagrangian function is used by the algorithm.

Default: **exact**

value	meaning
exact	Use second derivatives provided by the NLP.
limited-memory	Perform a limited-memory quasi-Newton approximation

hessian_approximation_space (*string*): Indicates in which subspace the Hessian information is to be approximated. [↔](#)

Default: **nonlinear-variables**

value	meaning
all-variables	in space of all variables (without slacks)
nonlinear-variables	only in space of nonlinear variables.

heuristic_dive_fractional (*string*): if yes runs the Dive Fractional heuristic [↔](#)

Default: **no**

Values: **no**, **yes**

heuristic_dive_MIP_fractional (*string*): if yes runs the Dive MIP Fractional heuristic [↔](#)

Default: **no**

Values: **no**, **yes**

heuristic_dive_MIP_vectorLength (*string*): if yes runs the Dive MIP VectorLength heuristic [↔](#)

Default: **no**

Values: **no**, **yes**

heuristic_dive_vectorLength (*string*): if yes runs the Dive VectorLength heuristic [↔](#)

Default: **no**

Values: **no**, **yes**

heuristic_feasibility_pump (*string*): whether the heuristic feasibility pump should be used [↔](#)

Default: **no**

Values: **no**, **yes**

heuristic_RINS (*string*): if yes runs the RINS heuristic [↔](#)

Default: **no**

Values: **no**, **yes**

honor_original_bounds (*string*): Indicates whether final points should be projected into original bounds. [↔](#)

Ipopt might relax the bounds during the optimization (see, e.g., option "bound_relax_factor"). This option determines whether the final point should be projected back into the user-provide original bounds after the optimization.

Default: **yes**

value	meaning
no	Leave final point unchanged
yes	Project final point back into original bounds

inf_pr_output (*string*): Determines what value is printed in the 'inf_pr' output column. [↔](#)

Ipopt works with a reformulation of the original problem, where slacks are introduced and the problem might have been scaled. The choice "internal" prints out the constraint violation of this formulation. With "original" the true constraint violation in the original NLP is printed.

Default: **original**

value	meaning
internal	max-norm of violation of internal equality constraints
original	maximal constraint violation in original NLP

integer_tolerance (*real*): Set integer tolerance. [↔](#)

Any number within that value of an integer is considered integer.

Default: `1e-06`

int_var_priority (*integer*): Priority of integer variable branching ↩

When branching, this is compared to the priority of continuous variables, whose priority is given by `cont_var_priority`, and SOS, whose priority is 10. Higher values mean smaller priority.

Range: $[1, \infty]$

Default: `98`

iteration_limit (*integer*): Set the cumulative maximum number of iteration in the algorithm used to process nodes continuous relaxations in the branch-and-bound. ↩

value 0 deactivates option.

Default: `maxint`

iterative_rounding_aggressiveness (*integer*): Aggressiveness of the Iterative Rounding heuristic ↩

Set the aggressiveness of the heuristic; i.e., how many iterations should be run, and with which parameters. The maximum time can be overridden by setting the `_time` and `_time_firstcall` options. 0 = non aggressive, 1 = standard (default), 2 = aggressive.

Range: $[0, 2]$

Default: `1`

iterative_rounding_base_lbrhs (*integer*): Base rhs of the local branching constraint for Iterative Rounding ↩

Base rhs for the local branching constraint that defines a neighbourhood of the local incumbent. The base rhs is modified by the algorithm according to variable bounds. This corresponds to k' in the paper. Default 15.

Default: `15`

iterative_rounding_heuristic (*string*): Do we use the Iterative Rounding heuristic ↩

If enabled, a heuristic based on Iterative Rounding is used to find feasible solutions for the problem. The heuristic may take some time, but usually finds good solutions. Recommended if you want good upper bounds and have Cplex. Not recommended if you do not have Cplex

Default: `no`

Values: `no`, `yes`

iterative_rounding_num_fir_points (*integer*): Max number of points rounded at the beginning of Iterative Rounding ↩

Number of different points (obtained solving a log-barrier problem) that the heuristic will try to round at most, during its execution at the root node (i.e. the F-IR heuristic). Default 5.

Range: $[1, \infty]$

Default: `5`

iterative_rounding_omega (*real*): Omega parameter of the Iterative Rounding heuristic [↔](#)

Set the omega parameter of the heuristic, which represents a multiplicative factor for the minimum log-barrier parameter of the NLP which is solved to obtain feasible points. This corresponds to ω' in the paper. Default 0.2.

Range: $[0, 1]$

Default: 0.2

iterative_rounding_time (*real*): Specify the maximum time allowed for the Iterative Rounding heuristic [↔](#)

Maximum CPU time employed by the Iterative Rounding heuristic; if no solution found in this time, failure is reported. This overrides the CPU time set by Aggressiveness if positive.

Range: $[-\infty, \infty]$

Default: -1

iterative_rounding_time_firstcall (*real*): Specify the maximum time allowed for the Iterative Rounding heuristic when no feasible solution is known [↔](#)

Maximum CPU time employed by the Iterative Rounding heuristic when no solution is known; if no solution found in this time, failure is reported. This overrides the CPU time set by Aggressiveness if positive.

Range: $[-\infty, \infty]$

Default: -1

jacobian_regularization_exponent (*real*): Exponent for mu in the regularization for rank-deficient constraint Jacobians. [↔](#)

(This is kappa_c in the implementation paper.)

Default: 0.25

jacobian_regularization_value (*real*): Size of the regularization for rank-deficient constraint Jacobians. [↔](#)

(This is bar delta_c in the implementation paper.)

Default: 1e-08

jac_c_constant (*string*): Indicates whether all equality constraints are linear [↔](#)

Activating this option will cause Ipopt to ask for the Jacobian of the equality constraints only once from the NLP and reuse this information later.

Default: no

value	meaning
no	Don't assume that all equality constraints are linear
yes	Assume that equality constraints Jacobian are constant

jac_d_constant (*string*): Indicates whether all inequality constraints are linear [↔](#)

Activating this option will cause Ipopt to ask for the Jacobian of the inequality constraints only once from the NLP and reuse this information later.

Default: no

value	meaning
no	Don't assume that all inequality constraints are linear
yes	Assume that equality constraints Jacobian are constant

kappa_d (*real*): Weight for linear damping term (to handle one-sided bounds). [↔](#)

(see Section 3.7 in implementation paper.)

Default: 1e-05

kappa_sigma (*real*): Factor limiting the deviation of dual variables from primal estimates. [↔](#)

If the dual variables deviate from their primal estimates, a correction is performed. (See Eqn. (16) in the implementation paper.) Setting the value to less than 1 disables the correction.

Default: 1e+10

kappa_soc (*real*): Factor in the sufficient reduction rule for second order correction. [↔](#)

This option determines how much a second order correction step must reduce the constraint violation so that further correction steps are attempted. (See Step A-5.9 of Algorithm A in the implementation paper.)

Default: 0.99

least_square_init_duals (*string*): Least square initialization of all dual variables [↔](#)

If set to yes, Ipopt tries to compute least-square multipliers (considering ALL dual variables). If successful, the bound multipliers are possibly corrected to be at least bound_mult_init_val. This might be useful if the user doesn't know anything about the starting point, or for solving an LP or QP. This overwrites option "bound_mult_init_method".

Default: no

value	meaning
no	use bound_mult_init_val and least-square equality constraint multipliers
yes	overwrite user-provided point with least-square estimates

least_square_init_primal (*string*): Least square initialization of the primal variables [↔](#)

If set to yes, Ipopt ignores the user provided point and solves a least square problem for the primal variables (x and s), to fit the linearized equality and inequality constraints. This might be useful if the user doesn't know anything about the starting point, or for solving an LP or QP.

Default: no

value	meaning
no	take user-provided point
yes	overwrite user-provided point with least-square estimates

lift_and_project_cuts (*integer*): Frequency k (in terms of nodes) for generating lift_and_project_cuts cuts in branch-and-cut. ↩

See option `2mir_cuts` for the meaning of k .

Range: $[-100, \infty]$

Default: 0

limited_memory_aug_solver (*string*): Strategy for solving the augmented system for low-rank Hessian. ↩

Default: `sherman-morrison`

value	meaning
extended	use an extended augmented system
sherman-morrison	use Sherman-Morrison formula

limited_memory_initialization (*string*): Initialization strategy for the limited memory quasi-Newton approximation. ↩

Determines how the diagonal Matrix B_0 as the first term in the limited memory approximation should be computed.

Default: `scalar1`

value	meaning
constant	$\sigma = \text{limited\_memory\_init\_val}$
scalar1	$\sigma = s^T y / s^T s$
scalar2	$\sigma = y^T y / s^T y$
scalar3	arithmetic average of scalar1 and scalar2
scalar4	geometric average of scalar1 and scalar2

limited_memory_init_val (*real*): Value for B_0 in low-rank update. ↩

The starting matrix in the low rank update, B_0 , is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Default: 1

limited_memory_init_val_max (*real*): Upper bound on value for B_0 in low-rank update. ↩

The starting matrix in the low rank update, B_0 , is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Default: `1e+08`

limited_memory_init_val_min (*real*): Lower bound on value for B0 in low-rank update. [↩](#)

The starting matrix in the low rank update, B0, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Default: 1e-08

limited_memory_max_history (*integer*): Maximum size of the history for the limited quasi-Newton Hessian approximation. [↩](#)

This option determines the number of most recent iterations that are taken into account for the limited-memory quasi-Newton approximation.

Default: 6

limited_memory_max_skipping (*integer*): Threshold for successive iterations where update is skipped. [↩](#)

If the update is skipped more than this number of successive iterations, we quasi-Newton approximation is reset.

Range: $[1, \infty]$

Default: 2

limited_memory_special_for_resto (*string*): Determines if the quasi-Newton updates should be special during the restoration phase. [↩](#)

Until Nov 2010, Ipopt used a special update during the restoration phase, but it turned out that this does not work well. The new default uses the regular update procedure and it improves results. If for some reason you want to get back to the original update, set this option to "yes".

Default: no

value	meaning
no	use the same update as in regular iterations
yes	use the a special update during restoration phase

limited_memory_update_type (*string*): Quasi-Newton update formula for the limited memory approximation. [↩](#)

Determines which update formula is to be used for the limited-memory quasi-Newton approximation.

Default: bfgs

value	meaning
bfgs	BFGS update (with skipping)
sr1	SR1 (not working well)

linear_scaling_on_demand (*string*): Flag indicating that linear scaling is only done if it seems required. [↩](#)

This option is only important if a linear scaling method (e.g., mc19) is used. If you choose "no", then the scaling factors are computed for every linear system from the start. This can be quite expensive. Choosing "yes" means that the algorithm will start the scaling method only when the solutions to the linear system seem not good, and then use it until the end.

Default: **yes**

value	meaning
no	Always scale the linear system.
yes	Start using linear system scaling if solutions seem not good.

linear_solver (*string*): Linear solver used for step computations. [↔](#)

Determines which linear algebra package is to be used for the solution of the augmented linear system (for obtaining the search directions). Note, the code must have been compiled with the linear solver you want to choose. Depending on your Ipopt installation, not all options are available.

Default: **ma27**

value	meaning
ma27	use the Harwell routine MA27
ma57	use the Harwell routine MA57
ma77	use the Harwell routine HSL_MA77
ma86	use the Harwell routine HSL_MA86
ma97	use the Harwell routine HSL_MA97
mumps	use MUMPS package
pardiso	use the Pardiso package

linear_system_scaling (*string*): Method for scaling the linear system. [↔](#)

Determines the method used to compute symmetric scaling factors for the augmented system (see also the "linear_scaling_on_demand" option). This scaling is independent of the NLP problem scaling. By default, MC19 is only used if MA27 or MA57 are selected as linear solvers. This value is only available if Ipopt has been compiled with MC19.

Default: **mc19**

value	meaning
mc19	use the Harwell routine MC19
none	no scaling will be performed
slack-based	use the slack values

line_search_method (*string*): Globalization method used in backtracking line search [↔](#)

Only the "filter" choice is officially supported. But sometimes, good results might be obtained with the other choices.

Default: **filter**

value	meaning
cg-penalty	Chen-Goldfarb penalty function

value	meaning
filter	Filter method
penalty	Standard penalty function

local_branching_heuristic (*string*): Apply local branching heuristic ↩

A local-branching heuristic based is used to find feasible solutions.

Default: **no**

Values: **no**, **yes**

local_optimization_heuristic (*string*): Search for local solutions of MINLPs ↩

If enabled, a heuristic based on Ipopt is used to find feasible solutions for the problem. It is highly recommended that this option is left enabled, as it would be difficult to find feasible solutions otherwise.

Default: **yes**

Values: **no**, **yes**

log_num_abt_per_level (*integer*): Specify the frequency (in terms of nodes) for aggressive bound tightening. ↩

If -1, apply at every node (expensive!). If 0, apply at root node only. If $k \geq 0$, apply with probability $2^{-(k - \text{level})}$, level being the current depth of the B&B tree.

Range: $[-1, \infty]$

Default: 2

log_num_local_optimization_per_level (*integer*): Specify the logarithm of the number of local optimizations to perform on average for each level of given depth of the tree. ↩

Solve as many nlp's at the nodes for each level of the tree. Nodes are randomly selected. If for a given level there are less nodes than this number nlp are solved for every nodes. For example if parameter is 8, nlp's are solved for all node until level 8, then for half the node at level 9, 1/4 at level 10.... Value -1 specify to perform at all nodes.

Range: $[-1, \infty]$

Default: 2

log_num_obbt_per_level (*integer*): Specify the frequency (in terms of nodes) for optimality-based bound tightening. ↩

If -1, apply at every node (expensive!). If 0, apply at root node only. If $k \geq 0$, apply with probability $2^{-(k - \text{level})}$, level being the current depth of the B&B tree.

Range: $[-1, \infty]$

Default: 1

lp_log_level (*integer*): specify LP log level. ↩

Set the level of output of the linear programming sub-solver in B-Hyb or B-QG : 0 - none, 1 - minimal, 2 - normal low, 3 - normal high, 4 - verbose

Range: $[0, 4]$

Default: 0

ma27_ignore_singularity (*string*): Enables MA27's ability to solve a linear system even if the matrix is singular. ↩

Setting this option to "yes" means that Ipopt will call MA27 to compute solutions for right hand sides, even if MA27 has detected that the matrix is singular (but is still able to solve the linear system). In some cases this might be better than using Ipopt's heuristic of small perturbation of the lower diagonal of the KKT matrix.

Default: **no**

value	meaning
no	Don't have MA27 solve singular systems
yes	Have MA27 solve singular systems

ma27_la_init_factor (*real*): Real workspace memory for MA27. [↔](#)

The initial real workspace memory = la_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by meminc_factor if required. This option is only available if Ipopt has been compiled with MA27.

Range: $[1, \infty]$

Default: 5

ma27_liw_init_factor (*real*): Integer workspace memory for MA27. [↔](#)

The initial integer workspace memory = liw_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by meminc_factor if required. This option is only available if Ipopt has been compiled with MA27.

Range: $[1, \infty]$

Default: 5

ma27_meminc_factor (*real*): Increment factor for workspace size for MA27. [↔](#)

If the integer or real workspace is not large enough, Ipopt will increase its size by this factor. This option is only available if Ipopt has been compiled with MA27.

Range: $[1, \infty]$

Default: 2

ma27_pivtol (*real*): Pivot tolerance for the linear solver MA27. [↔](#)

A smaller number pivots for sparsity, a larger number pivots for stability. This option is only available if Ipopt has been compiled with MA27.

Range: $[0, 1]$

Default: 1e-08

ma27_pivtolmax (*real*): Maximum pivot tolerance for the linear solver MA27. [↔](#)

Ipopt may increase pivtol as high as pivtolmax to get a more accurate solution to the linear system. This option is only available if Ipopt has been compiled with MA27.

Range: $[0, 1]$

Default: 0.0001

ma27_skip_inertia_check (*string*): Always pretend inertia is correct. [↔](#)

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Default: no

value	meaning
no	check inertia
yes	skip inertia check

ma28_pivtol (*real*): Pivot tolerance for linear solver MA28. [↔](#)

This is used when MA28 tries to find the dependent constraints.

Range: [0, 1]

Default: 0.01

ma57_automatic_scaling (*string*): Controls MA57 automatic scaling [↔](#)

This option controls the internal scaling option of MA57. For higher reliability of the MA57 solver, you may want to set this option to yes. This is ICNTL(15) in MA57.

Default: no

value	meaning
no	Do not scale the linear system matrix
yes	Scale the linear system matrix

ma57_block_size (*integer*): Controls block size used by Level 3 BLAS in MA57BD [↔](#)

This is ICNTL(11) in MA57.

Range: [1, ∞]

Default: 16

ma57_node_amalgamation (*integer*): Node amalgamation parameter [↔](#)

This is ICNTL(12) in MA57.

Range: [1, ∞]

Default: 16

ma57_pivot_order (*integer*): Controls pivot order in MA57 [↔](#)

This is ICNTL(6) in MA57.

Range: [0, 5]

Default: 5

ma57_pivtol (*real*): Pivot tolerance for the linear solver MA57. [↔](#)

A smaller number pivots for sparsity, a larger number pivots for stability. This option is only available if Ipopt has been compiled with MA57.

Range: [0, 1]

Default: 1e-08

ma57_pivtolmax (*real*): Maximum pivot tolerance for the linear solver MA57. [↔](#)

Ipopt may increase pivtol as high as ma57_pivtolmax to get a more accurate solution to the linear system. This option is only available if Ipopt has been compiled with MA57.

Range: $[0, 1]$

Default: 0.0001

ma57_pre_alloc (*real*): Safety factor for work space memory allocation for the linear solver MA57. [↔](#)

If 1 is chosen, the suggested amount of work space is used. However, choosing a larger number might avoid reallocation if the suggest values do not suffice. This option is only available if Ipopt has been compiled with MA57.

Range: $[1, \infty]$

Default: 1.05

ma57_small_pivot_flag (*integer*): If set to 1, then when small entries defined by CNTL(2) are detected they are removed and the corresponding pivots placed at the end of the factorization. This can be particularly efficient if the matrix is highly rank deficient. [↔](#)

This is ICNTL(16) in MA57.

Range: $[0, 1]$

Default: 0

ma77_buffer_lpage (*integer*): Number of scalars per MA77 buffer page [↔](#)

Number of scalars per an in-core buffer in the out-of-core solver MA77. Must be at most ma77_file_size.

Range: $[1, \infty]$

Default: 4096

ma77_buffer_npage (*integer*): Number of pages that make up MA77 buffer [↔](#)

Number of pages of size buffer_lpage that exist in-core for the out-of-core solver MA77.

Range: $[1, \infty]$

Default: 1600

ma77_file_size (*integer*): Target size of each temporary file for MA77, scalars per type [↔](#)

MA77 uses many temporary files, this option controls the size of each one. It is measured in the number of entries (int or double), NOT bytes.

Range: $[1, \infty]$

Default: 2097152

ma77_maxstore (*integer*): Maximum storage size for MA77 in-core mode [↔](#)

If greater than zero, the maximum size of factors stored in core before out-of-core mode is invoked.

Default: 0

ma77_nemin (*integer*): Node Amalgamation parameter [↔](#)

Two nodes in elimination tree are merged if result has fewer than ma77_nemin variables.

Range: $[1, \infty]$

Default: 8

ma77_order (*string*): Controls type of ordering used by HSL_MA77 [↔](#)

This option controls ordering for the solver HSL_MA77.

Default: `metis`

value	meaning
amd	Use the HSL_MC68 approximate minimum degree algorithm
metis	Use the MeTiS nested dissection algorithm (if available)

ma77_print_level (*integer*): Debug printing level for the linear solver MA77 ↩

Range: $[-\infty, \infty]$

Default: -1

ma77_small (*real*): Zero Pivot Threshold ↩

Any pivot less than `ma77_small` is treated as zero.

Default: 1e-20

ma77_static (*real*): Static Pivoting Threshold ↩

See MA77 documentation. Either `ma77_static=0.0` or `ma77_static>ma77_small`.
`ma77_static=0.0` disables static pivoting.

Default: 0

ma77_u (*real*): Pivoting Threshold ↩

See MA77 documentation.

Range: $[0, 0.5]$

Default: 1e-08

ma77_umax (*real*): Maximum Pivoting Threshold ↩

Maximum value to which `u` will be increased to improve quality.

Range: $[0, 0.5]$

Default: 0.0001

ma86_nemin (*integer*): Node Amalgamation parameter ↩

Two nodes in elimination tree are merged if result has fewer than `ma86_nemin` variables.

Range: $[1, \infty]$

Default: 32

ma86_order (*string*): Controls type of ordering used by HSL_MA86 ↩

This option controls ordering for the solver HSL_MA86.

Default: `auto`

value	meaning
amd	Use the HSL_MC68 approximate minimum degree algorithm
auto	Try both AMD and MeTiS, pick best
metis	Use the MeTiS nested dissection algorithm (if available)

ma86_print_level (*integer*): Debug printing level for the linear solver MA86 [↔](#)

Range: $[-\infty, \infty]$

Default: -1

ma86_scaling (*string*): Controls scaling of matrix [↔](#)

This option controls scaling for the solver HSL_MA86.

Default: mc64

value	meaning
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]
none	Do not scale the linear system matrix

ma86_small (*real*): Zero Pivot Threshold [↔](#)

Any pivot less than ma86_small is treated as zero.

Default: 1e-20

ma86_static (*real*): Static Pivoting Threshold [↔](#)

See MA86 documentation. Either `ma86_static=0.0` or `ma86_static>ma86_small`. `ma86_static=0.0` disables static pivoting.

Default: 0

ma86_u (*real*): Pivoting Threshold [↔](#)

See MA86 documentation.

Range: $[0, 0.5]$

Default: 1e-08

ma86_umax (*real*): Maximum Pivoting Threshold [↔](#)

Maximum value to which u will be increased to improve quality.

Range: $[0, 0.5]$

Default: 0.0001

ma97_nemin (*integer*): Node Amalgamation parameter [↔](#)

Two nodes in elimination tree are merged if result has fewer than ma97_nemin variables.

Range: $[1, \infty]$

Default: 8

ma97_order (*string*): Controls type of ordering used by HSL_MA97 [↔](#)

Default: auto

value	meaning
amd	Use the HSL_MC68 approximate minimum degree algorithm
auto	Use HSL_MA97 heuristic to guess best of AMD and METIS
best	Try both AMD and MeTiS, pick best
matched-amd	Use the HSL_MC80 matching based ordering with AMD
matched-auto	Use the HSL_MC80 matching with heuristic choice of AMD or METIS
matched-metis	Use the HSL_MC80 matching based ordering with METIS
metis	Use the MeTiS nested dissection algorithm

ma97_print_level (*integer*): Debug printing level for the linear solver MA97 [↔](#)

Range: $[-\infty, \infty]$

Default: 0

ma97_scaling (*string*): Specifies strategy for scaling in HSL_MA97 linear solver [↔](#)

Default: `dynamic`

value	meaning
dynamic	Dynamically select scaling according to rules specified by <code>ma97_scalingX</code> and <code>ma97_switchX</code> options.
mc30	Scale all linear system matrices using MC30
mc64	Scale all linear system matrices using MC64
mc77	Scale all linear system matrices using MC77 [1,3,0]
none	Do not scale the linear system matrix

ma97_scaling1 (*string*): First scaling. [↔](#)

If `ma97_scaling=dynamic`, this scaling is used according to the trigger `ma97_switch1`. If `ma97_switch2` is triggered it is disabled.

Default: `mc64`

value	meaning
mc30	Scale linear system matrix using MC30
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]
none	No scaling

ma97_scaling2 (*string*): Second scaling. [↔](#)

If `ma97_scaling=dynamic`, this scaling is used according to the trigger `ma97_switch2`. If `ma97_switch3` is triggered it is disabled.

Default: `mc64`

value	meaning
mc30	Scale linear system matrix using MC30
mc64	Scale linear system matrix using MC64

value	meaning
mc77	Scale linear system matrix using MC77 [1,3,0]
none	No scaling

ma97_scaling3 (*string*): Third scaling. ↔

If ma97_scaling=dynamic, this scaling is used according to the trigger ma97_switch3.

Default: mc64

value	meaning
mc30	Scale linear system matrix using MC30
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]
none	No scaling

ma97_small (*real*): Zero Pivot Threshold ↔

Any pivot less than ma97_small is treated as zero.

Default: 1e-20

ma97_solve_blas3 (*string*): Controls if blas2 or blas3 routines are used for solve ↔

Default: no

value	meaning
no	Use BLAS2 (faster, some implementations bit incompatible)
yes	Use BLAS3 (slower)

ma97_switch1 (*string*): First switch, determine when ma97_scaling1 is enabled. ↔

If ma97_scaling=dynamic, ma97_scaling1 is enabled according to this condition. If ma97_switch2 occurs this option is henceforth ignored.

Default: od_hd_reuse

value	meaning
at_start	Scaling to be used from the very start.
at_start_reuse	Scaling to be used on first iteration, then reused thereafter.
high_delay	Scaling to be used after more than 0.05*n delays are present
high_delay_reuse	Scaling to be used only when previous itr created more that 0.05*n additional delays, otherwise reuse scaling from previous itr
never	Scaling is never enabled.
od_hd	Combination of on_demand and high_delay
od_hd_reuse	Combination of on_demand_reuse and high_delay_reuse
on_demand	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
on_demand_reuse	As on_demand, but reuse scaling from previous itr

ma97_switch2 (*string*): Second switch, determine when ma97_scaling2 is enabled. ↩

If ma97_scaling=dynamic, ma97_scaling2 is enabled according to this condition. If ma97_switch3 occurs this option is henceforth ignored.

Default: `never`

value	meaning
<code>at_start</code>	Scaling to be used from the very start.
<code>at_start_reuse</code>	Scaling to be used on first iteration, then reused thereafter.
<code>high_delay</code>	Scaling to be used after more than 0.05*n delays are present
<code>high_delay_reuse</code>	Scaling to be used only when previous itr created more that 0.05*n additional delays, otherwise reuse scaling from previous itr
<code>never</code>	Scaling is never enabled.
<code>od_hd</code>	Combination of <code>on_demand</code> and <code>high_delay</code>
<code>od_hd_reuse</code>	Combination of <code>on_demand_reuse</code> and <code>high_delay_reuse</code>
<code>on_demand</code>	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
<code>on_demand_reuse</code>	As <code>on_demand</code> , but reuse scaling from previous itr

ma97_switch3 (*string*): Third switch, determine when ma97_scaling3 is enabled. ↩

If ma97_scaling=dynamic, ma97_scaling3 is enabled according to this condition.

Default: `never`

value	meaning
<code>at_start</code>	Scaling to be used from the very start.
<code>at_start_reuse</code>	Scaling to be used on first iteration, then reused thereafter.
<code>high_delay</code>	Scaling to be used after more than 0.05*n delays are present
<code>high_delay_reuse</code>	Scaling to be used only when previous itr created more that 0.05*n additional delays, otherwise reuse scaling from previous itr
<code>never</code>	Scaling is never enabled.
<code>od_hd</code>	Combination of <code>on_demand</code> and <code>high_delay</code>
<code>od_hd_reuse</code>	Combination of <code>on_demand_reuse</code> and <code>high_delay_reuse</code>
<code>on_demand</code>	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
<code>on_demand_reuse</code>	As <code>on_demand</code> , but reuse scaling from previous itr

ma97_u (*real*): Pivoting Threshold ↩

See MA97 documentation.

Range: `[0, 0.5]`

Default: `1e-08`

ma97_umax (*real*): Maximum Pivoting Threshold ↩

See MA97 documentation.

Range: `[0, 0.5]`

Default: `0.0001`

maxmin_crit_have_sol (*real*): Weight towards minimum in of lower and upper branching estimates when a solution has been found. [↔](#)

Range: $[0, 1]$

Default: 0.1

maxmin_crit_no_sol (*real*): Weight towards minimum in of lower and upper branching estimates when no solution has been found yet. [↔](#)

Range: $[0, 1]$

Default: 0.7

max_consecutive_failures (*integer*): (temporarily removed) Number n of consecutive unsolved problems before aborting a branch of the tree. [↔](#)

When $n > 0$, continue exploring a branch of the tree until n consecutive problems in the branch are unsolved (we call unsolved a problem for which Ipopt can not guarantee optimality within the specified tolerances).

Default: 10

max_consecutive_infeasible (*integer*): Number of consecutive infeasible subproblems before aborting a branch. [↔](#)

Will continue exploring a branch of the tree until "max_consecutive_infeasible" consecutive problems are locally infeasible by the NLP sub-solver.

Default: 0

max_cpu_time (*real*): Maximum number of CPU seconds. [↔](#)

A limit on CPU seconds that Ipopt can use to solve one problem. If during the convergence check this limit is exceeded, Ipopt will terminate with a corresponding error message.

Default: 1e+06

max_fbbt_iter (*integer*): Number of FBBT iterations before stopping even with tightened bounds. [↔](#)

Set to -1 to impose no upper limit

Range: $[-1, \infty]$

Default: 3

max_filter_resets (*integer*): Maximal allowed number of filter resets [↔](#)

A positive number enables a heuristic that resets the filter, whenever in more than "filter_reset_trigger" successive iterations the last rejected trial steps size was rejected because of the filter. This option determine the maximal number of resets that are allowed to take place.

Default: 5

max_hessian_perturbation (*real*): Maximum value of regularization parameter for handling negative curvature. [↔](#)

In order to guarantee that the search directions are indeed proper descent directions, Ipopt requires that the inertia of the (augmented) linear system for the step computation has the correct number of negative and positive eigenvalues. The idea is that this guides the algorithm away from maximizers and makes Ipopt more likely converge to first order optimal points that are minimizers. If the inertia is not correct, a multiple of the identity matrix is added to the Hessian of the Lagrangian in the augmented system. This parameter gives the maximum value of the regularization parameter. If a regularization of that size is not enough, the algorithm skips this iteration and goes to the restoration phase. (This is $\delta w^{\max}$ in the implementation paper.)

Default: 1e+20

max_iter (*integer*): Maximum number of iterations. [↔](#)

The algorithm terminates with an error message if the number of iterations exceeded this number.

Default: 3000

max_random_point_radius (*real*): Set max value r for coordinate of a random point. [↔](#)

When picking a random point, coordinate i will be in the interval $[\min(\max(l, r), u - r), \max(\min(u, r), l + r)]$ (where l is the lower bound for the variable and u is its upper bound)

Default: 100000

max_refinement_steps (*integer*): Maximum number of iterative refinement steps per linear system solve. [↔](#)

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the maximum number of iterative refinement steps.

Default: 10

max_resto_iter (*integer*): Maximum number of successive iterations in restoration phase. [↔](#)

The algorithm terminates with an error message if the number of iterations successively taken in the restoration phase exceeds this number.

Default: 3000000

max_soc (*integer*): Maximum number of second order correction trial steps at each iteration. [↔](#)

Choosing 0 disables the second order corrections. (This is $p^{\max}$ of Step A-5.9 of Algorithm A in the implementation paper.)

Default: 4

max_soft_resto_iters (*integer*): Maximum number of iterations performed successively in soft restoration phase. [↔](#)

If the soft restoration phase is performed for more than so many iterations in a row, the regular restoration phase is called.

Default: 10

mehrotra_algorithm (*string*): Indicates if we want to do Mehrotra's algorithm. [↔](#)

If set to yes, Ipopt runs as Mehrotra's predictor-corrector algorithm. This works usually very well for LPs and convex QPs. This automatically disables the line search, and chooses the (unglobalized) adaptive μ strategy with the "probing" oracle, and uses "corrector_type=affine" without any safeguards; you should not set any of those options explicitly in addition. Also, unless otherwise specified, the values of "bound_push", "bound_frac", and "bound_mult_init_val" are set more aggressive, and sets "alpha_for_y=bound_mult".

Default: no

value	meaning
no	Do the usual Ipopt algorithm.
yes	Do Mehrotra's predictor-corrector algorithm.

milp_solver (*string*): Choose the subsolver to solve MILP sub-problems in OA decompositions. ↩

To use Cplex, a valid license is required.

Default: Cbc_D

value	meaning
cbc_d	Coin Branch and Cut with its default
cbc_par	Coin Branch and Cut with passed parameters
cplex	Cplex

milp_strategy (*string*): Choose a strategy for MILPs. ↩

Default: find_good_sol

value	meaning
find_good_sol	Stop sub milps when a solution improving the incumbent is found
solve_to_optimality	Solve MILPs to optimality

minlp_disj_cuts (*integer*): The frequency (in terms of nodes) at which Couenne disjunctive cuts are generated. ↩

A frequency of 0 (default) means these cuts are never generated. Any positive number n instructs Couenne to generate them at every n nodes of the B&B tree. A negative number $-n$ means that generation should be attempted at the root node, and if successful it can be repeated at every n nodes, otherwise it is stopped altogether.

Range: $[-99, \infty]$

Default: 0

min_hessian_perturbation (*real*): Smallest perturbation of the Hessian block. ↩

The size of the perturbation of the Hessian block is never selected smaller than this value, unless no perturbation is necessary. (This is $\delta_{w^{\min}}$ in implementation paper.)

Default: $1e-20$

min_number_strong_branch (*integer*): Sets minimum number of variables for strong branching (overriding trust) ↩

Default: 0

min_refinement_steps (*integer*): Minimum number of iterative refinement steps per linear system solve. ↩

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the minimum number of iterative refinements (i.e. at least "min_refinement_steps" iterative refinement steps are enforced per right hand side.)

Default: 1

mir_cuts (*integer*): Frequency k (in terms of nodes) for generating `mir_cuts` cuts in branch-and-cut. [↔](#)

See option `2mir_cuts` for the meaning of k .

Range: $[-100, \infty]$

Default: 0

multilinear_separation (*string*): Separation for multilinear terms [↔](#)

Type of separation for multilinear terms where the dependent variable is also bounded

Default: `tight`

value	meaning
<code>none</code>	No separation – just use the four McCormick inequalities
<code>simple</code>	Use one considering lower curve only
<code>tight</code>	Use one considering both curves $\pi(x) = l_{\{k+1\}}$ and $\pi(x) = u_{\{k+1\}}$

mumps_dep_tol (*real*): Pivot threshold for detection of linearly dependent constraints in MUMPS. [↔](#)

When MUMPS is used to determine linearly dependent constraints, this determines the threshold for a pivot to be considered zero. This is `CNTL(3)` in MUMPS.

Range: $[-\infty, \infty]$

Default: 0

mumps_mem_percent (*integer*): Percentage increase in the estimated working space for MUMPS. [↔](#)

In MUMPS when significant extra fill-in is caused by numerical pivoting, larger values of `mumps_mem_percent` may help use the workspace more efficiently. On the other hand, if memory requirements are too large at the very beginning of the optimization, choosing a much smaller value for this option, such as 5, might reduce memory requirements.

Default: 1000

mumps_permuting_scaling (*integer*): Controls permuting and scaling in MUMPS [↔](#)

This is `ICNTL(6)` in MUMPS.

Range: $[0, 7]$

Default: 7

mumps_pivot_order (*integer*): Controls pivot order in MUMPS [↔](#)

This is `ICNTL(7)` in MUMPS.

Range: $[0, 7]$

Default: 7

mumps_pivtol (*real*): Pivot tolerance for the linear solver MUMPS. [↔](#)

A smaller number pivots for sparsity, a larger number pivots for stability. This option is only available if Ipopt has been compiled with MUMPS.

Range: [0, 1]

Default: 1e-06

mumps_pivtolmax (*real*): Maximum pivot tolerance for the linear solver MUMPS. [↩](#)

Ipopt may increase pivtol as high as pivtolmax to get a more accurate solution to the linear system. This option is only available if Ipopt has been compiled with MUMPS.

Range: [0, 1]

Default: 0.1

mumps_scaling (*integer*): Controls scaling in MUMPS [↩](#)

This is ICNTL(8) in MUMPS.

Range: [-2, 77]

Default: 77

mu_allow_fast_monotone_decrease (*string*): Allow skipping of barrier problem if barrier test is already met. [↩](#)

If set to "no", the algorithm enforces at least one iteration per barrier problem, even if the barrier test is already met for the updated barrier parameter.

Default: yes

value	meaning
no	Take at least one iteration per barrier problem
yes	Allow fast decrease of mu if barrier test it met

mu_init (*real*): Initial value for the barrier parameter. [↩](#)

This option determines the initial value for the barrier parameter (mu). It is only relevant in the monotone, Fiacco-McCormick version of the algorithm. (i.e., if "mu_strategy" is chosen as "monotone")

Default: 0.1

mu_linear_decrease_factor (*real*): Determines linear decrease rate of barrier parameter. [↩](#)

For the Fiacco-McCormick update procedure the new barrier parameter mu is obtained by taking the minimum of $\mu * \text{mu\_linear\_decrease\_factor}$ and $\mu^{\text{superlinear\_decrease\_power}}$. (This is kappa.mu in implementation paper.) This option is also used in the adaptive mu strategy during the monotone mode.

Range: [0, 1]

Default: 0.2

mu_max (*real*): Maximum value for barrier parameter. [↩](#)

This option specifies an upper bound on the barrier parameter in the adaptive mu selection mode. If this option is set, it overwrites the effect of `mu_max_fact`. (Only used if option `"mu_strategy"` is chosen as `"adaptive"`.)

Default: 100000

mu_max_fact (*real*): Factor for initialization of maximum value for barrier parameter. [↔](#)

This option determines the upper bound on the barrier parameter. This upper bound is computed as the average complementarity at the initial point times the value of this option. (Only used if option `"mu_strategy"` is chosen as `"adaptive"`.)

Default: 1000

mu_min (*real*): Minimum value for barrier parameter. [↔](#)

This option specifies the lower bound on the barrier parameter in the adaptive mu selection mode. By default, it is set to the minimum of $1e-11$ and $\min(\text{"tol"}, \text{"compl\_inf\_tol"})/(\text{"barrier\_tol\_factor"}+1)$, which should be a reasonable value. (Only used if option `"mu_strategy"` is chosen as `"adaptive"`.)

Default: $1e-11$

mu_oracle (*string*): Oracle for a new barrier parameter in the adaptive strategy. [↔](#)

Determines how a new barrier parameter is computed in each `"free-mode"` iteration of the adaptive barrier parameter strategy. (Only considered if `"adaptive"` is selected for option `"mu_strategy"`).

Default: `quality-function`

value	meaning
<code>loqo</code>	LOQO's centrality rule
<code>probing</code>	Mehrotra's probing heuristic
<code>quality-function</code>	minimize a quality function

mu_strategy (*string*): Update strategy for barrier parameter. [↔](#)

Determines which barrier parameter update strategy is to be used.

Default: `monotone`

value	meaning
<code>adaptive</code>	use the adaptive update strategy
<code>monotone</code>	use the monotone (Fiacco-McCormick) strategy

mu_superlinear_decrease_power (*real*): Determines superlinear decrease rate of barrier parameter. [↔](#)

For the Fiacco-McCormick update procedure the new barrier parameter μ is obtained by taking the minimum of $\mu * \text{mu\_linear\_decrease\_factor}$ and $\mu^{\text{mu\_superlinear\_decrease\_power}}$. (This is `theta_mu` in implementation paper.) This option is also used in the adaptive mu strategy during the monotone mode.

Range: $[1, 2]$

Default: 1.5

mu_target (*real*): Desired value of complementarity. [↔](#)

Usually, the barrier parameter is driven to zero and the termination test for complementarity is measured with respect to zero complementarity. However, in some cases it might be desired to have Ipopt solve barrier problem for strictly positive value of the barrier parameter. In this case, the value of "mu_target" specifies the final value of the barrier parameter, and the termination tests are then defined with respect to the barrier problem for this value of the barrier parameter.

Default: 0

neg_curv_test_reg (*string*): Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014). [↔](#)

Default: **yes**

value	meaning
no	use original IPOPT approach, in which the primal regularization is ignored
yes	use primal regularization with the inertia-free curvature test

neg_curv_test_tol (*real*): Tolerance for heuristic to ignore wrong inertia. [↔](#)

If nonzero, incorrect inertia in the augmented system is ignored, and Ipopt tests if the direction is a direction of positive curvature. This tolerance is α_n in the paper by Zavala and Chiang (2014) and it determines when the direction is considered to be sufficiently positive. A value in the range of [1e-12, 1e-11] is recommended.

Default: 0

nlpheur_print_level (*integer*): Output level for NLP heuristic in Couenne [↔](#)

Range: [-2, 12]

Default: 0

nlp_failure_behavior (*string*): Set the behavior when an NLP or a series of NLP are unsolved by Ipopt (we call unsolved an NLP for which Ipopt is not able to guarantee optimality within the specified tolerances). [↔](#)

If set to "fathom", the algorithm will fathom the node when Ipopt fails to find a solution to the nlp at that node within the specified tolerances. The algorithm then becomes a heuristic, and the user will be warned that the solution might not be optimal.

Default: **stop**

value	meaning
fathom	Continue when failure happens.
stop	Stop when failure happens.

nlp_log_at_root (*integer*): specify a different log level for root relaxation. [↔](#)

Range: [0, 12]

Default: 0

nlp_log_level (*integer*): specify NLP solver interface log level (independent from ipopt print_level). ↩

Set the level of output of the OsiTMINLPInterface : 0 - none, 1 - normal, 2 - verbose

Range: [0, 2]

Default: 1

nlp_scaling_constr_target_gradient (*real*): Target value for constraint function gradient size. ↩

If a positive number is chosen, the scaling factor the constraint functions is computed so that the gradient has the max norm of the given size at the starting point. This overrides nlp_scaling_max_gradient for the constraint functions.

Default: 0

nlp_scaling_max_gradient (*real*): Maximum gradient after NLP scaling. ↩

This is the gradient scaling cut-off. If the maximum gradient is above this value, then gradient based scaling will be performed. Scaling parameters are calculated to scale the maximum gradient back to this value. (This is g_max in Section 3.8 of the implementation paper.) Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Default: 100

nlp_scaling_method (*string*): Select the technique used for scaling the NLP. ↩

Selects the technique used for scaling the problem internally before it is solved. For user-scaling, the parameters come from the NLP. If you are using AMPL, they can be specified through suffixes ("scaling_factor")

Default: gradient-based

value	meaning
equilibration-based	scale the problem so that first derivatives are of order 1 at random points (only available with MC19)
gradient-based	scale the problem so the maximum gradient at the starting point is scaling_max_gradient
none	no problem scaling will be performed

nlp_scaling_min_value (*real*): Minimum value of gradient-based scaling values. ↩

This is the lower bound for the scaling factors computed by gradient-based scaling method. If some derivatives of some functions are huge, the scaling factors will otherwise become very small, and the (unscaled) final constraint violation, for example, might then be significant. Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Default: 1e-08

nlp_scaling_obj_target_gradient (*real*): Target value for objective function gradient size. ↩

If a positive number is chosen, the scaling factor the objective function is computed so that the gradient has the max norm of the given size at the starting point. This overrides nlp_scaling_max_gradient for the objective function.

Default: 0

node_comparison (*string*): Choose the node selection strategy. ↩

Choose the strategy for selecting the next node to be processed.

Default: `best-bound`

value	meaning
<code>best-bound</code>	choose node with the smallest bound,
<code>best-guess</code>	choose node with smallest guessed integer solution
<code>breadth-first</code>	Perform breadth first search,
<code>depth-first</code>	Perform depth first search,
<code>dynamic</code>	Cbc dynamic strategy (starts with a depth first search and turn to best bound after 3 integer feasible solutions have been found).

node_limit (*integer*): Set the maximum number of nodes explored in the branch-and-bound search. ↩

Default: `maxint`

number_before_trust (*integer*): Set the number of branches on a variable before its pseudo costs are to be believed in dynamic strong branching. ↩

A value of 0 disables pseudo costs.

Default: 8

number_before_trust_list (*integer*): Set the number of branches on a variable before its pseudo costs are to be believed during setup of strong branching candidate list. ↩

The default value is that of "number_before_trust"

Range: $[-1, \infty]$

Default: 0

number_look_ahead (*integer*): Sets limit of look-ahead strong-branching trials ↩

Default: 0

number_strong_branch (*integer*): Choose the maximum number of variables considered for strong branching. ↩

Set the number of variables on which to do strong branching.

Default: 20

number_strong_branch_root (*integer*): Maximum number of variables considered for strong branching in root node. ↩

Default: `maxint`

num_cut_passes (*integer*): Set the maximum number of cut passes at regular nodes of the branch-and-cut. ↩

Default: 1

num_cut_passes_at_root (*integer*): Set the maximum number of cut passes at regular nodes of the branch-and-cut. ↩

Default: 20

num_iterations_suspect (*integer*): Number of iterations over which a node is considered 'suspect' (for debugging purposes only, see detailed documentation). [↔](#)

When the number of iterations to solve a node is above this number, the subproblem at this node is considered to be suspect and it will be written into a file (set to -1 to deactivate this).

Range: $[-1, \infty]$

Default: -1

num_resolve_at_infeasibles (*integer*): Number k of tries to resolve an infeasible node (other than the root) of the tree with different starting point. [↔](#)

The algorithm will solve all the infeasible nodes with k different random starting points and will keep the best local optimum found.

Default: 0

num_resolve_at_node (*integer*): Number k of tries to resolve a node (other than the root) of the tree with different starting point. [↔](#)

The algorithm will solve all the nodes with k different random starting points and will keep the best local optimum found.

Default: 0

num_resolve_at_root (*integer*): Number k of tries to resolve the root node with different starting points. [↔](#)

The algorithm will solve the root node with k random starting points and will keep the best local optimum found.

Default: 0

num_retry_unsolved_random_point (*integer*): Number k of times that the algorithm will try to resolve an unsolved NLP with a random starting point (we call unsolved an NLP for which Ipopt is not able to guarantee optimality within the specified tolerances). [↔](#)

When Ipopt fails to solve a continuous NLP sub-problem, if $k > 0$, the algorithm will try again to solve the failed NLP with k new randomly chosen starting points or until the problem is solved with success.

Default: 0

nu_inc (*real*): Increment of the penalty parameter. [↔](#)

Default: 0.0001

nu_init (*real*): Initial value of the penalty parameter. [↔](#)

Default: 1e-06

oa_cuts_log_level (*integer*): level of log when generating OA cuts. [↔](#)

0: outputs nothing, 1: when a cut is generated, its violation and index of row from which it originates, 2: always output violation of the cut. 3: output generated cuts incidence vectors.

Default: 0

oa_cuts_scope (*string*): Specify if OA cuts added are to be set globally or locally valid [↔](#)

Default: global

value	meaning
global	Cuts are treated as globally valid
local	Cuts are treated as locally valid

oa_rhs_relax (*real*): Value by which to relax OA cut ↩

RHS of OA constraints will be relaxed by this amount times the absolute value of the initial rhs if it is ≥ 1 (otherwise by this amount).

Default: `1e-08`

obj_max_inc (*real*): Determines the upper bound on the acceptable increase of barrier objective function. ↩

Trial points are rejected if they lead to an increase in the barrier objective function by more than `obj_max_inc` orders of magnitude.

Range: $[1, \infty]$

Default: `5`

optimality_bt (*string*): Optimality-based (expensive) bound tightening (OBBT) ↩

This is another bound reduction technique aiming at reducing the solution set by looking at the initial LP relaxation. This technique is computationally expensive, and should be used only when necessary.

Default: `yes`

Values: `no`, `yes`

orbital_branching (*string*): detect symmetries and apply orbital branching ↩

Default: `no`

Values: `no`, `yes`

orbital_branching_depth (*integer*): Maximum depth at which the symmetry group is computed ↩

Select -1 if you want to compute the symmetry group at all nodes

Range: $[-1, \infty]$

Default: `10`

output_level (*integer*): Output level ↩

Range: $[-2, 12]$

Default: `4`

pardiso_matching_strategy (*string*): Matching strategy to be used by Pardiso ↩

This is IPAR(13) in Pardiso manual.

Default: `complete+2x2`

value	meaning
complete	Match complete (IPAR(13)=1)
complete+2x2	Match complete+2x2 (IPAR(13)=2)
constraints	Match constraints (IPAR(13)=3)

pardiso_max_iterative_refinement_steps (*integer*): Limit on number of iterative refinement steps. [↔](#)

The solver does not perform more than the absolute value of this value steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. If negative, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement. The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and this option is set to 0.

Range: $[-\infty, \infty]$

Default: 1

pardiso_msglvl (*integer*): Pardiso message level [↔](#)

This determines the amount of analysis output from the Pardiso solver. This is MSGVLV in the Pardiso manual.

Default: 0

pardiso_order (*string*): Controls the fill-in reduction ordering algorithm for the input matrix. [↔](#)

Default: metis

value	meaning
amd	minimum degree algorithm
metis	MeTiS nested dissection algorithm
one	undocumented
pmetis	parallel (OpenMP) version of MeTiS nested dissection algorithm

pardiso_redo_symbolic_fact_only_if_inertia_wrong (*string*): Toggle for handling case when elements were perturbed by Pardiso. [↔](#)

Default: no

value	meaning
no	Always redo symbolic factorization when elements were perturbed
yes	Only redo symbolic factorization when elements were perturbed if also the inertia was wrong

pardiso_repeated_perturbation_means_singular (*string*): Interpretation of perturbed elements. [↔](#)

Default: no

value	meaning
no	Don't assume that matrix is singular if elements were perturbed after recent symbolic factorization

value	meaning
yes	Assume that matrix is singular if elements were perturbed after recent symbolic factorization

pardiso_skip_inertia_check (*string*): Always pretend inertia is correct. [↔](#)

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Default: no

value	meaning
no	check inertia
yes	skip inertia check

perturb_always_cd (*string*): Active permanent perturbation of constraint linearization. [↔](#)

This options makes the delta_c and delta_d perturbation be used for the computation of every search direction. Usually, it is only used when the iteration matrix is singular.

Default: no

value	meaning
no	perturbation only used when required
yes	always use perturbation

perturb_dec_fact (*real*): Decrease factor for x-s perturbation. [↔](#)

The factor by which the perturbation is decreased when a trial value is deduced from the size of the most recent successful perturbation. (This is κ_w^- in the implementation paper.)

Range: [0, 1]

Default: 0.333333

perturb_inc_fact (*real*): Increase factor for x-s perturbation. [↔](#)

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of all perturbations except for the first. (This is κ_w^+ in the implementation paper.)

Range: [1, ∞]

Default: 8

perturb_inc_fact_first (*real*): Increase factor for x-s perturbation for very first perturbation. [↔](#)

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of the very first perturbation and allows a different value for for the first perturbation than that used for the remaining perturbations. (This is $\bar{\kappa}_w^+$ in the implementation paper.)

Range: [1, ∞]

Default: 100

print_eval_error (*string*): Switch to enable printing information about function evaluation errors into the GAMS listing file. ↩

Default: **yes**

Values: **no**, **yes**

print_frequency_iter (*integer*): Determines at which iteration frequency the summarizing iteration output line should be printed. ↩

Summarizing iteration output is printed every `print_frequency_iter` iterations, if at least `print_frequency_time` seconds have passed since last output.

Range: $[1, \infty]$

Default: **1**

print_frequency_time (*real*): Determines at which time frequency the summarizing iteration output line should be printed. ↩

Summarizing iteration output is printed if at least `print_frequency_time` seconds have passed since last output and the iteration number is a multiple of `print_frequency_iter`.

Default: **0**

print_info_string (*string*): Enables printing of additional info string at end of iteration output. ↩

This string contains some insider information about the current iteration. For details, look for "Diagnostic Tags" in the Ipopt documentation.

Default: **no**

value	meaning
no	don't print string
yes	print string at end of each iteration output

print_level (*integer*): Output verbosity level. ↩

Sets the default verbosity level for console output. The larger this value the more detailed is the output.

Range: $[0, 12]$

Default: **5**

print_timing_statistics (*string*): Switch to print timing statistics. ↩

If selected, the program will print the CPU usage (user time) for selected tasks.

Default: **no**

value	meaning
no	don't print statistics
yes	print all timing statistics

probing_cuts (*integer*): Frequency k (in terms of nodes) for generating probing_cuts cuts in branch-and-cut. [↔](#)

See option **2mir_cuts** for the meaning of k .

Range: $[-100, \infty]$

Default: 0

problem_print_level (*integer*): Output level for problem manipulation code in Couenne [↔](#)

Range: $[-2, 12]$

Default: 2

pseudocost_mult (*string*): Multipliers of pseudocosts for estimating and update estimation of bound [↔](#)

Default: **interval_br_rev**

value	meaning
infeasibility	infeasibility returned by object
interval_br	width of the interval between bound and branching point
interval_br_rev	similar to interval_br, reversed
interval_lp	width of the interval between bound and current lp point
interval_lp_rev	similar to interval_lp, reversed
projectdist	distance between current LP point and resulting branches' LP points

pseudocost_mult_lp (*string*): Use distance between LP points to update multipliers of pseudocosts after simulating branching [↔](#)

Default: **no**

Values: **no**, **yes**

pump_for_minlp (*string*): whether to run the feasibility pump heuristic for MINLP [↔](#)

Default: **no**

Values: **no**, **yes**

quadrilinear_decomp (*string*): type of decomposition for quadrilinear terms (see work by Cafieri, Lee, Liberti) [↔](#)

Default: **raI**

value	meaning
bi+tri	Bilinear, THEN trilinear term: $x_5 = ((x_1 \ x_2) \ x_3 \ x_4)$
hier-bi	Hierarchical decomposition: $x_5 = ((x_1 \ x_2) \ (x_3 \ x_4))$
rai	Recursive decomposition in bilinear terms (as in Ryoo and Sahinidis): $x_5 = ((x_1 \ x_2) \ x_3) \ x_4$
tri+bi	Trilinear and bilinear term: $x_5 = (x_1 \ (x_2 \ x_3 \ x_4))$

quality_function_balancing_term (*string*): The balancing term included in the quality function for

centrality. ↩

This determines whether a term is added to the quality function that penalizes situations where the complementarity is much smaller than dual and primal infeasibilities. (Only used if option "mu_oracle" is set to "quality-function".)

Default: none

value	meaning
cubic	$\text{Max}(0, \text{Max}(\text{dual\_inf}, \text{primal\_inf}) - \text{compl})^3$
none	no balancing term is added

quality_function_centrality (*string*): The penalty term for centrality that is included in quality function. ↩

This determines whether a term is added to the quality function to penalize deviation from centrality with respect to complementarity. The complementarity measure here is the xi in the Logo update rule. (Only used if option "mu_oracle" is set to "quality-function".)

Default: none

value	meaning
cubed-reciprocal	complementarity * the reciprocal of the centrality measure cubed
log	complementarity * the log of the centrality measure
none	no penalty term is added
reciprocal	complementarity * the reciprocal of the centrality measure

quality_function_max_section_steps (*integer*): Maximum number of search steps during direct search procedure determining the optimal centering parameter. ↩

The golden section search is performed for the quality function based mu oracle. (Only used if option "mu_oracle" is set to "quality-function".)

Default: 8

quality_function_norm_type (*string*): Norm used for components of the quality function. ↩

(Only used if option "mu_oracle" is set to "quality-function".)

Default: 2-norm-squared

value	meaning
1-norm	use the 1-norm (abs sum)
2-norm	use 2-norm
2-norm-squared	use the 2-norm squared (sum of squares)
max-norm	use the infinity norm (max)

quality_function_section_qf_tol (*real*): Tolerance for the golden section search procedure determining the optimal centering parameter (in the function value space). ↩

The golden section search is performed for the quality function based mu oracle. (Only used if option "mu_oracle" is set to "quality-function".)

Range: $[0, 1]$

Default: 0

quality_function_section_sigma_tol (*real*): Tolerance for the section search procedure determining the optimal centering parameter (in sigma space). [↔](#)

The golden section search is performed for the quality function based mu oracle. (Only used if option "mu_oracle" is set to "quality-function".)

Range: $[0, 1]$

Default: 0.01

random_generator_seed (*integer*): Set seed for random number generator (a value of -1 sets seeds to time since Epoch). [↔](#)

Range: $[-1, \infty]$

Default: 0

random_point_perturbation_interval (*real*): Amount by which starting point is perturbed when choosing to pick random point by perturbing starting point [↔](#)

Default: 1

random_point_type (*string*): method to choose a random starting point [↔](#)

Default: Jon

value	meaning
andreas	perturb the starting point of the problem within a prescribed interval
claudia	perturb the starting point using the perturbation radius suffix information
jon	Choose random point uniformly between the bounds

read_solution_file (*string*): Read a file with the optimal solution to test if algorithms cuts it. [↔](#)

For Debugging purposes only.

Default: no

Values: no, yes

recalc_y (*string*): Tells the algorithm to recalculate the equality and inequality multipliers as least square estimates. [↔](#)

This asks the algorithm to recompute the multipliers, whenever the current infeasibility is less than `recalc_y_feas_tol`. Choosing yes might be helpful in the quasi-Newton option. However, each recalculation requires an extra factorization of the linear system. If a limited memory quasi-Newton option is chosen, this is used by default.

Default: no

value	meaning
no	use the Newton step to update the multipliers
yes	use least-square multiplier estimates

recalc_y_feas_tol (*real*): Feasibility threshold for recomputation of multipliers. [↔](#)

If `recalc_y` is chosen and the current infeasibility is less than this value, then the multipliers are recomputed.

Default: `1e-06`

redcost_bt (*string*): Reduced cost bound tightening [↔](#)

This bound reduction technique uses the reduced costs of the LP in order to infer better variable bounds.

Default: `yes`

Values: `no`, `yes`

reduce_split_cuts (*integer*): Frequency `k` (in terms of nodes) for generating `reduce_split_cuts` cuts in branch-and-cut. [↔](#)

See option `2mir_cuts` for the meaning of `k`.

Range: $[-100, \infty]$

Default: `0`

red_cost_branching (*string*): Apply Reduced Cost Branching (instead of the Violation Transfer) – MUST have `vt_obj` enabled [↔](#)

Default: `no`

value	meaning
<code>no</code>	Use Violation Transfer with $\sum \ \pi_i a_{ij}\ $
<code>yes</code>	Use Reduced cost branching with $\ \sum \pi_i a_{ij}\ $

reformulate_print_level (*integer*): Output level for reformulating problems in Couenne [↔](#)

Range: $[-2, 12]$

Default: `0`

replace_bounds (*string*): Indicates if all variable bounds should be replaced by inequality constraints [↔](#)

This option must be set for the inexact algorithm

Default: `no`

value	meaning
<code>no</code>	leave bounds on variables
<code>yes</code>	replace variable bounds by inequality constraints

required_infeasibility_reduction (*real*): Required reduction of infeasibility before leaving restoration phase. [↔](#)

The restoration phase algorithm is performed, until a point is found that is acceptable to the filter and the infeasibility has been reduced by at least the fraction given by this option.

Range: $[0, 1]$

Default: 0.9

residual_improvement_factor (*real*): Minimal required reduction of residual test ratio in iterative refinement. [↔](#)

If the improvement of the residual test ratio made by one iterative refinement step is not better than this factor, iterative refinement is aborted.

Default: 1

residual_ratio_max (*real*): Iterative refinement tolerance [↔](#)

Iterative refinement is performed until the residual test ratio is less than this tolerance (or until "max_refinement_steps" refinement steps are performed).

Default: $1e-10$

residual_ratio_singular (*real*): Threshold for declaring linear system singular after failed iterative refinement. [↔](#)

If the residual test ratio is larger than this value after failed iterative refinement, the algorithm pretends that the linear system is singular.

Default: $1e-05$

resolve_on_small_infeasibility (*real*): If a locally infeasible problem is infeasible by less than this, resolve it with initial starting point. [↔](#)

Default: 0

resto_failure_feasibility_threshold (*real*): Threshold for primal infeasibility to declare failure of restoration phase. [↔](#)

If the restoration phase is terminated because of the "acceptable" termination criteria and the primal infeasibility is smaller than this value, the restoration phase is declared to have failed. The default value is $1e2 * tol$, where tol is the general termination tolerance.

Default: 0

resto_penalty_parameter (*real*): Penalty parameter in the restoration phase objective function. [↔](#)

This is the parameter ρ in equation (31a) in the Ipopt implementation paper.

Default: 1000

resto_proximity_weight (*real*): Weighting factor for the proximity term in restoration phase objective. [↔](#)

This determines how the parameter ζ in equation (29a) in the implementation paper is computed. ζ here is $resto\_proximity\_weight * \sqrt{\mu}$, where μ is the current barrier parameter.

Default: 1

rho (*real*): Value in penalty parameter update formula. [↔](#)

Range: $[0, 1]$

Default: 0.1

sdp_cuts (*integer*): The frequency (in terms of nodes) at which Couenne SDP cuts are generated. [↔](#)

A frequency of 0 (default) means these cuts are never generated. Any positive number n instructs Couenne to generate them at every n nodes of the B&B tree. A negative number $-n$ means that generation should be attempted at the root node, and if successful it can be repeated at every n nodes, otherwise it is stopped altogether.

Range: $[-99, \infty]$

Default: 0

sdp_cuts_fillmissing (*string*): Create fictitious auxiliary variables to fill non-fully dense minors. Can make a difference when Q has at least one zero term. [↔](#)

Default: no

value	meaning
no	Do not create auxiliaries and simply use Fourier-Motzkin to substitute a missing auxiliary y_{ij} with inequalities that use bounds and the definition $y_{ij} = x_i x_j$. Advantage: limits the creation of auxiliaries, reformulation stays small. Default.
yes	Create (at the beginning) auxiliaries that are linearized (through McCormick) and used within an SDP cut. This allows tighter cuts although it increases the size of the reformulation and hence of the linear relaxation.

sdp_cuts_neg_ev (*string*): Only use negative eigenvalues to create sdp cuts. [↔](#)

Default: **yes**

value	meaning
no	use all eigenvalues regardless of their sign.
yes	exclude all non-negative eigenvalues.

sdp_cuts_num_ev (*integer*): The number of eigenvectors of matrix X to be used to create sdp cuts. [↔](#)

Set to -1 to indicate that all n eigenvectors should be used. Eigenvalues are sorted in non-decreasing order, hence selecting 1 will provide cuts on the most negative eigenvalue.

Range: $[-1, \infty]$

Default: -1

sdp_cuts_sparsify (*string*): Make cuts sparse by greedily reducing X one column at a time before extracting eigenvectors. [↔](#)

Default: **no**

Values: **no**, **yes**

second_perc_for_cutoff_decr (*real*): The percentage used when, the coeff of variance is greater than the threshold, to compute the cutoff_decr dynamically. [↔](#)

Range: $[-\infty, \infty]$

Default: -0.05

setup_pseudo_frac (*real*): Proportion of strong branching list that has to be taken from most-integer-infeasible list. [↔](#)

Range: $[0, 1]$

Default: 0.5

sigma_max (*real*): Maximum value of the centering parameter. [↔](#)

This is the upper bound for the centering parameter chosen by the quality function based barrier parameter update. (Only used if option "mu_oracle" is set to "quality-function".)

Default: 100

sigma_min (*real*): Minimum value of the centering parameter. [↔](#)

This is the lower bound for the centering parameter chosen by the quality function based barrier parameter update. (Only used if option "mu_oracle" is set to "quality-function".)

Default: 1e-06

skip_corr_if_neg_curv (*string*): Skip the corrector step in negative curvature iteration. [↔](#)

The corrector step is not tried if negative curvature has been encountered during the computation of the search direction in the current iteration. This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Default: **yes**

value	meaning
no	don't skip
yes	skip

skip_corr_in_monotone_mode (*string*): Skip the corrector step during monotone barrier parameter mode. [↔](#)

The corrector step is not tried if the algorithm is currently in the monotone mode (see also option "barrier_strategy"). This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Default: yes

value	meaning
no	don't skip
yes	skip

slack_bound_frac (*real*): Desired minimum relative distance from the initial slack to bound. [↔](#)

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_push"). (This is kappa_2 in Section 3.6 of implementation paper.)

Range: [0, 0.5]

Default: 0.01

slack_bound_push (*real*): Desired minimum absolute distance from the initial slack to bound. [↔](#)

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)

Default: 0.01

slack_move (*real*): Correction size for very small slacks. [↔](#)

Due to numerical issues or the lack of an interior, the slack variables might become very small. If a slack becomes very small compared to machine precision, the corresponding bound is moved slightly. This parameter determines how large the move should be. Its default value is $\text{mach\_eps}^{\{3/4\}}$. (See also end of Section 3.5 in implementation paper - but actual implementation might be somewhat different.)

Default: 1.81899e-12

soc_method (*integer*): Ways to apply second order correction [↔](#)

This option determines the way to apply second order correction, 0 is the method described in the implementation paper. 1 is the modified way which adds alpha on the rhs of x and s rows.

Range: [0, 1]

Default: 0

soft_resto_pderror_reduction_factor (*real*): Required reduction in primal-dual error in the soft restoration phase. ↩

The soft restoration phase attempts to reduce the primal-dual error with regular steps. If the damped primal-dual step (damped only to satisfy the fraction-to-the-boundary rule) is not decreasing the primal-dual error by at least this factor, then the regular restoration phase is called. Choosing "0" here disables the soft restoration phase.

Default: 0.9999

solution_limit (*integer*): Abort after that much integer feasible solution have been found by algorithm ↩

value 0 deactivates option

Default: `maxint`

solvetrace (*string*): Name of file for writing solving progress information. ↩

solvetracenodefreq (*integer*): Frequency in number of nodes for writing solving progress information. ↩

giving 0 disables writing of N-lines to trace file

Default: 100

solvetracetimefreq (*real*): Frequency in seconds for writing solving progress information. ↩

giving 0.0 disables writing of T-lines to trace file

Default: 5

start_with_resto (*string*): Tells algorithm to switch to restoration phase in first iteration. ↩

Setting this option to "yes" forces the algorithm to switch to the feasibility restoration phase in the first iteration. If the initial point is feasible, the algorithm will abort with a failure.

Default: `no`

value	meaning
<code>no</code>	don't force start in restoration phase
<code>yes</code>	force start in restoration phase

s_max (*real*): Scaling threshold for the NLP error. ↩

(See paragraph after Eqn. (6) in the implementation paper.)

Default: 100

s_phi (*real*): Exponent for linear barrier function model in the switching rule. ↩

(See Eqn. (19) in the implementation paper.)

Range: $[1, \infty]$

Default: 2.3

s_theta (*real*): Exponent for current constraint violation in the switching rule. [↔](#)

(See Eqn. (19) in the implementation paper.)

Range: $[1, \infty]$

Default: 1.1

tau_min (*real*): Lower bound on fraction-to-the-boundary parameter tau. [↔](#)

(This is tau_min in the implementation paper.) This option is also used in the adaptive mu strategy during the monotone mode.

Range: $[0, 1]$

Default: 0.99

theta_max_fact (*real*): Determines upper bound for constraint violation in the filter. [↔](#)

The algorithmic parameter theta_max is determined as theta_max_fact times the maximum of 1 and the constraint violation at initial point. Any point with a constraint violation larger than theta_max is unacceptable to the filter (see Eqn. (21) in the implementation paper).

Default: 10000

theta_min_fact (*real*): Determines constraint violation threshold in the switching rule. [↔](#)

The algorithmic parameter theta_min is determined as theta_min_fact times the maximum of 1 and the constraint violation at initial point. The switching rules treats an iteration as an h-type iteration whenever the current constraint violation is larger than theta_min (see paragraph before Eqn. (19) in the implementation paper).

Default: 0.0001

time_limit (*real*): Set the global maximum computation time (in secs) for the algorithm. [↔](#)

Default: 1000

tiny_element (*real*): Value for tiny element in OA cut [↔](#)

We will remove "cleanly" (by relaxing cut) an element lower than this.

Default: 1e-08

tiny_step_tol (*real*): Tolerance for detecting numerically insignificant steps. [↔](#)

If the search direction in the primal variables (x and s) is, in relative terms for each component, less than this value, the algorithm accepts the full step without line search. If this happens repeatedly, the algorithm will terminate with a corresponding exit message. The default value is 10 times machine precision.

Default: 2.22045e-15

tiny_step_y_tol (*real*): Tolerance for quitting because of numerically insignificant steps. [↔](#)

If the search direction in the primal variables (x and s) is, in relative terms for each component, repeatedly less than tiny_step_tol, and the step in the y variables is smaller than this threshold, the algorithm will terminate.

Default: 0.01

tol (*real*): Desired convergence tolerance (relative). ↩

Determines the convergence tolerance for the algorithm. The algorithm terminates successfully, if the (scaled) NLP error becomes smaller than this value, and if the (absolute) criteria according to "dual_inf_tol", "constr_viol_tol", and "compl_inf_tol" are met. (This is epsilon_tol in Eqn. (6) in implementation paper). See also "acceptable_tol" as a second termination criterion. Note, some other algorithmic features also use this quantity to determine thresholds etc.

Default: 1e-08

tree_search_strategy (*string*): Pick a strategy for traversing the tree ↩

All strategies can be used in conjunction with any of the node comparison functions. Options which affect dfs-dive are max-backtracks-in-dive and max-dive-depth. The dfs-dive won't work in a non-convex problem where objective does not decrease down branches.

Default: probed-dive

value	meaning
dfs-dive	Dive in the tree if possible doing a depth first search. Backtrack on leaves or when a prescribed depth is attained or when estimate of best possible integer feasible solution in subtree is worst than cutoff.
dfs-dive-dynamic	Same as dfs-dive but once enough solution are found switch to best-bound and if too many nodes switch to depth-first.
dive	Dive in the tree if possible, otherwise pick top node as sorted by the tree comparison function.
probed-dive	Dive in the tree exploring two children before continuing the dive at each level.
top-node	Always pick the top node as sorted by the node comparison function

trust_strong (*string*): Fathom strong branching LPs when their bound is above the cutoff ↩

Default: yes

Values: no, yes

trust_strong_branching_for_pseudo_cost (*string*): Whether or not to trust strong branching results for updating pseudo costs. ↩

Default: yes

Values: no, yes

twoimpl_depth_level (*integer*): Depth of the B&B tree when to start decreasing the chance of running this algorithm. ↩

This has a similar behavior as log_num_obbt_per_level. A value of -1 means that generation can be done at all nodes.

Range: [-1, ∞]

Default: 5

twoimpl_depth_stop (*integer*): Depth of the B&B tree where separation is stopped. ↩

A value of -1 means that generation can be done at all nodes

Range: $[-1, \infty]$

Default: 20

two_implied_bt (*integer*): The frequency (in terms of nodes) at which Couenne two-implied bounds are tightened. [↔](#)

A frequency of 0 (default) means these cuts are never generated. Any positive number n instructs Couenne to generate them at every n nodes of the B&B tree. A negative number $-n$ means that generation should be attempted at the root node, and if successful it can be repeated at every n nodes, otherwise it is stopped altogether.

Range: $[-99, \infty]$

Default: 0

two_implied_max_trials (*integer*): The number of iteration at each call to the cut generator. [↔](#)

Range: $[1, \infty]$

Default: 2

use_auxcons (*string*): Use constraints-defined auxiliaries, i.e. auxiliaries $w = f(x)$ defined by original constraints $f(x) - w = 0$ [↔](#)

Default: **yes**

Values: **no**, **yes**

use_quadratic (*string*): Use quadratic expressions and related `exprQuad` class [↔](#)

If enabled, then quadratic forms are not reformulated and therefore decomposed as a sum of auxiliary variables, each associated with a bilinear term, but rather taken as a whole expression. Envelopes for these expressions are generated through alpha-convexification.

Default: **no**

value	meaning
no	Use an auxiliary for each bilinear term
yes	Create only one auxiliary for a quadratic expression

use_semiaux (*string*): Use semiauxiliaries, i.e. auxiliaries defined as $w \geq f(x)$ rather than $w := f(x)$ [↔](#)

Default: **yes**

value	meaning
no	Only use auxiliaries assigned with '='
yes	Use auxiliaries defined by $w \leq f(x)$, $w \geq f(x)$, and $w = f(x)$

variable_selection (*string*): Chooses variable selection strategy [↔](#)

Default: **strong-branching**

value	meaning
lp-strong-branching	Perform strong branching with LP approximation
most-fractional	Choose most fractional variable
nlp-strong-branching	Perform strong branching with NLP approximation
osi-simple	Osi method to do simple branching
osi-strong	Osi method to do strong branching
qp-strong-branching	Perform strong branching with QP approximation
random	Method to choose branching variable randomly
reliability-branching	Use reliability branching
strong-branching	Perform strong branching

very_tiny_element (*real*): Value for very tiny element in OA cut ↩

Algorithm will take the risk of neglecting an element lower than this.

Default: 1e-17

violated_cuts_only (*string*): Yes if only violated convexification cuts should be added ↩

Default: yes

Values: no, yes

warm_start (*string*): Select the warm start method ↩

This will affect the function getWarmStart(), and as a consequence the warm starting in the various algorithms.

Default: none

value	meaning
fake_basis	builds fake basis, useful for cut management in Cbc (warm start is the same as in none)
interior_point	Warm start with an interior point of direct parent
none	No warm start, just start NLPs from optimal solution of the root relaxation
optimum	Warm start with direct parent optimum

warm_start_bound_frac (*real*): same as bound_frac for the regular initializer. ↩

Range: [0, 0.5]

Default: 0.001

warm_start_bound_push (*real*): same as bound_push for the regular initializer. ↩

Default: 0.001

warm_start_init_point (*string*): Warm-start for initial point ↩

Indicates whether this optimization should use a warm start initialization, where values of primal and dual variables are given (e.g., from a previous optimization of a related problem.)

Default: no

value	meaning
no	do not use the warm start initialization
yes	use the warm start initialization

warm_start_mult_bound_push (*real*): same as mult_bound_push for the regular initializer. [↩](#)

Default: 0.001

warm_start_mult_init_max (*real*): Maximum initial value for the equality multipliers. [↩](#)

Range: $[-\infty, \infty]$

Default: 1e+06

warm_start_slack_bound_frac (*real*): same as slack_bound_frac for the regular initializer. [↩](#)

Range: $[0, 0.5]$

Default: 0.001

warm_start_slack_bound_push (*real*): same as slack_bound_push for the regular initializer. [↩](#)

Default: 0.001

watchdog_shortened_iter_trigger (*integer*): Number of shortened iterations that trigger the watchdog. [↩](#)

If the number of successive iterations in which the backtracking line search did not accept the first trial point exceeds this number, the watchdog procedure is activated. Choosing "0" here disables the watchdog procedure.

Default: 10

watchdog_trial_iter_max (*integer*): Maximum number of watchdog iterations. [↩](#)

This option determines the number of trial iterations allowed before the watchdog procedure is aborted and the algorithm returns to the stored point.

Range: $[1, \infty]$

Default: 3

5.15 CPLEX 12

5.15.1 Introduction

GAMS/Cplex is a GAMS solver that allows users to combine the high level modeling capabilities of GAMS with the power of Cplex optimizers. Cplex optimizers are designed to solve large, difficult problems quickly and with minimal user intervention. Access is provided (subject to proper licensing) to Cplex solution algorithms for linear, quadratically constrained and mixed integer programming problems. While numerous solving options are available, GAMS/Cplex automatically calculates and sets most options at the best values for specific problems.

All Cplex options available through GAMS/Cplex are summarized at the end of this document.

5.15.2 How to Run a Model with Cplex

The following statement can be used inside your GAMS program to specify using Cplex

```
Option LP = Cplex;      { or QCP, MIP, MIQCP, RMIP or RMIQCP }
```

The above statement should appear before the Solve statement. If Cplex was specified as the default solver during GAMS installation, the above statement is not necessary.

There are two Cplex links in the GAMS system: GAMS/Cplex and GAMS/CplexD. The CplexD solver link lack some functionality available in the Cplex link (e.g. sensitivity analysis for linear programs, support for SOS variables), but CplexD offers a few facility of interest to a small community:

- handles quadratically constraint models better than the production link. Some SOCP models are reformulated in the production link so that Cplex rejects these models while CplexD solves them nicely. Moreover, CplexD provides duals for this problem type.
- provides *hot start* capability in [Gather-Update-Solve-Scatter \(GUSS\)](#)
- allows solving multiple instances of `GAMSModelInstance` in parallel using the high-level GAMS APIs
- supports remote solves via the Cplex Remote Object
- supports Cplex' distributed MIP algorithm
- allows to free some additional memory via the option [FreeGamsModel](#) which is beneficial if memory is tight Unless you have need for these features it is recommended to use Cplex not CplexD. In the near future the two links will be merged.

Finally, a bare-bone interface to the LP and MIP solver of Cplex is available under the name [OSICPLEX](#). It comes free of charge with any GAMS system.

5.15.3 Overview of Cplex

5.15.3.1 Linear Programming

Cplex solves LP problems using several alternative algorithms. The majority of LP problems solve best using Cplex's state of the art dual simplex algorithm. Certain types of problems benefit from using the primal simplex algorithm, the network optimizer, the barrier algorithm, or the sifting algorithm. The concurrent option will allow solving with different algorithms in parallel. The solution is returned by the first to finish.

Solving linear programming problems is memory intensive. Even though Cplex manages memory very efficiently, insufficient physical memory is one of the most common problems when running large LPs. When memory is limited, Cplex will automatically make adjustments which may negatively impact performance. If you are working with large models, study the section entitled [Physical Memory Limitations](#) carefully.

Cplex is designed to solve the majority of LP problems using default option settings. These settings usually provide the best overall problem optimization speed and reliability. However, there are occasionally reasons for changing option settings to improve performance, avoid numerical difficulties, control optimization run duration, or control output options.

Some problems solve faster with the primal simplex algorithm rather than the default dual simplex algorithm. Very few problems exhibit poor numerical performance in both the primal and the dual. Therefore, consider trying primal simplex if numerical problems occur while using dual simplex.

Cplex has a very efficient algorithm for network models. Network constraints have the following property:

- each non-zero coefficient is either a +1 or a -1
- each column appearing in these constraints has > exactly 2 nonzero entries, one with a +1 > coefficient and one with a -1 coefficient

Cplex can also automatically extract networks that do not adhere to the above conventions as long as they can be transformed to have those properties.

The barrier algorithm is an alternative to the simplex method for solving linear programs. It employs a primal-dual logarithmic barrier algorithm which generates a sequence of strictly positive primal and dual solutions. Specifying the barrier algorithm may be advantageous for large, sparse problems.

Cplex provides a sifting algorithm which can be effective on problems with many more variables than equations. Sifting solves a sequence of LP subproblems where the results from one subproblem are used to select columns from the original model for inclusion in the next subproblem.

GAMS/Cplex also provides access to the Cplex Conflict Refiner previously known as IIS (Irreducibly Inconsistent Set). The conflict refiner takes an infeasible program and produces an set of conflicting constraints. Such a set consists of constraints and variable bounds which is infeasible but becomes feasible if any one member of the set is dropped. GAMS/Cplex reports the conflict in terms of GAMS equation and variable names and includes the conflict report as part of the normal solution listing.

5.15.3.2 Quadratically Constrained Programming

Cplex can solve models with quadratic constraints. These are formulated in GAMS as models of type QCP. QCP models are solved with the Cplex Barrier method.

QP models are a special case that can be reformulated to have a quadratic objective function and only linear constraints. Those are automatically reformulated from GAMS QCP models. When such problems are convex, Cplex normally solves them efficiently in polynomial time. Nonconvex QPs, however, are known to be quite hard. Cplex applies various approaches to those problems, such approaches as barrier algorithms or branch and bound algorithms. Notably, in the branch and bound approach, there is no theoretical guarantee about the complexity of such a problem. Consequently, solution of such a problem (that is, a nonconvex QP) can take many orders of magnitude longer than the solution of a convex QP of comparable dimensions. Therefore, the default is to reject such model. The parameter [OptimalityTarget](#) allows to change this behavior.

For QCP models Cplex returns a primal only solution to GAMS. CplexD provides in most cases also dual values.

5.15.3.3 Mixed-Integer Programming

The methods used to solve pure integer and mixed integer programming problems require dramatically more mathematical computation than those for similarly sized pure linear programs. Many relatively small integer programming models take enormous amounts of time to solve.

For problems with integer variables, Cplex uses a branch and cut algorithm which solves a series of LP, subproblems. Because a single mixed integer problem generates many subproblems, even small mixed integer problems can be very compute intensive and require significant amounts of physical memory.

GAMS and GAMS/Cplex support Special Order Sets of type 1 and type 2 as well as semi-continuous and semi-integer variables.

Cplex can also solve problems of GAMS model type MIQCP. As in the continuous case, if the base model is a QP the Simplex methods can be used and duals will be available at the solution. If the base model is a QCP, only the Barrier method can be used for the nodes and only primal values will be available at the solution.

5.15.3.4 Feasible Relaxation

The Conflict Refiner identifies the causes of infeasibility by means of inconsistent set of constraints. However, you may want to go beyond diagnosis to perform automatic correction of your model and then proceed with delivering a solution. One approach for doing so is to build your model with explicit slack variables and other modeling constructs, so that an infeasible outcome is never a possibility. An automated approach offered in GAMS/Cplex is known as FeasOpt (for Feasible Optimization) and turned on by parameter [FeasOpt](#) in a CPLEX option file. More details can be found in the section entitled [Using the Feasibility Relaxation](#).

5.15.3.5 Solution Pool: Generating and Keeping Multiple Solutions

This section introduces the *solution pool* for storing multiple solutions to a mixed integer programming problem (MIP and MIQCP). The chapter also explains techniques for generating and managing those solutions.

The solution pool stores multiple solutions to a mixed integer programming (MIP and MIQCP) model. With this feature, you can direct the algorithm to generate multiple solutions in addition to the optimal solution. For example, some constraints may be difficult to formulate efficiently as linear expressions, or the objective may be difficult to quantify exactly. In such cases, obtaining multiple solutions will help you choose one which best fits all your criteria, including the criteria that could not be expressed easily in a conventional MIP or MIQCP model. For example,

- You can collect solutions within a given percentage of the optimal solution. To do so, apply the solution pool gap parameters [SolnPoolAGap](#) and [SolnPoolGap](#).
- You can collect a set of diverse solutions. To do so, use the solution pool replacement parameter [SolnPoolReplace](#) to set the solution pool replacement strategy to 2. In order to control the diversity of solutions even more finely, apply a *diversity filter*.
- In an advanced application of this feature, you can collect solutions with specific properties. To do so, see the use of the *incumbent filter*.
- You can collect all solutions or all optimal solutions to model. To do so, set the solution pool intensity parameter [SolnPoolIntensity](#) to its highest value.

Please note, that the value for *best possible* can exceed the optimal solution value if CPLEX has already solved the model to optimality but continues to search for additional solutions.

5.15.3.5.1 Filling the Solution Pool There are two ways to fill the solution pool associated with a model: You can *accumulate* successive incumbents or generate alternative solutions by *populating* the solution pool. The method is selected with the parameter [SolnPoolPop](#):

- The regular optimization procedure automatically adds incumbents to the solution pool as they are discovered ([SolnPoolPop](#) = 1).
- Cplex also provides a procedure specifically to generate multiple solutions. You can invoke this procedure by setting option [SolnPoolPop](#) = 2. You can also invoke this procedure many times in a row in order to explore the solution space differently. In particular, you may invoke this procedure multiple times to find additional solutions, especially if the first solutions found are not satisfactory. This is done by specifying a GAMS program (option [SolnPoolPopRepeat](#)) that inspects the solutions. In case this GAMS program terminates normally, i.e. no execution or compilation error, the exploration for alternative solutions proceeds.

The option [SolnPoolReplace](#) designates the strategy for replacing a solution in the solution pool when the solution pool has reached its capacity. The value 0 replaces solutions according to a first-in, first-out policy. The value 1 keeps the solutions with the best objective values. The value 2 replaces solutions in order to build a set of diverse solutions.

If the solutions you obtain are too similar to each other, try setting [SolnPoolReplace](#) to 2.

The replacement strategy applies only to the subset of solutions created in the current call of `populate`. Solutions already in the pool are not affected by the replacement strategy. They will not be replaced, even if they satisfy the criterion of the replacement strategy. So with every repeated call of the `populate` procedure the solution pool will be extended by the newly found solution. After the GAMS program specified in [SolnPoolPopRepeat](#) determined to continue the search for alternative solutions, the file specified by option [SolnPoolPopDel](#) option is read in. The solution numbers present in this file will be delete from the solution pool before the `populate` routine is called again. The file is automatically deleted by the GAMS/Cplex link after processing.

5.15.3.5.2 Enumerating All Solutions With the solution pool, you can collect all solutions to a model. To do so, set the solution pool intensity parameter [SolnPoolIntensity](#) to its highest value, 4 and set [SolnPoolPop](#) = 2.

You can also enumerate all solutions that are valid for a specific criterion. For example, if you want to enumerate all alternative optimal solutions, do the following:

- Set the pool absolute gap parameter [SolnPoolAGap](#) = 0.0.
- Set the pool intensity parameter [SolnPoolIntensity](#) = 4.
- Set the populate limit parameter [PopulateLim](#) to a value sufficiently large for your model; for example, 2100000000.
- Set the pool population parameter [SolnPoolPop](#) = 2.

Beware, however, that, even for small models, the number of possible solutions is likely to be huge. Consequently, enumerating all of them will take time and consume a large quantity of memory.

There may be an infinite number of possible values for a continuous variable, and it is not practical to enumerate all of them on a finite-precision computer. Therefore, `populate` gives only one solution for each set of binary and integer variables, even though there may exist several solutions that have the same values for all binary and integer variables but different values for continuous variables.

Likewise, for the same reason, the `populate` procedure does not generate all possible solutions for unbounded models. As soon as the proof of unboundedness is obtained, the `populate` procedure stops.

Cplex uses numerical methods of finite-precision arithmetic. Consequently, the feasibility of a solution depends on the value given to tolerances. Two parameters define the tolerances that assess the feasibility of a solution:

- the integrality tolerance [EpInt](#)
- the feasibility tolerance [EpRHS](#)

A solution may be considered feasible for one pair of values for these two parameters, and infeasible for a different pair. This phenomenon is especially noticeable in models with numeric difficulties, for example, in models with BigM coefficients.

Since the definition of a feasible solution is subject to tolerances, the total number of solutions to a model may vary, depending on the approach used to enumerate solutions, and on precisely which tolerances are used. In most models, this tolerance issue is not problematic. But, in the presence of numeric difficulties, Cplex may create solutions that are slightly infeasible or integer infeasible, and therefore create more solutions than expected.

5.15.3.5.3 Filtering the Solution Pool Filtering allows you to control properties of the solutions generated and stored in the solution pool. Cplex provides two predefined ways to filter solutions.

If you want to filter solutions based on their difference as compared to a reference solution, use a *diversity filter*. This filter is practical for most purposes. However, if you require finer control of which solutions to keep and which to eliminate, use the *incumbent filter*.

5.15.3.5.4 Diversity Filter A diversity filter allows you to generate solutions that are similar to (or different from) a set of reference values that you specify for a set of binary variables using [dot option DivFlt](#) and lower and upper bounds [DivFltLo](#) and [DivFltUp](#). In particular, you can use a diversity filter to generate more solutions that are similar to an existing solution or to an existing partial solution. If you need more than one diversity filter, for example, to generate solutions that share the characteristics of several different solutions, additional filters can be specified through a Cplex Filter File using parameter [ReadFLT](#). Details can be found in the example model `solnpool` in the GAMS model library.

5.15.3.5.5 Incumbent Filter If you need to enforce more complex constraints on solutions (e.g. if you need to enforce nonlinear constraints), you can use the incumbent filtering. The incumbent checking routine is part of the [GAMS BCH Facility](#). It will accept or reject incumbents independent of a solution pool. During the populate or regular optimize procedure, the incumbent checking routine specified by the parameter [UserIncbCall](#) is called each time a new solution is found, even if the new solution does not improve the objective value of the incumbent. The incumbent filter allows your application to accept or reject the new solution based on your own criteria. If the GAMS program specified by [UserIncbCall](#) terminates normally, the solution is rejected. If this program returns with a compilation or execution error, the incumbent is accepted.

5.15.3.5.6 Accessing the Solution Pool The solutions are stored in [GAMS Data eXchange](#) (GDX) file and can be loaded by your GAMS program. Details can be found in the model `solnpool` in the GAMS model library and in [. .](#) If you instruct Cplex to generate thousands of solution this becomes inefficient. The option [SolnPoolMerge](#) triggers the creation of a single GDX file containing all solutions.

The GAMS/Cplex link produces, if properly instructed, a [GAMS Data eXchange\(GDX\)](#) file with name specified in [SolnPool](#) that contains a set `Index` with elements `file1`, `file2`, ... The associated text of these elements contain the file names of the individual GDX solution file. The name is constructed using the prefix `soln` (which can be specified differently by option [SolnPoolPrefix](#)), the name of the model and a sequence number. For example `soln_loc_p1.gdx`. GAMS/Cplex will overwrite existing GDX files without warning. The set `Index` allows us to conveniently walk through the different solutions in the solution pool. A complete model can be found in the model `solnpool` in the GAMS model library.

```
...
solve mymodel min z using mip;

set soln           possible solutions in the solution pool /file1*file1000/
    solnpool(soln) actual solutions;
file fsol;

execute_load 'solnpool.gdx', solnpool=Index;
loop(solnpool(soln),
    put_utility fsol 'gdxin' / solnpool.te(soln):0:0;
    execute_loadpoint;
    display z.1;
);
```

If you instruct Cplex to generate thousands of solution this method becomes inefficient. The option [SolnPoolMerge](#) triggers the creation of a single GDX file containing all solutions. Details on usage of this option can be found in the model `solmpool` in the GAMS model library.

5.15.3.6 Cplex Remote Object Server and Distributed MIP

The Cplex Remote Object Server allows you to use a server to offload all of your Cplex computations.

Cplex Remote Object Server licenses and software are not included in GAMS/Cplex. Contact support@gams.com to inquire about the software and license. You can specify the server with the [ComputeServer](#) option.

Cplex also supports solving a single MIP instance utilizing multiple machines in a distributed fashion. The feature is known as *Distributed MIP* and builds on top of the Cplex Remote Object Server. This section describes the setup steps necessary to enable this feature. First there is some background information about CPLEX Distributed MIP.

5.15.3.6.1 Solving a distributed MIP in parallel CPLEX offers more support for the solution in parallel of mixed integer programs (MIPs) in a distributed computing environment. This feature, known as distributed parallel MIP optimization, is a mode of running CPLEX that harnesses the power of multiple computers or of multiple nodes inside a single computer to achieve better performance on some MIP problems.

Distributed parallel MIP optimization operates in two phases: first, a *ramp-up phase*, in which each worker applies different parameter settings to the same problem as the other workers; then, in the remainder of the solve (the second phase), each worker works in one part of a common MIP tree. Each worker communicates what it finds to the (unique) master node, which acts as the conductor or coordinator for the whole process.

Distributed MIP is based on the CPLEX remote object for distributed parallel optimization.

Distributed parallel mixed integer programming uses a variation of the well known branch and bound algorithm to solve a MIP in parallel. In contrast to conventional branch and bound implemented on platforms with shared memory, distributed parallel MIP implements a branch and bound algorithm in an environment of distributed memory, possibly across multiple machines. The implementation can use more than a single machine to solve a given MIP, thus making it possible to solve more difficult problems than a shared memory on a single machine could solve.

5.15.3.6.2 Distributed optimization of MIPs: The Algorithm This topic outlines an algorithm that implements a variation of branch and bound suitable for application across multiple machines (or multiple nodes of a single machine) to solve a difficult mixed integer program (MIP) in parallel.

This distributed parallel MIP algorithm runs on a single master associated with multiple workers. The master and the workers can be physical or virtual machines. Indeed, in this context, a virtual machine may simply be a process in the operating system of a machine. Throughout the runtime of this algorithm, the master coordinates the workers, and the workers perform the *heavy lifting* (that is, the actual solving of the MIP).

The algorithm begins by presolving the MIP on the master. After presolving, the algorithm sends the reduced model to each of the workers.

Each of the workers then starts to solve the reduced model. Each worker has its own parameter settings, possibly different from the parameter settings of other workers. Each worker solves the reduced model with its own parameter settings for a limited period of time. This phase is known as ramp up. During ramp up, each worker conducts its own search, according to its own parameter settings. Ramp up stops when the master concludes that at least one of the workers has created a sufficiently large search tree.

At that point, when ramp up stops, the master decides which of the workers performed best. In other words, the master selects a winner. The parameter settings used by the winning worker during ramp up are the basis for the master to determine which parameter settings to use in the ensuing distributed branch and bound search.

The search tree on each of the non-winning workers is deleted. The search tree of the winning worker is distributed over all workers, so that authentic distributed parallel branch and bound starts from this point. In other words, all workers now work on the same search tree, with the master coordinating the search in the distributed tree.

5.15.3.6.3 Search tree Distributed parallel branch and bound is similar to conventional, shared-memory branch and bound. They differ greatly, however, in their management of the search tree. In a conventional, shared-memory branch and bound, the search tree resides on a single machine, on disk or in shared memory. In contrast, distributed parallel branch and bound literally distributes the search tree across a cluster of machines.

In the CPLEX implementation of distributed parallel branch and bound, the master keeps a number of nodes of the global search tree. If a worker becomes idle, the master sends some of those nodes to that worker. The worker then starts branch and bound on those nodes. However, the worker does not simply solve a node, create some new nodes in doing so, and send them all back to the master. Instead, the worker considers the search tree node received from the master as a new MIP. The worker presolves that MIP and finds an optimal solution for that node using branch and bound. In other words, a worker not only solves a single node; in fact, the worker solves an entire subtree rooted at that node.

While this distributed parallel branch and bound algorithm is running, the master can ask a worker to provide some open nodes (that is, unsolved nodes). The master can then use these nodes to assign work to idle workers. To satisfy such a request from the master, a worker picks a few open nodes from its current tree. Because the current tree in a worker is a subtree of the global tree (indeed, it is the subtree rooted at the node sent to the worker), every node in that subtree is also a node in the global tree.

5.15.3.6.4 Stopping criterion The distributed parallel branch and bound algorithm stops if all the nodes of the global search tree have been processed or if it reaches a limit set by the user. Such limits include a time limit, a limit on the number of nodes processed, a limit on the number of solutions found, or other similar criteria.

5.15.3.6.5 Using TCP/IP as the transport protocol with distributed parallel MIP While Cplex has multiple transport protocols (e.g. MPI) GAMS/CPLEXD uses exclusively the TCP/IP transport protocol. In order to use the distributed MIP facility you need the additional software package from GAMS (contact support@gams.com). Moreover you need a set of machines that act as workers. Upload the software (provided as a ZIP archive) to these machines. On each work machine create a directory and unzip the ZIP file in this directory:

```
mkdir c:\tmp\gamscplexdistmip
cd c:\tmp\gamscplexdistmip
unzip from\some\where\windows_x86_32_cpxdistmip.zip
```

Find out the worker IP address, e.g. via ipconfig (on Windows based systems) and start the Cplex worker process:

```
cplex -worker=tcip -libpath=c:\tmp\gamscplexdistmip -address=myip:myport
```

where **myip** is the name of the host or its IP address and **myport** is the number of the port where the worker will listen for incoming connections. (You are free to choose a different port number here.

This command starts a TCP/IP server to wait for connections from the master. The TCP/IP server also spawns worker processes as requested. The server does not terminate itself, however. You must explicitly terminate it; for example, by pressing CTRL-C when your optimization completes.

On the master machine with a regular GAMS installation create a **cplexd.opt** file with the following content specifying the IP addresses or names and ports of the workers:

```
computeserver myip1:myport1 myip2:myport2 ...
```

The host names and the port numbers must be the same in the CplexD option file as those used to start the TCP/IP worker on the corresponding host. Please note, that when you specify a single machine, one gets the Cplex Remote Object solving sequentially on a remote machine instead of a distributed MIP run.

Run GAMS solving a mixed integer model with CplexD and the option reading enabled.

The log of such a run will look as follows (please observe the mentioning of **Starting ramp-up**)

```

5.15.3.6.6 Parameters for Distributed MIP There are a few parameters that effect the distributed MIP. The following parameters (only applicable in CplexD) enable you to customize this ramp-up phase for your model.

- To set the duration of the ramp-up phase, use the ramp up duration parameter, [RampupDuration](#).
- To set a deterministic time limit on the ramp-up phase, use the deterministic time spent in ramp up during distributed parallel optimization parameter, [RampupDetTimeLimit](#)
- To set a wall-clock time limit in seconds on the ramp-up phase, use the time spent in ramp up during distributed parallel optimization parameter, [RampupTimeLimit](#).

5.15.3.7 Benders Algorithm

CPLEX implements Benders algorithm.

Given a formulation of a problem, CPLEX can decompose the model into a single master and (possibly multiple) subproblems. To do so, CPLEX makes use of annotations that you supply for your model. This approach can be applied to mixed-integer linear programs (MILP). For certain types of problems, this approach can offer significant performance improvements.

The parameter, [BendersStrategy](#), specifies to CPLEX how you want to apply Benders algorithm as a strategy to solve your model. By default, if you did not annotate your model to specify a decomposition, CPLEX executes conventional branch and bound. If you annotated your model, CPLEX attempts to refine your decomposition and applies Benders algorithm. With this parameter, you can direct CPLEX to decompose your model and to apply its implementation of Benders algorithm in one of these alternative ways:

- 1: CPLEX attempts to decompose your model strictly according to your annotations.
- 2: CPLEX decomposes your model by using your annotations as hints and refining the decomposition where it can. CPLEX initially decomposes your model according to your annotation and then attempts to refine that decomposition by further decomposing the specified subproblems. This approach can be useful if you annotate certain variables to go into master, and all others to go into a single subproblem, which CPLEX can then decompose further for you.
- 3: CPLEX automatically decomposes your model, ignoring any annotations you may have supplied. CPLEX puts all integer variables into the master, puts all continuous variables into a subproblem and decomposes that subproblem, if possible.

If you want to specify a decomposition to CPLEX, you need to annotate your model and specify a Benders partition of your variable space. These Benders partition can be conveniently specified with the [dot option BendersPartition](#) or through the [.stage variable suffix](#).

These Benders partition values specify to CPLEX whether certain variables belong to the master or to one of the subproblems assigned to workers (where the subproblems are numbered from 1 (one) to N, the number of subproblems). If you annotate a given variable with the value 0 (zero), CPLEX assigns that variable to the master. If you annotate a given variable with the value *i*, where *i* is greater than or equal to 1 (one), CPLEX assigns that variable to subproblem *i*. If a variable is not specified, the default will be to go into the master problem. Note that with `variable.BendersPartition 1` you can assign all variables to the subproblem and then selectively assign the master variables with `varname.BendersPartition 0`.

If you want to communicate the Benders partition values via the [.stage variable suffix](#), the partition numbers are off by one compared to the partition number via the dot option. So the master variables have stage 1, and the subproblems start with stage 2. If you want to leave a variable unassigned you can either make the stage 0 or fractional (e.g. 1.5). Discrete variables are automatically put into the master problem and don't need to be set (actually the [.stage suffix](#) is even not available for discrete variables). In addition to specifying the Benders partition values via the [.stage variable suffix](#) the link option [BendersPartitionInStage](#) needs to be set to 1.

CPLEX produces an error if the annotated decomposition does not yield disjoint subproblems. For example, if your annotations specify that two (or more) variables belong in different subproblems, yet your model specifies that these variables participate in the same constraint, then these variables are linked. Consequently, the subproblems where these variables appear according to your annotations are not disjoint with respect to the partition.

5.15.3.8 Multiple Objectives

While typical optimization models have a single objective function, real-world optimization problems often have multiple, competing objectives. For example, in a production planning model, you may want to both maximize profits and minimize late orders, or in a workforce scheduling application, you may want to both minimize the number of shifts that are short-staffed while also respecting worker's shift preferences.

The main challenge you face when working with multiple, competing objectives is deciding how to manage the tradeoffs between them. Cplex provides tools that simplify the task: Cplex allows you to blend multiple objectives, to treat them *hierarchically*, or to combine the two approaches. In a blended approach, you optimize a weighted combination of the individual objectives. In a hierarchical or *lexicographic* approach, you set a priority for each objective, and optimize in priority order. When optimizing for one objective, you only consider solutions that would not degrade the objective values of higher-priority objectives. Cplex allows you to enter and manage your objectives, to provide weights for a blended approach, or to set priorities for a hierarchical approach. Cplex will only solve multi-objective models with strictly linear objectives. Moreover, for continuous models, Cplex will report a primal only solution (not dual information).

Following the workforce application the specifications of the objectives would be done as follows:

```

equations defObj, defNumShifts, defSumPreferences;
variables obj, numShifts, sumPreferences;

defobj..          obj =e= numShifts - 1/100*sumPreferences;
defNumShifts..    numShifts =e= ...;
defSumPreferences.. sumPreferences =e= ...;

model workforce /all/;
solve workforce minimizing obj using mip;

```

With the default setting Cplex will solve the blended objective. Using the parameter [MultObj](#) Cplex will use a hierarchical approach. A hierarchical or lexicographic approach assigns a priority to each objective, and optimizes for the objectives in decreasing priority order. At each step, it finds the best solution for the current objective, but only from among those that would not degrade the solution quality for higher-priority objectives. The priority is specified by the absolute value of the objective coefficient in the blended objective function (`defObj`). In the example, the `numShifts` objective with coefficient 1 has higher priority than the `sumPreferences` objective with absolute objective coefficient 1/100. The sign of the objective coefficient determines the direction of the particular objective function. So here `numShifts` will be minimized (same direction as on the `solve` statement) while `sumPreferences` will be maximized. GAMS needs to identify the various objective functions, therefore the objective variables can only appear in the blended objective functions and in the particular objective defining equation.

By default, the hierarchical approach won't allow later objectives to degrade earlier objectives. This behavior can be relaxed through a pair of attributes: [ObjNRelTol](#) and [ObjNAbsTol](#). By setting one of these for a particular objective, you can indicate that later objectives are allowed to degrade this objective by the specified relative or absolute amount, respectively. In our earlier example, if the optimal value for `numShifts` is 100, and if we set [ObjNAbsTol](#) for this objective to 20, then the second optimization step maximizing `sumPreferences` would find the best solution for the second objective from among all solutions with objective 120 or better for `numShifts`. Note that if you modify both tolerances, later optimizations would use the looser of the two values (i.e., the one that allows the larger degradation).

5.15.4 GAMS Options

The following GAMS options are used by GAMS/Cplex:

- **Option BRatio = x;**

Determines whether or not to use an advanced basis. A value of 1.0 causes GAMS to instruct Cplex not to use an advanced basis. A value of 0.0 causes GAMS to construct a basis from whatever information is available. The default value of 0.25 will nearly always cause GAMS to pass along an advanced basis if a solve statement has previously been executed.

- **Option IterLim = n;**

Sets the simplex iteration limit. Simplex algorithms will terminate and pass on the current solution to GAMS.

Cplex handles the iteration limit for MIP problems differently than some other GAMS solvers. The iteration limit is applied per node instead of as a total over all nodes. For MIP problems, controlling the length of the solution run by limiting the execution time (`ResLim`) is preferable.

Similarly, when using the sifting algorithm, the iteration limit is applied per sifting iteration (ie per LP). The number of sifting iterations (LPs) can be limited by setting Cplex parameter [SiftItLim](#). It is the number of sifting iterations that is reported back to GAMS as iterations used.

- **Option ResLim = x;**

Sets the time limit in seconds. The algorithm will terminate and pass on the current solution to GAMS.

- **Option SysOut = On;**

Will echo Cplex messages to the GAMS listing file. This option may be useful in case of a solver failure.

- **ModelName.Cheat = x;**

Cheat value: each new integer solution must be at least x better than the previous one. Can speed up the search, but you may miss the optimal solution. The cheat parameter is specified in absolute terms (like the OptCA option). The Cplex option [ObjDif](#) overrides the GAMS cheat parameter.

- **ModelName.Cutoff = x;**

Cutoff value. When the branch and bound search starts, the parts of the tree with an objective worse than x are deleted. This can sometimes speed up the initial phase of the branch and bound algorithm.

- **ModelName.NodLim = x;**

Maximum number of nodes to process for a MIP problem.

Option OptCA = x;

Absolute optimality criterion for a MIP problem. The OptCA option asks Cplex to stop when

$$|BP - BF| < \text{OptCA}$$

where *BF* is the objective function value of the current best integer solution while *BP* is the best possible integer solution.

- **ModelName.OptCR = x;**

Relative optimality criterion for a MIP problem. Notice that Cplex uses a different definition than GAMS normally uses. The OptCR option asks Cplex to stop when

$$(|BP - BF|)/(1.0e - 10 + |BF|) < \text{OptCR}$$

where *BF* is the objective function value of the current best integer solution while *BP* is the best possible integer solution. The GAMS definition is:

$$(|BP - BF|)/(|BP|) < \text{OptCR}$$

- **ModelName.OptFile= 1;**

Instructs Cplex to read the option file. The name of the option file is `cplex.opt`.

- **ModelName.PriorOpt= 1;**

Instructs Cplex to use priority branching information passed by GAMS through the `variable.prior` parameters.

- **ModelName.TryInt= x;**

Causes GAMS/Cplex to make use of current variable values when solving a MIP problem. If a variable value is within x of a bound, it will be moved to the bound and the preferred branching direction for that variable will be set toward the bound. The preferred branching direction will only be effective when priorities are used. Priorities and tryint are sometimes not very effective and often outperformed by GAMS/CPLEX default settings. Supporting GAMS/CPLEX with knowledge about a known solution can be passed on by different means, please read more about this in section entitled [Starting from a MIP Solution](#).

GAMS/Cplex also sets many model attributes that can be used in your GAMS program by accessing *ModelName.suffix*. A list of model attributes available after the solve can be found here [Model Attributes Mainly Used After Solve](#).

Cplex has the concept of deterministic time i.e. a measure of time that respects the same solution path to arrive at the same values in the solution while it yields the same level of performance for repeated solving of the same model with the same parameter settings, on the same computing platform. The length of a deterministic time tick may vary by platform. Nevertheless, ticks are normally consistent measures for a given platform (combination of hardware and software) carrying the same load. In other words, the correspondence of ticks to clock time depends on the hardware, software, and the current load of the machine. For the same platform and same load, the ratio of ticks per second stays roughly constant, independent of the model solved. However, for very short optimization runs, the variation of this ratio is typically high. GAMS/Cplex reports the deterministic time ticks spend inside Cplex in the model attribute `ETA1g`. Normally `ETA1g` is reporting the seconds.

5.15.5 Summary of CPLEX Options

The various Cplex options are listed here by category, with a few words about each to indicate its function. The options are listed again, in alphabetical order and with detailed descriptions, in the last section of this document.

5.15.5.1 Preprocessing and General Options

Option	Description	Default
advind	advanced basis use	determined by GAMS <code>Bratio</code>
aggfill	aggregator fill parameter	10
aggind	aggregator on/off	-1
calcqcpduals	calculate the dual values of a quadratically constrained problem	1
clocktype	clock type for computation time	2
coeredind	coefficient reduction on/off	-1
computeserver	address and port of Cplex remote object server	
cpumask	switch and mask to bind threads to processors	auto
datacheck	controls data consistency checking and modeling assistance	0
depind	dependency checker on/off	-1
dettilim	deterministic time limit	1e+075
feasopt	computes a minimum-cost relaxation to make an infeasible model feasible	0
feasoptmode	mode of FeasOpt	0
.feaspref	feasibility preference	1
folding	LP folding will be attempted during the preprocessing phase	-1
freegamsmodel	preserves memory by dumping the GAMS model instance representation temporarily to disk	0

Option	Description	Default
interactive	allow interactive option setting after a Control-C	0
lpmethod	algorithm to be used for LP problems	0
memoryemphasis	reduces use of memory	0
multobj	controls the hierarchical optimization of multiple objectives	0
multobjdisplay	level of display during multiobjective optimization	1
multobjmethod	method used for multi-objective solves	0
names	load GAMS names into Cplex	1
numeralemphasis	emphasizes precision in numerically unstable or difficult problems	0
objnabstol	allowable absolute degradation for objective	
objnreltol	allowable relative degradation for objective	
objrng	do objective ranging	no objective ranging is done
optimalitytarget	type of optimality that Cplex targets	0
parallelmode	parallel optimization mode	1
predual	give dual problem to the optimizer	0
preind	turn presolver on/off	1
prelinear	linear reduction indicator	1
prepass	number of presolve applications to perform	-1
printoptions	list values of all options to GAMS listing file	0
qpmethod	algorithm to be used for QP problems	0
qtolin	linearization of the quadratic terms in the objective function of a QP or MIQP model	-1
reduce	primal and dual reduction type	3
relaxpreind	presolve for initial relaxation on/off	-1
rerun	rerun problem if presolve infeasible or unbounded	yes
rhsrng	do right-hand-side ranging	no right-hand-side ranging is done
rngrestart	write GAMS readable ranging information file	ranging information is printed to the listing file
scaind	matrix scaling on/off	0
solutiontype	type of solution (basic or non basic) for an LP or QP	0
threads	global default thread count	GAMS Threads
tilim	overrides the GAMS ResLim option	GAMS ResLim

Option	Description	Default
tuning	invokes parameter tuning tool	
tuningdettlim	tuning deterministic time limit per model or suite	1e+007
tuningdisplay	level of information reported by the tuning tool	1
tuningmeasure	measure for evaluating progress for a suite of models	1
tuningrepeat	number of times tuning is to be repeated on perturbed versions	1
tuningtilim	tuning time limit per model or suite	0.2*GAMS ResLim
warninglimit	determines how many times warnings of a specific type (datacheck=2) will be displayed	10
workdir	directory for working files	current or project directory
workmem	memory available for working storage	128

5.15.5.2 Simplex Algorithmic Options

Option	Description	Default
craind	crash strategy (used to obtain starting basis)	1
dpriind	dual simplex pricing	0
dynamicrows	switch for dynamic management of rows	-1
epper	perturbation constant	1e-006
iis	run the conflict refiner also known as IIS finder if the problem is infeasible	0
netfind	attempt network extraction	2
netppriind	network simplex pricing	0
perind	force initial perturbation	0
perlim	number of stalled iterations before perturbation	0
ppriind	primal simplex pricing	0
pricelim	pricing candidate list	0, in which case it is determined automatically
reinv	refactorization frequency	0, in which case it is determined automatically
sifting	switch for sifting from simplex optimization	1

5.15.5.3 Simplex Limit Options

Option	Description	Default
itlim	iteration limit	GAMS IterLim

Option	Description	Default
netitlim	iteration limit for network simplex	large
objllim	objective function lower limit	-1e+075
objulim	objective function upper limit	1e+075
singlim	limit on singularity repairs	10

5.15.5.4 Simplex Tolerance Options

Option	Description	Default
epmrk	Markowitz pivot tolerance	0.01
epopt	optimality tolerance	1e-006
eprhs	feasibility tolerance	1e-006
netepopt	optimality tolerance for the network simplex method	1e-006
neteprhs	feasibility tolerance for the network simplex method	1e-006

5.15.5.5 Barrier Specific Options

Option	Description	Default
baralg	algorithm selection	0
barcolnz	dense column handling	0
barcrossalg	barrier crossover method	0
barepcomp	convergence tolerance	1e-008
bargrowth	unbounded face detection	1e+012
baritlim	iteration limit	large
barmaxcor	maximum correction limit	-1
barobjrng	maximum objective function	1e+020
barorder	row ordering algorithm selection	0
barqcpepcomp	convergence tolerance for the barrier optimizer for QCPs	1e-007
barstartalg	barrier starting point algorithm	1

5.15.5.6 Sifting Specific Options

Option	Description	Default
sifalg	sifting subproblem algorithm	0
siftitlim	limit on sifting iterations	large

5.15.5.7 MIP Algorithmic Options

Option	Description	Default
bbinterval	best bound interval	7
.benderspartition	Benders partition	0
benderspartitioninstage	Benders partition through stage variable suffix	0
bendersstrategy	Benders decomposition algorithm as a strategy	0
bndstrenind	bound strengthening	-1
bqpcuts	boolean quadric polytope cuts for nonconvex QP or MIQP solved to global optimality	0
brdir	set branching direction	0
bttol	backtracking limit	0.9999
cliques	clique cut generation	0
covers	cover cut generation	0
cutlo	lower cutoff for tree search	-1e+075
cuts	default cut generation	0
cutsfactor	cut limit	-1
cutup	upper cutoff for tree search	1e+075
disjcuts	disjunctive cuts generation	0
divetype	MIP dive strategy	0
eachcutlim	sets a limit for each type of cut	2100000000
flowcovers	flow cover cut generation	0
flowpaths	flow path cut generation	0
fpheur	feasibility pump heuristic	0
fraccuts	Gomory fractional cut generation	0
gubcovers	GUB cover cut generation	0
heurfreq	heuristic frequency	0
implbd	implied bound cut generation	0
lbheur	local branching heuristic	0
liftprojcuts	lift-and-project cuts	0
localimplied	generation of locally valid implied bound cuts	0
mcfcuts	multi-commodity flow cut generation	0
mipemphasis	MIP solution tactics	0
mipkappastats	MIP kappa computation	-1
mipordind	priority list on/off	GAMS PriorOpt
mipordtype	priority order generation	0

Option	Description	Default
mipsearch	search strategy for mixed integer programs	0
mipstart	use mip starting values	0
miqcpstrat	MIQCP relaxation choice	0
mircuts	mixed integer rounding cut generation	0
nodefileind	node storage file indicator	1
nodesel	node selection strategy	1
preslvnd	node presolve selector	0
probe	perform probing before solving a MIP	0
qpmakepsdind	adjust MIQP formulation to make the quadratic matrix positive-semi-definite	1
relaxfixedinfeas	accept small infeasibilities in the solve of the fixed problem	0
repeatpresolve	reapply presolve at root after preprocessing	-1
rinsheur	relaxation induced neighborhood search frequency	0
rtlcuts	Reformulation Linearization Technique (RLT) cuts	0
solvefinal	switch to solve the problem with fixed discrete variables	1
startalg	MIP starting algorithm	0
strongcandlim	size of the candidates list for strong branching	10
strongitlim	limit on iterations per branch for strong branching	0
subalg	algorithm for subproblems	0
submipodelim	limit on number of nodes in an RINS subMIP	500
submipscale	scale the problem matrix when CPLEX solves a subMIP during MIP optimization	0
submipstartalg	starting algorithm for a subMIP of a MIP	0
submipsubalg	algorithm for subproblems of a subMIP of a MIP	0
symmetry	symmetry breaking cuts	-1
varsel	variable selection strategy at each node	0
workeralgorithm	set method for optimizing benders subproblems	0
zerohalfcuts	zero-half cuts	0

5.15.5.8 MIP Limit Options

Option	Description	Default
aggcutlim	aggregation limit for cut generation	3
auxrootthreads	number of threads for auxiliary tasks at the root node	0
cutpass	maximum number of cutting plane passes	0

Option	Description	Default
fraccand	candidate limit for generating Gomory fractional cuts	200
fracpass	maximum number of passes for generating Gomory fractional cuts	0
intsollim	maximum number of integer solutions	large
nodelim	maximum number of nodes to solve	GAMS NodLim
polishafterdetime	deterministic time before starting to polish a feasible solution	1e+075
polishafterepagap	absolute MIP gap before starting to polish a feasible solution	0
polishafterepgap	relative MIP gap before starting to polish a solution	0
polishafterintsol	MIP integer solutions to find before starting to polish a feasible solution	2100000000
polishafternode	nodes to process before starting to polish a feasible solution	2100000000
polishaftertime	time before starting to polish a feasible solution	1e+075
probedetime	deterministic time spent probing	1e+075
probetime	time spent probing	1e+075
rampupdettimelimit	limits the amount of time in deterministic ticks spent during ramp up of distributed parallel optimization	1e+075
rampupduration	customizes ramp up for distributed parallel optimization	0
rampuptimelimit	limits the amount of time in seconds spent during ramp up of distributed parallel optimization	1e+075
repairtries	try to repair infeasible MIP start	0
trelim	maximum space in memory for tree	1e+075

5.15.5.9 MIP Solution Pool Options

Option	Description	Default
.divfft	solution pool range filter coefficients	0
divftlo	lower bound on diversity	mindouble
divftup	upper bound on diversity	maxdouble
populatelim	limit of solutions generated for the solution pool by populate method	20
randomseed	sets the random seed differently for diversity of solutions	changes with each Cplex release
readfft	reads Cplex solution pool filter file	
solnpool	solution pool file name	
solnpoolagap	absolute tolerance for the solutions in the solution pool	1e+075
solnpoolcapacity	limits of solutions kept in the solution pool	2100000000
solnpoolgap	relative tolerance for the solutions in the solution pool	1e+075

Option	Description	Default
solnpoolintensity	solution pool intensity for ability to produce multiple solutions	0
solnpoolmerge	solution pool file name for merged solutions	
solnpoolnumsym	maximum number of variable symbols when writing merged solutions	10
solnpoolpop	methods to populate the solution pool	1
solnpoolpopdel	file with solution numbers to delete from the solution pool	
solnpoolpoprepeat	method to decide if populating the solution should be repeated	
solnpoolprefix	file name prefix for GDX solution files	soln
solnpoolreplace	strategy for replacing a solution in the solution pool	0

5.15.5.10 MIP Tolerance Options

Option	Description	Default
bendersfeascuttol	Tolerance for whether a feasibility cut has been violated in Benders decomposition	1e-006
bendersoptcuttol	Tolerance for optimality cuts in Benders decomposition	1e-006
epagap	absolute stopping tolerance	GAMS OptCA
epgap	relative stopping tolerance	GAMS OptCR
epint	integrality tolerance	1e-005
objdif	overrides GAMS Cheat parameter	0
relobjdif	relative cheat parameter	0

5.15.5.11 Output Options

Option	Description	Default
bardisplay	progress display level	1
clonelog	enable clone logs	0
mipdisplay	progress display level	4
mipinterval	progress display interval	0
miptrace	filename of MIP trace file	
miptracenode	node interval when a trace record is written	100
miptracetime	time interval when a trace record is written	1
mpslongnum	MPS file format precision of numeric output	1
netdisplay	network display level	2

Option	Description	Default
quality	write solution quality statistics	0
siftdisplay	sifting display level	1
simdisplay	simplex display level	1
writeannotation	produce a Cplex annotation file	
writebas	produce a Cplex basis file	
writeflt	produce a Cplex solution pool filter file	
writelp	produce a Cplex LP file	
writemps	produce a Cplex MPS file	
writemst	produce a Cplex mst file	
writeord	produce a Cplex ord file	
writeparam	produce a Cplex parameter file with all active options	
writepre	produce a Cplex LP/MPS/SAV file of the presolved problem	
writeprob	produce a Cplex problem file and infers the type from the extension	
writesav	produce a Cplex binary problem file	

5.15.5.12 BCH Facility Options

Option	Description	Default
usercutcall	the GAMS command line to call the cut generator	
usercutfirst	calls the cut generator for the first n nodes	10
usercutfreq	determines the frequency of the cut generator model calls	10
usercutinterval	determines the interval when to apply the multiplier for the frequency of the cut generator model calls	100
usercutmult	determines the multiplier for the frequency of the cut generator model calls	2
usercutnewint	calls the cut generator if the solver found a new integer feasible solution	1
usergdxin	the name of the GDX file read back into Cplex	bchin.gdx
usergdxname	the name of the GDX file exported from the solver with the solution at the node	bchout.gdx
usergdxnameinc	the name of the GDX file exported from the solver with the incumbent solution	bchout.i.gdx
usergdxprefix	prefixes usergdxin, usergdxname, and usergdxnameinc	
usergdxsol	the name of the GDX file exported by Cplex to store the solution of extra columns	bchsol.gdx
userheurcall	the GAMS command line to call the heuristic	
userheurfirst	calls the heuristic for the first n nodes	10
userheurfreq	determines the frequency of the heuristic model calls	10
userheurinterval	determines the interval when to apply the multiplier for the frequency of the heuristic model calls	100

Option	Description	Default
userheurmalt	determines the multiplier for the frequency of the heuristic model calls	2
userheurnewint	calls the heuristic if the solver found a new integer feasible solution	1
userheurobjfirst	Similar to UserHeurFirst but only calls the heuristic if the relaxed objective promises an improvement	0
userincbcall	the GAMS command line to call the incumbent checking program	
userincbicall	the GAMS command line to call the incumbent reporting program	
userjobid	postfixes lf, o on call adds –userjobid to the call. Postfixes.gdxname, gdxnameinc and gdxin	
userkeep	calls gamskeep instead of gams	0

5.15.5.13 The GAMS/Cplex Options File

The GAMS/Cplex options file consists of one option or comment per line. An asterisk (*) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by any amount of white space (blanks or tabs).

Following is an example options file `cplex.opt`.

```
scaind 1
simdisplay 2
```

It will cause Cplex to use a more aggressive scaling method than the default. The iteration log will have an entry for each iteration instead of an entry for each refactorization.

5.15.6 Special Notes

5.15.6.1 Physical Memory Limitations

For the sake of computational speed, Cplex should use only available physical memory rather than virtual or paged memory. When Cplex recognizes that a limited amount of memory is available it automatically makes algorithmic adjustments to compensate. These adjustments almost always reduce optimization speed. Learning to recognize when these automatic adjustments occur can help to determine when additional memory should be added to the computer.

On virtual memory systems, if memory paging to disk is observed, a considerable performance penalty is incurred. Increasing available memory will speed the solution process dramatically. Also consider option [MemoryEmphasis](#) to conserve memory where possible.

Cplex performs an operation called refactorization at a frequency determined by the [ReInv](#) option setting. The longer Cplex works between refactorizations, the greater the amount of memory required to complete each iteration. Therefore, one means for conserving memory is to increase the refactorization frequency. Since refactorization is an expensive operation, increasing the refactorization frequency by reducing the [ReInv](#) option setting generally will slow performance. Cplex will automatically increase the refactorization frequency if it encounters low memory availability. This can be seen by watching the iteration log. The default log reports problem status at every refactorization. If the number of iterations between iteration log entries is decreasing, Cplex is increasing the refactorization frequency. Since Cplex might increase the frequency to once per iteration, the impact on performance can be dramatic. Providing additional memory should be beneficial.

CplexD also provides the option [FreeGAMSModel](#) to free some memory allocated by the GAMS link and making it available to Cplex. This only works when the GAMS parameter `SolveLink` is set 0 which should be always done when memory is tight because GAMS completely vacates memory.

The [Threads](#) options also has a significant impact on memory consumption. The concurrent solvers keep multiple copies of the problem in memory which double or even triples the amount of memory consumed. If memory tight, set the [Threads](#) parameter to 1.

5.15.6.2 Using Special Ordered Sets

For some models a special structure can be exploited. GAMS allows you to declare [SOS1](#) and [SOS2](#) variables (Special Ordered Sets of type 1 and 2).

In Cplex the definition for SOS1 variables is:

- A set of variables for which at most one variable may be non-zero.

The definition for SOS2 variables is:

- A set of variables for which at most two variables may be non-zero. If two variables are non-zero, they must be adjacent in the set.

5.15.6.3 Using Semi-Continuous and Semi-Integer Variables

GAMS allows the declaration of [semi-continuous](#) and [semi-integer](#) variables. These variable types are directly supported by GAMS/Cplex. For example:

```
SemiCont Variable x;  
x.lo = 3.2;  
x.up = 8.7;  
  
SemiInt Variable y;  
y.lo = 5;  
y.up = 10;
```

Variable x will be allowed to take on a value of 0.0 or any value between 3.2 and 8.7. Variable y will be allowed to take on a value of 0 or any integral value between 5 and 10.

5.15.6.4 Running Out of Memory for MIP Problems

The most common difficulty when solving MIP problems is running out of memory. This problem arises when the branch and bound tree becomes so large that insufficient memory is available to solve an LP subproblem. As memory gets tight, you may observe frequent warning messages while Cplex attempts to navigate through various operations within limited memory. If a solution is not found shortly the solution process will be terminated with an unrecoverable integer failure message.

The tree information saved in memory can be substantial. Cplex saves a basis for every unexplored node. When utilizing the best bound method of node selection, the list of such nodes can become very long for large or difficult problems. How large the unexplored node list can become is entirely dependent on the actual amount of physical memory available and the actual size of the problem. Certainly increasing the amount of memory available extends the problem solving capability. Unfortunately, once a problem has failed because of insufficient memory, you can neither project how much further the process needed to go nor how much memory would be required to ultimately solve it.

Memory requirements can be limited by using the [WorkMem](#), option with the [NodeFileInd](#) option. Setting [NodeFileInd](#) to 2 or 3 will cause Cplex to store portions of the branch and bound tree on disk whenever it grows to larger than the size specified by option [WorkMem](#). That size should be set to something less than the amount of physical memory available.

Another approach is to modify the solution process to utilize less memory.

- Set option [NodeSel](#) to use a best estimate strategy or, more drastically a depth-first-search. Depth first search rarely generates a large unexplored node list since Cplex will be diving deep into the branch and bound tree rather than jumping around within it.
- Set option [VarSel](#) to use strong branching. Strong branching spends extra computation time at each node to choose a better branching variable. As a result it generates a smaller tree. It is often faster overall, as well.
- On some problems, a large number of cuts will be generated without a correspondingly large benefit in solution speed. Cut generation can be turned off using option [Cuts](#).
- Set option [MemoryEmphasis](#) to instruct Cplex to conserve memory wherever possible.

5.15.6.5 Failing to Prove Integer Optimality

One frustrating aspect of the branch and bound technique for solving MIP problems is that the solution process can continue long after the best solution has been found. Remember that the branch and bound tree may be as large as 2^n nodes, where n equals the number of binary variables. A problem containing only 30 binary variables could produce a tree having over one billion nodes! If no other stopping criteria have been set, the process might continue ad infinitum until the search is complete or your computer's memory is exhausted.

In general you should set at least one limit on the optimization process before beginning an optimization. Setting limits ensures that an exhaustive tree search will terminate in reasonable time. Once terminated, you can rerun the problem using some different option settings.

5.15.6.6 Starting from a MIP Solution

You can provide a known solution (for example, from a MIP problem previously solved or from your knowledge of the problem) to serve as the first integer solution. When you provide such a starting solution, you may invoke relaxation induced neighborhood search (RINS heuristic) or solution polishing to improve the given solution. This first integer solution may include continuous and discrete variables of various types, such as semi-continuous variables or special ordered sets.

If you specify values for all discrete variables, GAMS/CPLEX will check the validity of the values as an integer-feasible solution; if you specify values for only a portion of the discrete variables, GAMS/CPLEX will attempt to fill in the missing values in a way that leads to an integer-feasible solution. If the specified values do not lead directly to an integer-feasible solution, GAMS/CPLEX will apply a quick heuristic to try to repair the MIP Start. The number of times that GAMS/CPLEX applies the heuristic is controlled by the repair tries parameter ([RepairTries](#)). If this process succeeds, the solution will be treated as an integer solution of the current problem.

A MIP start will only be used by GAMS/CPLEX if the [MipStart](#) parameter is set to 1. The starting values must be set via the `.L` variable attribute in the GAMS model before the solve statement.

5.15.6.7 Using the Feasibility Relaxation

The feasibility relaxation is enabled by the [FeasOpt](#) parameter in a CPLEX solver option file.

With the [FeasOpt](#) option CPLEX accepts an infeasible model and selectively relaxes the bounds and constraints in a way that minimizes a weighted penalty function. In essence, the feasible relaxation tries to suggest the least change that would achieve feasibility. It returns an infeasible solution to GAMS and marks the relaxations of bounds and constraints with the INFES marker in the solution section of the listing file.

By default all equations are candidates for relaxation and weighted equally but none of the variables can be relaxed. This default behavior can be modified by assigning relaxation preferences to variable bounds and constraints. These preferences can be conveniently specified with the [dot option FeasPref](#). A negative or zero preference means that the associated bound or constraint is not to be modified. The weighted penalty function is constructed from these preferences. The larger the preference, the more likely it will be that a given bound or constraint will be relaxed. However, it is not necessary to specify a unique preference for each bound or range. In fact, it is conventional to use only the values 0 (zero) and 1 (one) except when your knowledge of the problem suggests assigning explicit preferences.

Preferences can be specified through a CPLEX solver option file. The syntax is:

(variable or equation) .feaspref (value)

For example, suppose we have a GAMS declaration:

```
Set i /i1*i5/;
Set j /j2*j4/;
variable v(i,j); equation e(i,j);
```

Then, the relaxation preference in the `cplex.opt` file can be specified by:

```
feasopt 1
v.feaspref          1
v.feaspref('i1',*)  2
v.feaspref('i1','j2') 0

e.feaspref(*,'j1')   0
e.feaspref('i5','j4') 2
```

First we turn the feasible relaxation on. Furthermore, we specify that all variables `v(i,j)` have preference of 1, except variables over set element `i1`, which have a preference of 2. The variable over set element `i1` and `j2` has preference 0. Note that preferences are assigned in a procedural fashion so that preferences assigned later overwrite previous preferences. The same syntax applies for assigning preferences to equations as demonstrated above. If you want to assign a preference to all variables or equations in a model, use the keywords `variables` or `equations` instead of the individual variable and equations names (e.g. `variables.feaspref 1`).

The parameter [FeasOptMode](#) allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter `FeasOptMode` indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the relaxation (as a *sum* of required relaxations; as the *number* of constraints and bounds required to be relaxed; as a *sum of the squares* of required relaxations). Please check description of parameters [FeasOpt](#) and [FeasOptMode](#) for details. Also check example models `feasopt*` in the GAMS Model library.

5.15.6.8 Sensitivity Analysis

Sensitivity analysis (post-optimality analysis) in linear programming allows one to find out more about an optimal solution for a problem. In particular, objective ranging and right-hand-side ranging give information about how much an objective coefficient or a right-hand-side value can change without changing the optimal basis. In other words, they give information about how sensitive the optimal basis is to a change in the objective function or a right-hand-side.

Although not so much used for practical large scale problems and not available for mixed-integer or nonlinear models, ranging information can still be of use in some circumstances. This section describes how to produce ranging information with GAMS/CPLEX.

To obtain objective ranging information for a particular variable, the name of the GAMS variable should be specified with the [ObjRng](#) option. For example, to obtain ranging information for a variable `prod`, add the line

```
objrng prod
```

to a CPLEX options file. The [ObjRng](#) option can be repeated to specify ranging for more than one variable. To specify ranging for all variables, use the keyword `all`, i.e.,

```
objrng all
```

Similarly, to obtain right-hand-side ranging information for a particular equation, the name of the equation should be specified with the [RhsRng](#) option. Also this option can be repeated to obtain right-hand-side ranging information for several equations. To specify ranging for all equations use the keyword `all`.

As an example, consider solving the model `[TRANSPORT]` from the GAMS model library with CPLEX and options file

```
objrng all
rhsrng all
```

This gives the following table in the listing file:

EQUATION NAME	LOWER	CURRENT	UPPER
-----	-----	-----	-----
cost	-INF	0	+INF
supply(seattle)	300	350	625
supply(san-diego)	550	600	+INF
demand(new-york)	50	325	375
demand(chicago)	25	300	350
demand(topeka)	0	275	325

VARIABLE NAME	LOWER	CURRENT	UPPER
-----	-----	-----	-----
x(seattle, new-york)	0.216	0.225	0.225
x(seattle, chicago)	0	0.153	0.162
x(seattle, topeka)	0.126	0.162	+INF
x(san-diego, new-york)	0.225	0.225	0.234
x(san-diego, chicago)	0.153	0.162	+INF
x(san-diego, topeka)	0	0.126	0.162
z	-INF	1	+INF

If obtaining ranging information in a listing file is not sufficient, option [RngRestart](#) can be used to specify a file to which to write ranging information in GAMS syntax. For example, using an options file containing

```
rhsrng supply
rhsrng demand
rngrestart ranges.inc
```

will result in a file named `ranges.inc` being written with the following content:

```
* Include file with ranging information
* The set RNLIM /LO,UP/ is assumed to be
* declared.
```

```
PARAMETER supplyRNG(i,RNLIM) /
seattle.LO          300
seattle.UP          625
san-diego.LO        550
san-diego.UP        +INF
/;
PARAMETER demandRNG(j,RNLIM) /
new-york.LO         50
new-york.UP         375
chicago.LO         25
chicago.UP         350
topeka.LO           0
topeka.UP           325
/;
```

For each equation specified, the ranging information is stored in a newly declared corresponding GAMS parameter. The name of the parameter is based on the name of the equation, but with `RNG` appended. The user is responsible for ensuring that the new name does not exceed the maximum symbol name length of GAMS identifiers. Further, the domain list of the new parameter is the same as the domain list for the corresponding equation with an additional dimension added to the end. The user is responsible for ensuring that the new parameter does not exceed the maximum number of index positions.

5.15.7 GAMS/Cplex Log File

Cplex reports its progress by writing to the GAMS log file as the problem solves. Normally the GAMS log file is directed to the computer screen.

The log file shows statistics about the presolve and continues with an iteration log.

For the primal simplex algorithm, the iteration log starts with the iteration number followed by the scaled infeasibility value. Once feasibility has been attained, the objective function value is listed instead. At the default value for option `simdisplay` there is a log line for each refactorization. The screen log has the following appearance:

```
Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time = 0.01 sec.
Using conservative initial basis.
```

```
Iteration log . . .
Iteration: 1 Scaled infeas = 193998.067174
Iteration: 29 Objective = -3484.286415
Switched to devex.
Iteration: 98 Objective = -1852.931117
Iteration: 166 Objective = -349.706562
```

Optimal solution found.

```
Objective : 901.161538
```

The iteration log for the dual simplex algorithm is similar, but the dual infeasibility and dual objective are reported instead of the corresponding primal values:

```
Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time =    0.01 sec.

Iteration log . . .
Iteration:    1   Scaled dual infeas =          3.890823
Iteration:   53   Dual objective      =         4844.392441
Iteration:  114   Dual objective      =         1794.360714
Iteration:  176   Dual objective      =         1120.183325
Iteration:  238   Dual objective      =          915.143030
Removing shift (1).
```

Optimal solution found.

Objective : 901.161538

The log for the network algorithm adds statistics about the extracted network and a log of the network iterations. The optimization is finished by one of the simplex algorithms and an iteration log for that is produced as well.

```
Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time =    0.01 sec.
Extracted network with 25 nodes and 116 arcs.
Extraction time =  -0.00 sec.
Iteration log . . .
Iteration:    0   Infeasibility      =         1232.378800 (-1.32326e+12)

Network - Optimal: Objective =    1.5716820779e+03
Network time =    0.01 sec.  Iterations = 26 (24)
```

```
Iteration log . . .
Iteration:    1   Scaled infeas =         212696.154729
Iteration:   62   Scaled infeas =         10020.401232
Iteration:  142   Scaled infeas =          4985.200129
Switched to devex.
Iteration:  217   Objective      =         -3883.782587
Iteration:  291   Objective      =         -1423.126582
```

Optimal solution found.

Objective : 901.161538

The log for the barrier algorithm adds various algorithm specific statistics about the problem before starting the iteration log. The iteration log includes columns for primal and dual objective values and infeasibility values. A special log follows for the crossover to a basic solution.

Tried aggregator 1 time.
 LP Presolve eliminated 2 rows and 39 columns.
 Aggregator did 30 substitutions.
 Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
 Presolve time = 0.02 sec.
 Number of nonzeros in lower triangle of A*A' = 6545
 Using Approximate Minimum Degree ordering
 Total time for automatic ordering = 0.01 sec.
 Summary statistics for Cholesky factor:

Rows in Factor = 243
 Integer space required = 578
 Total non-zeros in factor = 8491
 Total FP ops to factor = 410889

Using devex.
Total crossover time = 0.02 sec.

Optimal solution found.

Objective : 901.161540

```

For MIP problems, during the branch and bound search, Cplex reports the node number, the number of nodes left, the value of the Objective function, the number of integer variables that have fractional values, the current best integer solution, the best relaxed solution at a node and an iteration count. The last column show the current optimality gap as a percentage. CPLEX logs an asterisk (*) in the left-most column for any node where it finds an integer-feasible solution or new incumbent. The + denotes an incumbent generated by the heuristic.

```

5.15.8 Detailed Descriptions of CPLEX Options

These options should be entered in the options file after setting the GAMS ModelName.OptFile parameter to 1. The name of the options file is `cplex.opt`. The options file is case insensitive and the keywords should be given in full.

advind (*integer*): advanced basis use ↩

Use an Advanced Basis. GAMS/Cplex will automatically use an advanced basis from a previous solve statement. The GAMS `BRatio` option can be used to specify when not to use an advanced basis. The Cplex option `AdvInd` can be used to ignore a basis passed on by GAMS (it overrides `BRatio`).

Default: determined by GAMS `Bratio`

value	meaning
0	Do not use advanced basis
1	Use advanced basis if available
2	Crash an advanced basis if available (use basis with presolve)

aggcutlim (*integer*): aggregation limit for cut generation ↔

Limits the number of constraints that can be aggregated for generating flow cover and mixed integer rounding cuts. For most purposes, the default will be satisfactory.

Default: 3

aggfill (*integer*): aggregator fill parameter ↔

Aggregator fill limit. If the net result of a single substitution is more non-zeros than the setting of the `AggFill` parameter, the substitution will not be made.

Default: 10

aggind (*integer*): aggregator on/off ↔

This option, when set to a nonzero value, will cause the Cplex aggregator to use substitution where possible to reduce the number of rows and columns in the problem. If set to a positive value, the aggregator will be applied the specified number of times, or until no more reductions are possible. At the default value of -1, the aggregator is applied once for linear programs and an unlimited number of times for mixed integer problems.

Default: -1

value	meaning
-1	Once for LP, unlimited for MIP
0	Do not use
>0	Aggregator will be applied the specified number of times

auxrootthreads (*integer*): number of threads for auxiliary tasks at the root node ↔

Partitions the number of threads for CPLEX to use for auxiliary tasks while it solves the root node of a problem. On a system that offers N processors or N global threads, if you set this parameter to n , where $N > n > 0$ then CPLEX uses at most n threads for auxiliary tasks and at most $N - n$ threads to solve the root node. See also the parameter [Threads](#).

You cannot set n , the value of this parameter, to a value greater than or equal to N , the number of processors or global threads offered on your system. In other words, when you set this parameter to a value other than its default, that value must be strictly less than the number of processors or global threads on your system. Independent of the auxiliary root threads parameter, CPLEX will never use more threads than those defined by the global default thread count parameter. CPLEX also makes sure that there is at least one thread

available for the main root tasks. For example, if you set the global threads parameter to 3 and the auxiliary root threads parameter to 4, CPLEX still uses only two threads for auxiliary root tasks in order to keep one thread available for the main root tasks. At its default value, 0 (zero), CPLEX automatically chooses the number of threads to use for the primary root tasks and for auxiliary tasks. The number of threads that CPLEX uses to solve the root node depends on several factors: 1) the number of processors available on your system; 2) the number of threads available to your application on your system (for example, as a result of limited resources or competition with other applications); 3) the value of the global default thread count parameter [Threads](#).

Default: 0

value	meaning
-1	Off: do not use additional threads for auxiliary tasks
0	Automatic: let CPLEX choose the number of threads to use
$N > n > 0$	Use n threads for auxiliary root tasks

baralg (*integer*): algorithm selection [↔](#)

Selects which barrier algorithm to use. The default setting of 0 uses the infeasibility-estimate start algorithm for MIP subproblems and the standard barrier algorithm, option 3, for other cases. The standard barrier algorithm is almost always fastest. The alternative algorithms, options 1 and 2, may eliminate numerical difficulties related to infeasibility, but will generally be slower.

Default: 0

value	meaning
0	Same as 1 for MIP subproblems, 3 otherwise
1	Infeasibility-estimate start
2	Infeasibility-constant start
3	standard barrier algorithm

barcolnz (*integer*): dense column handling [↔](#)

Determines whether or not columns are considered dense for special barrier algorithm handling. At the default setting of 0, this parameter is determined dynamically. Values above 0 specify the number of entries in columns to be considered as dense.

Default: 0

barcrossalg (*integer*): barrier crossover method [↔](#)

Selects which crossover method is used at the end of a barrier optimization. To turn off crossover set [SolutionType](#) to 2.

Default: 0

value	meaning
0	Automatic
1	Primal crossover
2	Dual crossover

bardisplay (*integer*): progress display level ↩

Determines the level of progress information to be displayed while the barrier method is running.

Default: 1

value	meaning
0	No progress information
1	Display normal information
2	Display diagnostic information

barepcomp (*real*): convergence tolerance ↩

Determines the tolerance on complementarity for convergence of the barrier algorithm. The algorithm will terminate with an optimal solution if the relative complementarity is smaller than this value.

Default: 1e-008

bargrowth (*real*): unbounded face detection ↩

Used by the barrier algorithm to detect unbounded optimal faces. At higher values, the barrier algorithm will be less likely to conclude that the problem has an unbounded optimal face, but more likely to have numerical difficulties if the problem does have an unbounded face.

Default: 1e+012

baritlim (*integer*): iteration limit ↩

Determines the maximum number of iterations for the barrier algorithm. When set to 0, no Barrier iterations occur, but problem *setup* occurs and information about the setup is displayed (such as Cholesky factorization information). When left at the default value, there is no explicit limit on the number of iterations.

Default: large

barmaxcor (*integer*): maximum correction limit ↩

Specifies the maximum number of centering corrections that should be done on each iteration. Larger values may improve the numerical performance of the barrier algorithm at the expense of computation time. The default of -1 means the number is automatically determined.

Default: -1

barobjrng (*real*): maximum objective function ↩

Determines the maximum absolute value of the objective function. The barrier algorithm looks at this limit to detect unbounded problems.

Default: 1e+020

barorder (*integer*): row ordering algorithm selection ↩

Determines the ordering algorithm to be used by the barrier method. By default, Cplex attempts to choose the most effective of the available alternatives. Higher numbers tend to favor better orderings at the expense of longer ordering run times.

Default: 0

value	meaning
0	Automatic
1	Approximate Minimum Degree (AMD)
2	Approximate Minimum Fill (AMF)
3	Nested Dissection (ND)

barqcpepcomp (*real*): convergence tolerance for the barrier optimizer for QCPs ↔

Range: [1e-012, 1e+075]

Default: 1e-007

barstartalg (*integer*): barrier starting point algorithm ↔

This option sets the algorithm to be used to compute the initial starting point for the barrier solver. The default starting point is satisfactory for most problems. Since the default starting point is tuned for primal problems, using the other starting points may be worthwhile in conjunction with the [PreDual](#) parameter.

Default: 1

value	meaning
1	default primal, dual is 0
2	default primal, estimate dual
3	primal average, dual is 0
4	primal average, estimate dual

bbinterval (*integer*): best bound interval ↔

Set interval for selecting a best bound node when doing a best estimate search. Active only when [NodeSel](#) is 2 (best estimate). Decreasing this interval may be useful when best estimate is finding good solutions but making little progress in moving the bound. Increasing this interval may help when the best estimate node selection is not finding any good integer solutions. Setting the interval to 1 is equivalent to setting [NodeSel](#) to 1.

Default: 7

bendersfeascuttol (*real*): Tolerance for whether a feasibility cut has been violated in Benders decomposition ↔

Default: 1e-006

bendersoptcuttol (*real*): Tolerance for optimality cuts in Benders decomposition ↔

Default: 1e-006

.benderspartition (*integer*): Benders partition ↔

Default: 0

benderspartitioninstage (*boolean*): Benders partition through stage variable suffix ↔

Default: 0

bendersstrategy (*integer*): Benders decomposition algorithm as a strategy ↩

Given a formulation of a problem, CPLEX can decompose the model into a single master and (possibly multiple) subproblems. To do so, CPLEX can make use of annotations that you supply for your model. The strategy can be applied to mixed-integer linear programs (MILP). For certain types of problems, this approach offers significant performance improvements as subproblems can be solved in parallel.

For mixed integer programs (MIP), under certain conditions, CPLEX can apply Benders algorithm to improve the search to find more feasible solutions more quickly.

Default: 0

value	meaning
-1	Off Execute conventional branch and bound; ignore any Benders annotations. That is, do not use Benders algorithm even if a Benders partition of the current model is present
0	Automatic If annotations specifying a Benders partition of the current model are available, CPLEX attempts to decompose the model. CPLEX uses the master as given by the annotations, and attempts to partition the subproblems further, if possible, before applying Benders algorithm to solve the model. If the user supplied annotations, but the annotations supplied do not lead to a complete decomposition into master and disjoint subproblems (that is, if the annotations are wrong in that sense), CPLEX produces an error.
1	Apply user annotations CPLEX applies Benders algorithm to a decomposition based on annotations supplied by the user. If no annotations to decompose the model are available, this setting produces an error. If the user supplies annotations, but the supplied annotations do not lead to a complete partition of the original model into disjoint master and subproblems, then this setting produces an error.
2	Apply user annotations with automatic support for subproblems CPLEX accepts the master as given and attempts to decompose the remaining elements into disjoint subproblems to assign to workers. It then solves the Benders decomposition of the model. If no annotations to decompose the model are available, this setting produces an error. If the user supplies annotations, but the supplied annotations do not lead to a complete partition of the original model into disjoint master and subproblems, then this setting produces an error.
3	Apply automatic decomposition CPLEX ignores any annotation supplied with the model; CPLEX applies presolve; CPLEX then automatically generates a Benders partition, putting integer variables in master and continuous linear variables into disjoint subproblems. CPLEX then solves the Benders decomposition of the model. If the problem is a strictly linear program (LP), that is, there are no integer-constrained variables to put into master, then CPLEX reports an error. If the problem is a mixed integer linear program (MILP) where all variables are integer-constrained, (that is, there are no continuous linear variables to decompose into disjoint subproblems) then CPLEX reports an error.

bndstrenind (*integer*): bound strengthening ↩

Use bound strengthening when solving mixed integer problems. Bound strengthening tightens the bounds on variables, perhaps to the point where the variable can be fixed and thus removed from consideration during the branch and bound algorithm. This reduction is usually beneficial, but occasionally, due to its iterative nature, takes a long time.

Default: -1

value	meaning
-1	Determine automatically
0	Don't use bound strengthening
1	Use bound strengthening

bqpcuts (*integer*): boolean quadric polytope cuts for nonconvex QP or MIQP solved to global optimality ↩

Default: 0

value	meaning
-1	Do not generate BQP cuts
0	Determined automatically
1	Generate BQP cuts moderately
2	Generate BQP cuts aggressively
3	Generate BQP cuts very aggressively

brdir (*integer*): set branching direction ↩

Used to decide which branch (up or down) should be taken first at each node.

Default: 0

value	meaning
-1	Down branch selected first
0	Algorithm decides
1	Up branch selected first

bttol (*real*): backtracking limit ↩

This option controls how often backtracking is done during the branching process. At each node, Cplex compares the objective function value or estimated integer objective value to these values at parent nodes; the value of the **bttol** parameter dictates how much relative degradation is tolerated before backtracking. Lower values tend to increase the amount of backtracking, making the search more of a pure best-bound search. Higher values tend to decrease the amount of backtracking, making the search more of a depth-first search. This parameter is used only once a first integer solution is found or when a cutoff has been specified.

Range: [0, 1]

Default: 0.9999

calcqcpduals (*integer*): calculate the dual values of a quadratically constrained problem ↩

Default: 1

value	meaning
0	Do not calculate dual values
1	Calculate dual values as long as it does not interfere with presolve reductions
2	Calculate dual values and disable any presolve reductions that would interfere

cliques (*integer*): clique cut generation ↩

Determines whether or not clique cuts should be generated during optimization.

Default: 0

value	meaning
-1	Do not generate clique cuts
0	Determined automatically
1	Generate clique cuts moderately
2	Generate clique cuts aggressively
3	Generate clique cuts very aggressively

clocktype (*integer*): clock type for computation time ↩

Decides how computation times are measured for both reporting performance and terminating optimization when a time limit has been set. Small variations in measured time on identical runs may be expected on any computer system with any setting of this parameter.

Default: 2

value	meaning
0	Automatic
1	CPU time
2	Wall clock time

clonelog (*integer*): enable clone logs ↩

The clone logs contain information normally recorded in the ordinary log file but inconvenient to send through the normal log channel in case of parallel execution. The information likely to be of most interest to you are special messages, such as error messages, that result from calls to the LP optimizers called for the subproblems. The clone log files are named cloneK.log, where *K* is the index of the clone, ranging from 0 (zero) to the number of threads minus one. Since the clones are created at each call to a parallel optimizer and discarded when it exits, the clone logs are opened at each call and closed at each exit. The clone log files are not removed when the clones themselves are discarded.

Default: 0

value	meaning
-1	Clone log files off
0	Automatic
1	Clone log files on

coeredind (*integer*): coefficient reduction on/off ↩

Coefficient reduction is a technique used when presolving mixed integer programs. The benefit is to improve the objective value of the initial (and subsequent) linear programming relaxations by reducing the number of non-integral vertexes. However, the linear programs generated at each node may become more difficult to solve.

Default: -1

value	meaning
-1	Automatic
0	Do not use coefficient reduction
1	Reduce only to integral coefficients
2	Reduce all potential coefficients
3	Reduce aggressively with tilting

computeserver (*string*): address and port of Cplex remote object server ↩

This option will use a remote machine to solve the model. The option is specified as **name:port** where **name** is the machine name or IP address of the remote server and **port** is the port number the Cplex remote server listen for work. On the remote server, a full Cplex installation (not just GAMS/Cplex) is required. On the server, one needs to start **cplex -worker=tcPIP -address=name:port** with the same name/port as in this option.

covers (*integer*): cover cut generation ↩

Determines whether or not cover cuts should be generated during optimization.

Default: 0

value	meaning
-1	Do not generate cover cuts
0	Determined automatically
1	Generate cover cuts moderately
2	Generate cover cuts aggressively
3	Generate cover cuts very aggressively

cpumask (*string*): switch and mask to bind threads to processors ↩

The value of this parameter serves as a switch to turn on (or to turn off) CPLEX binding of multiple threads to multiple processors on platforms where this feature is available. Hexadecimal values of this parameter serve as a mask to specify to CPLEX which processors (or cores) to use in binding multiple threads to multiple processors. CPU binding is also sometimes known as *processor affinity*. CPU binding reduces the variability of CPLEX runs. On some occasions, running the same CPLEX on the same (non trivial) models would produce a big variation in runtime, e.g. 1000 seconds versus 900 seconds on a 12 core machine. These differences happen while CPLEX still gets exactly the same results and executes the exact same path, thanks to its completely deterministic algorithms. Running the same tests with CPU binding enabled reduced this variability in running time significantly.

If not set to **off** or **auto** CPLEX treats the value of this parameter as a string that resembles a hexadecimal number without the usual 0x prefix. A valid string consists of these elements: a) any digit from 0 (zero) through 9 (inclusive), b) any lower case character in the range a through f (inclusive), and c) any upper case character in the range A through F (inclusive). CPLEX rejects a string containing any other digits or characters than those.

When the value of this parameter is a valid string, each bit of this string corresponds to a central processing unit (CPU), that is, to a processor or core. The lowest order bit of the string corresponds to the first logical CPU, and the highest order corresponds to the last logical CPU. For example, 00000001 designates processor #0, 00000003 designates processors #0 and #1, FFFFFFFF designates all processors #0 through #31. CPLEX uses the *i*th CPU if and only if the *i*th bit of this string is set to 1 (one). Tip: For GNU/Linux users, this parameter behaves like the **taskset** command (except that this parameter lacks the prefix 0x).

If this CPU mask parameter is set to a valid string that designates a hexadecimal number, but global **Threads** count is set to 0 (zero), then CPLEX still starts as many threads as the number of cores on the machine, but only the cores enabled in the mask will be used.

For example, if a user sets this CPU mask parameter to the hexadecimal value "f" on a 16-core machine, and the user sets the global **Threads** count to 0 (zero), the result is 16 threads. These 16 threads will be bound to the first four cores in a round-robin way: threads 1,5,9,13 to core 1, threads 2,6,10,14 to core 2 and so on. This situation is probably not what the user intended. Therefore, if you set this CPU mask parameter, then you should also set global threads count; indeed, you should set the threads parameter to the number of active cores designated by the mask.

For example, on a 16 core machine, consider the difference between the value "off" and the value *ffff*. If the value of this parameter is "off" CPLEX does no binding. If the value of this parameter is *ffff*, CPLEX binds threads to cores.

Default: **auto**

value	meaning
auto	CPLEX decides whether to bind threads to cores (or processors)
off	CPLEX performs no binding
hex	CPLEX binds the threads in round-robin fashion to the cores specified by the mask

craind (*integer*): crash strategy (used to obtain starting basis) ↔

The crash option biases the way Cplex orders variables relative to the objective function when selecting an initial basis.

Default: **1**

value	meaning
-1	Primal: alternate ways of using objective coefficients. Dual: aggressive starting basis
0	Primal: ignore objective coefficients during crash. Dual: aggressive starting basis
1	Primal: alternate ways of using objective coefficients. Dual: default starting basis

cutlo (*real*): lower cutoff for tree search ↔

Sets the lower cutoff tolerance. When the problem is a maximization problem, CPLEX cuts off or discards solutions that are less than the specified cutoff value. If the model has no solution with an objective value greater than or equal to the cutoff value, then CPLEX declares the model infeasible. In other words, setting the lower cutoff value *c* for a maximization problem is similar to adding this constraint to the objective function of the model: **obj>=c**.

This option overrides the GAMS Cutoff setting.

This parameter is not effective with FeasOpt. FeasOpt cannot analyze an infeasibility introduced by this parameter. If you want to analyze such a condition, add an explicit objective constraint to your model instead.

Default: **-1e+075**

cutpass (*integer*): maximum number of cutting plane passes ↔

Sets the upper limit on the number of passes that will be performed when generating cutting planes on a mixed integer model.

Default: **0**

value	meaning
-1	None
0	Automatically determined
>0	Maximum passes to perform

cuts (*string*): default cut generation ↔

Allows generation setting of all optional cuts at once. This is done by changing the meaning of the default value (0: automatic) for the various Cplex cut generation options. The options affected are [Cliques](#), [Covers](#), [DisjCuts](#), [FlowCovers](#), [FlowPaths](#), [FracCuts](#), [GUBCovers](#), [ImplBd](#), [LiftProjCuts](#), [MFCuts](#), [MIRCuts](#), and [Symmetry](#).

Default: 0

value	meaning
-1	Do not generate cuts
0	Determined automatically
1	Generate cuts moderately
2	Generate cuts aggressively
3	Generate cuts very aggressively
4	Generate cuts highly aggressively
5	Generate cuts extremely aggressively

cutsfactor (*real*): cut limit ↔

This option limits the number of cuts that can be added. For values between zero and one inclusive (that is, in the range [0.0, 1.0], CPLEX generates no cuts.

For values strictly greater than 1.0 (one), CPLEX limits the number of rows in the model with cuts added.

The limit on this total is the product of *CutsFactor* times the original number of rows. If CPLEX has presolved the model, the *original number of rows* is the number of rows in the presolved model. (This behavior with respect to a presolved model is unchanged.)

CPLEX regards negative values of this parameter as equivalent to the default value -1.0. That is, a negative value specifies no particular limit on the number of cuts. CPLEX computes and dynamically adjusts such a limit automatically

Default: -1

cutup (*real*): upper cutoff for tree search ↔

Sets the upper cutoff tolerance. When the problem is a minimization problem, CPLEX cuts off or discards any solutions that are greater than the specified upper cutoff value. If the model has no solution with an objective value less than or equal to the cutoff value, CPLEX declares the model infeasible. In other words, setting an upper cutoff value *c* for a minimization problem is similar to adding this constraint to the objective function of the model: `obj<=c`.

This option overrides the GAMS Cutoff setting.

This parameter is not effective with [FeasOpt](#). [FeasOpt](#) cannot analyze an infeasibility introduced by this parameter. If you want to analyze such a condition, add an explicit objective constraint to your model instead.

Default: 1e+075

datacheck (*integer*): controls data consistency checking and modeling assistance ↩

When the value of this parameter is set to level 2, CPLEX turns on both data consistency checking and modeling assistance. At this level, CPLEX issues warnings at the start of the optimization about disproportionate values (too large, too small) in coefficients, bounds, and righthand sides (RHS).

Default: 0

value	meaning
0	Data checking off
1	Data checking on
2	Data checking and model assistance on

depend (*integer*): dependency checker on/off ↩

This option determines if and when the dependency checker will be used.

Default: -1

value	meaning
-1	Automatic
0	Turn off dependency checking
1	Turn on only at the beginning of preprocessing
2	Turn on only at the end of preprocessing
3	Turn on at the beginning and at the end of preprocessing

dettlim (*real*): deterministic time limit ↩

Sets a time limit expressed in ticks, a unit to measure work done deterministically.

The length of a deterministic tick may vary by platform. Nevertheless, ticks are normally consistent measures for a given platform (combination of hardware and software) carrying the same load. In other words, the correspondence of ticks to clock time depends on the hardware, software, and the current load of the machine. For the same platform and same load, the ratio of ticks per second stays roughly constant, independent of the model solved. However, for very short optimization runs, the variation of this ratio is typically high.

Default: 1e+075

disjcuts (*integer*): disjunctive cuts generation ↩

Determines whether or not to generate disjunctive cuts during optimization. At the default of 0, generation is continued only if it seems to be helping.

Default: 0

value	meaning
-1	Do not generate disjunctive cuts
0	Determined automatically
1	Generate disjunctive cuts moderately
2	Generate disjunctive cuts aggressively
3	Generate disjunctive cuts very aggressively

divetype (*integer*): MIP dive strategy ↩

The MIP traversal strategy occasionally performs probing dives, where it looks ahead at both children nodes before deciding which node to choose. The default (automatic) setting chooses when to perform a probing dive, and the other two settings direct Cplex when to perform probing dives: never or always.

Default: 0

value	meaning
0	Automatic
1	Traditional dive
2	Probing dive
3	Guided dive

.divflt (*real*): solution pool range filter coefficients ↩

A diversity filter for a solution pool (see option [SolnPool](#)) allows you generate solutions that are similar to (or different from) a set of reference values that you specify for a set of binary variables. In particular, you can use a diversity filter to generate more solutions that are similar to an existing solution or to an existing partial solution.

A diversity filter drives the search for multiple solutions toward new solutions that satisfy a measure of diversity specified in the filter. This diversity measure applies only to binary variables. Potential new solutions are compared to a reference set. This reference set is specified with this dot option. If no reference set is specified, the difference measure will be computed relative to the other solutions in the pool. The diversity measure is computed by summing the pair-wise absolute differences from solution and the reference values.

Default: 0

divfltlo (*real*): lower bound on diversity ↩

Please check option [DivFlt](#) for general information on a diversity filter.

If you specify a lower bound on the diversity using `DivFltLo`, Cplex will look for solutions that are different from the reference values. In other words, you can say, Give me solutions that differ by at least this amount in this set of variables.

Default: `mindouble`

divfltup (*real*): upper bound on diversity ↩

Please check option [DivFlt](#) for general information on a diversity filter.

If you specify an upper bound on diversity `DivFltUp`, Cplex will look for solutions similar to the reference values. In other words, you can say, Give me solutions that are close to this one, within this set of variables.

Default: `maxdouble`

dpriind (*integer*): dual simplex pricing ↩

Pricing strategy for dual simplex method. Consider using dual steepest-edge pricing. Dual steepest-edge is particularly efficient and does not carry as much computational burden as the primal steepest-edge pricing.

Default: 0

value	meaning
0	Determined automatically
1	Standard dual pricing
2	Steepest-edge pricing
3	Steepest-edge pricing in slack space
4	Steepest-edge pricing, unit initial norms
5	Devex pricing

dynamicrows (*integer*): switch for dynamic management of rows ↵

This parameter specifies how CPLEX should manage rows in the current model during dual simplex optimization. More specifically, this parameter controls the use of the kernel simplex method (KSM) for the dual simplex algorithm. That is, CPLEX dynamically adjusts the dimensions of the basis matrix during execution of the dual simplex algorithm, according to the settings of this parameter.

When the value of this parameter is -1, its default value, this parameter specifies that the user wants CPLEX to manage rows dynamically, adjusting the dimensions of the basis matrix during dual simplex optimization. When it is set to 0, this parameter specifies that CPLEX must keep all rows. When it is set to 1, this parameter specifies that CPLEX can keep or discard rows according to its internal calculations.

Default: -1

value	meaning
-1	Automatic
0	Keep all rows
1	Manage rows

eachcutlim (*integer*): sets a limit for each type of cut ↵

This parameter allows you to set a uniform limit on the number of cuts of each type that Cplex generates. By default, the limit is a large integer; that is, there is no effective limit by default.

Tighter limits on the number of cuts of each type may benefit certain models. For example, a limit on each type of cut will prevent any one type of cut from being created in such large number that the limit on the total number of all types of cuts is reached before other types of cuts have an opportunity to be created. A setting of 0 means no cuts.

This parameter does not influence the number of Gomory cuts. For means to control the number of Gomory cuts, see also the fractional cut parameters: [FracCand](#), [FracCuts](#), and [FracPass](#).

Default: 2100000000

epagap (*real*): absolute stopping tolerance ↵

Synonym: optca

Absolute tolerance on the gap between the best integer objective and the objective of the best node remaining. When the value falls below the value of the **epagap** setting, the optimization is stopped. This option overrides GAMS OptCA which provides its initial value.

Default: GAMS OptCA

epgap (*real*): relative stopping tolerance ↔

Synonym: optcr

Relative tolerance on the gap between the best integer objective and the objective of the best node remaining. When the value falls below the value of the **epgap** setting, the mixed integer optimization is stopped. Note the difference in the Cplex definition of the relative tolerance with the GAMS definition. This option overrides GAMS OptCR which provides its initial value.

Range: [0, 1]

Default: GAMS OptCR

epint (*real*): integrality tolerance ↔

Integrality Tolerance. This specifies the amount by which an integer variable can be different than an integer and still be considered feasible.

Range: [0, 0.5]

Default: 1e-005

epmrk (*real*): Markowitz pivot tolerance ↔

The Markowitz tolerance influences pivot selection during basis factorization. Increasing the Markowitz threshold may improve the numerical properties of the solution.

Range: [0.0001, 0.99999]

Default: 0.01

epopt (*real*): optimality tolerance ↔

The optimality tolerance influences the reduced-cost tolerance for optimality. This option setting governs how closely Cplex must approach the theoretically optimal solution.

Range: [1e-009, 0.1]

Default: 1e-006

eppper (*real*): perturbation constant ↔

Perturbation setting. Highly degenerate problems tend to stall optimization progress. Cplex automatically perturbs the variable bounds when this occurs. Perturbation expands the bounds on every variable by a small amount thereby creating a different but closely related problem. Generally, the solution to the less constrained problem is easier to solve. Once the solution to the perturbed problem has advanced as far as it can go, Cplex removes the perturbation by resetting the bounds to their original values.

If the problem is perturbed more than once, the perturbation constant is probably too large. Reduce the **eppper** option to a level where only one perturbation is required. Any value greater than or equal to 1.0e-8 is valid.

Default: 1e-006

eprhs (*real*): feasibility tolerance ↔

Feasibility tolerance. This specifies the degree to which a problem's basic variables may violate their bounds. This tolerance influences the selection of an optimal basis and can be reset to a higher value when a problem is having difficulty maintaining feasibility during optimization. You may also wish to lower this tolerance after finding an optimal solution if there is any doubt that the solution is truly optimal. If the feasibility tolerance is set too low, Cplex may falsely conclude that a problem is infeasible.

Range: [1e-009, 0.1]

Default: 1e-006

feasopt (*boolean*): computes a minimum-cost relaxation to make an infeasible model feasible ↵

With **Feasopt** turned on, a minimum-cost relaxation of the right hand side values of constraints or bounds on variables is computed in order to make an infeasible model feasible. It marks the relaxed right hand side values and bounds in the solution listing.

Several options are available for the metric used to determine what constitutes a minimum-cost relaxation which can be set by option **FeasOptMode**.

Feasible relaxations are available for all problem types with the exception of quadratically constraint problems.

Default: 0

value	meaning
0	Turns Feasible Relaxation off
1	Turns Feasible Relaxation on

feasoptmode (*integer*): mode of FeasOpt ↵

The parameter **FeasOptMode** allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter **FeasOptMode** indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the minimality of the relaxation (as a *sum* of required relaxations; as the *number* of constraints and bounds required to be relaxed; as a *sum of the squares* of required relaxations).

Default: 0

value	meaning
0	Minimize sum of relaxations Minimize the sum of all required relaxations in first phase only
1	Minimize sum of relaxations and optimize Minimize the sum of all required relaxations in first phase and execute second phase to find optimum among minimal relaxations
2	Minimize number of relaxations Minimize the number of constraints and bounds requiring relaxation in first phase only
3	Minimize number of relaxations and optimize Minimize the number of constraints and bounds requiring relaxation in first phase and execute second phase to find optimum among minimal relaxations

value	meaning
4	Minimize sum of squares of relaxations Minimize the sum of squares of required relaxations in first phase only
5	Minimize sum of squares of relaxations and optimize Minimize the sum of squares of required relaxations in first phase and execute second phase to find optimum among minimal relaxations

.feaspref (*real*): feasibility preference ↩

You can express the costs associated with relaxing a bound or right hand side value during a **FeasOpt** run through the **.feaspref** option. The input value denotes the users willingness to relax a constraint or bound. More precisely, the reciprocal of the specified value is used to weight the relaxation of that constraint or bound. The user may specify a preference value less than or equal to 0 (zero), which denotes that the corresponding constraint or bound must not be relaxed.

Default: 1

flowcovers (*integer*): flow cover cut generation ↩

Determines whether or not flow cover cuts should be generated during optimization.

Default: 0

value	meaning
-1	Do not generate flow cover cuts
0	Determined automatically
1	Generate flow cover cuts moderately
2	Generate flow cover cuts aggressively

flowpaths (*integer*): flow path cut generation ↩

Determines whether or not flow path cuts should be generated during optimization. At the default of 0, generation is continued only if it seems to be helping.

Default: 0

value	meaning
-1	Do not generate flow path cuts
0	Determined automatically
1	Generate flow path cuts moderately
2	Generate flow path cuts aggressively

folding (*integer*): LP folding will be attempted during the preprocessing phase ↩

Default: -1

value	meaning
-1	Automatic
0	Turn off folder
1	Moderate level of folding

value	meaning
2	Aggressive level of folding
3	Very aggressive level of folding
4	Highly aggressive level of folding
5	Extremely aggressive level of folding

fpheur (*integer*): feasibility pump heuristic [↔](#)

Controls the use of the feasibility pump heuristic for mixed integer programming (MIP) models.

Default: 0

value	meaning
-1	Turns Feasible Pump heuristic off
0	Automatic
1	Apply the feasibility pump heuristic with an emphasis on finding a feasible solution
2	Apply the feasibility pump heuristic with an emphasis on finding a feasible solution with a good objective value

fraccand (*integer*): candidate limit for generating Gomory fractional cuts [↔](#)

Limits the number of candidate variables for generating Gomory fractional cuts.

Default: 200

fraccuts (*integer*): Gomory fractional cut generation [↔](#)

Determines whether or not Gomory fractional cuts should be generated during optimization.

Default: 0

value	meaning
-1	Do not generate Gomory fractional cuts
0	Determined automatically
1	Generate Gomory fractional cuts moderately
2	Generate Gomory fractional cuts aggressively

fracpass (*integer*): maximum number of passes for generating Gomory fractional cuts [↔](#)

Sets the upper limit on the number of passes that will be performed when generating Gomory fractional cuts on a mixed integer model. Ignored if parameter [FracCuts](#) is set to a nonzero value.

Default: 0

value	meaning
0	0 Automatically determined
>0	Maximum passes to perform

freegamsmodel (*boolean*): preserves memory by dumping the GAMS model instance representation

temporarily to disk ↩

In order to provide the maximum amount of memory to the solver this option dumps the internal representation of the model instance temporarily to disk and frees memory. This option only works with `SolveLink=0` and only for models without quadratic constraints for CplexD only.

Default: 0

gubcovers (*integer*): GUB cover cut generation ↩

Determines whether or not GUB (Generalized Upper Bound) cover cuts should be generated during optimization. The default of 0 indicates that the attempt to generate GUB cuts should continue only if it seems to be helping.

Default: 0

value	meaning
-1	Do not generate GUB cover cuts
0	Determined automatically
1	Generate GUB cover cuts moderately
2	Generate GUB cover cuts aggressively

heurfreq (*integer*): heuristic frequency ↩

This option specifies how often to apply the node heuristic. Setting to a positive number applies the heuristic at the requested node interval.

Default: 0

value	meaning
-1	Do not use the node heuristic
0	Determined automatically

iis (*boolean*): run the conflict refiner also known as IIS finder if the problem is infeasible ↩

Find an set of conflicting constraints or IIS (Irreducibly Inconsistent Set) and write an conflict report to the GAMS solution listing if the model is found to be infeasible.

Default: 0

implbd (*integer*): implied bound cut generation ↩

Determines whether or not implied bound cuts should be generated during optimization.

Default: 0

value	meaning
-1	Do not generate implied bound cuts
0	Determined automatically
1	Generate implied bound cuts moderately
2	Generate implied bound cuts aggressively

interactive (*boolean*): allow interactive option setting after a Control-C ↩

When set to yes, options can be set interactively after interrupting Cplex with a Control-C. Options are entered just as if they were being entered in the `cplex.opt` file. Control is returned to Cplex by entering `continue`. The optimization can be aborted by entering `abort`. This option can only be used when running from the command line. Moreover, the GAMS option `InteractiveSolver` needs to be set to 1.

Default: 0

intsollim (*integer*): maximum number of integer solutions ↩

This option limits the MIP optimization to finding only this number of mixed integer solutions before stopping.

Default: **large**

itlim (*integer*): iteration limit ↩

Synonym: `iterlim`

The iteration limit option sets the maximum number of iterations before the algorithm terminates, without reaching optimality. This Cplex option overrides the GAMS `IterLim` option. Any non-negative integer value is valid.

Default: **GAMS IterLim**

lbheur (*boolean*): local branching heuristic ↩

This parameter lets you control whether Cplex applies a local branching heuristic to try to improve new incumbents found during a MIP search. By default, this parameter is off. If you turn it on, Cplex will invoke a local branching heuristic only when it finds a new incumbent. If Cplex finds multiple incumbents at a single node, the local branching heuristic will be applied only to the last one found.

Default: 0

value	meaning
0	Off
1	Apply local branching heuristic to new incumbent

liftprojcuts (*integer*): lift-and-project cuts ↩

Default: 0

value	meaning
-1	Do not generate lift-and-project cuts
0	Determined automatically
1	Generate lift-and-project cuts moderately
2	Generate lift-and-project cuts aggressively
3	Generate lift-and-project cuts very aggressively

localimplied (*integer*): generation of locally valid implied bound cuts ↩

Default: 0

value	meaning
-1	Do not generate locally valid implied bound cuts
0	Determined automatically
1	Generate locally valid implied bound cuts moderately
2	Generate locally valid implied bound cuts aggressively
3	Generate locally valid implied bound cuts very aggressively

lpmethod (*integer*): algorithm to be used for LP problems ↔

Specifies which LP algorithm to use. If left at the default value (0 for automatic), and a primal-feasible basis is available, primal simplex will be used. If no primal-feasible basis is available, and **Threads** is equal to 1, dual simplex will be used. If **Threads** is greater than 1 and no primal-feasible basis is available, the concurrent option will be used.

Sifting may be useful for problems with many more variables than equations.

The concurrent option runs multiple methods in parallel. The first thread uses dual simplex. The second thread uses barrier. The next thread uses primal simplex. Remaining threads are used by the barrier run. If the aspect ratio (number of columns versus number of rows) is large, and if more than 10 threads are available, then concurrent optimization also invokes sifting on the LP. The solution is returned by first method to finish.

Default: 0

value	meaning
0	Automatic
1	Primal Simplex
2	Dual Simplex
3	Network Simplex
4	Barrier
5	Sifting
6	Concurrent

mfcuts (*integer*): multi-commodity flow cut generation ↔

Specifies whether Cplex should generate multi-commodity flow (MCF) cuts in a problem where Cplex detects the characteristics of a multi-commodity flow network with arc capacities. By default, Cplex decides whether or not to generate such cuts. To turn off generation of such cuts, set this parameter to -1. Cplex is able to recognize the structure of a network as represented in many real-world models. When it recognizes such a network structure, Cplex is able to generate cutting planes that usually help solve such problems. In this case, the cuts that Cplex generates state that the capacities installed on arcs pointing into a component of the network must be at least as large as the total flow demand of the component that cannot be satisfied by flow sources within the component.

Default: 0

value	meaning
-1	Do not generate MCF cuts
0	Determined automatically
1	Generate MCF cuts moderately
2	Generate MCF cuts aggressively

memoryemphasis (*boolean*): reduces use of memory ↔

This parameter lets you indicate to Cplex that it should conserve memory where possible. When you set this parameter to its non default value, Cplex will choose tactics, such as data compression or disk storage, for some of the data computed by the barrier and MIP optimizers. Of course, conserving memory may impact performance in some models. Also, while solution information will be available after optimization, certain computations that require a basis that has been factored (for example, for the computation of the condition number Kappa) may be unavailable.

Default: 0

value	meaning
0	Do not conserve memory
1	Conserve memory where possible

mipdisplay (*integer*): progress display level ↔

The amount of information displayed during MIP solution increases with increasing values of this option.

Default: 4

value	meaning
0	No display
1	Display integer feasible solutions
2	Displays nodes under mipinterval control
3	Same as 2 but adds information on cuts
4	Same as 3 but adds LP display for the root node
5	Same as 3 but adds LP display for all nodes

mipemphasis (*integer*): MIP solution tactics ↔

This option controls the tactics for solving a mixed integer programming problem.

Default: 0

value	meaning
0	Balance optimality and feasibility
1	Emphasize feasibility over optimality
2	Emphasize optimality over feasibility
3	Emphasize moving the best bound
4	Emphasize hidden feasible solutions

mipinterval (*integer*): progress display interval ↔

Controls the frequency of node logging when the parameter [MIPDisplay](#) is set higher than 1 (one). Frequency must be an integer; it may be 0 (zero), positive, or negative. By default, CPLEX displays new information in the node log during a MIP solve at relatively high frequency during the early stages of solving a MIP model, and adds lines to the log at progressively longer intervals as solving continues. In other words, CPLEX logs information frequently in

the beginning and progressively less often as it works. When the value is a positive integer n , CPLEX displays new incumbents, plus it displays a new line in the log every n nodes. When the value is a negative integer n , CPLEX displays new incumbents, and the negative value determines how much processing CPLEX does before it displays a new line in the node log. A negative value close to zero means that CPLEX displays new lines in the log frequently. A negative value far from zero means that CPLEX displays new lines in the log less frequently. In other words, a negative value of this parameter contracts or dilates the interval at which CPLEX displays information in the node log.

Default: 0

mipkappastats (*integer*): MIP kappa computation ↩

MIP kappa summarizes the distribution of the condition number of the optimal bases CPLEX encountered during the solution of a MIP model. That summary may let you know more about the numerical difficulties of your MIP model. Because MIP kappa (as a statistical distribution) requires CPLEX to compute the condition number of the optimal bases of the subproblems during branch-and-cut search, you can compute the MIP kappa only when CPLEX solves the subproblem with its simplex optimizer. In other words, in order to obtain results with this parameter, you can not use the sifting optimizer nor the barrier without crossover to solve the subproblems. See the parameters [StartAlg](#) and [SubAlg](#).

Computing the kappa of a subproblem has a cost. In fact, computing MIP kappa for the basis matrices can be computationally expensive and thus generally slows down the solution of a problem. Therefore, the setting 0 (automatic) tells CPLEX generally not to compute MIP kappa, but in cases where the parameter [NumericalEmphasis](#) is turned on, CPLEX computes MIP kappa for a sample of subproblems. The value 1 (sample) leads to a negligible performance degradation on average, but can slow down the branch-and-cut exploration by as much as 10% on certain models. The value 2 (full) leads to a 2% performance degradation on average, but can significantly slow the branch-and-cut exploration on certain models. In practice, the value 1 (sample) is a good trade-off between performance and accuracy of statistics. If you need very accurate statistics, then use value 2 (full).

In case CPLEX is instructed to compute a MIP kappa distribution, the parameter [Quality](#) is automatically turned on.

Default: -1

value	meaning
-1	No MIP kappa statistics; default
0	Automatic: let CPLEX decide
1	Compute MIP kappa for a sample of subproblems
2	Compute MIP kappa for all subproblems

mipordind (*boolean*): priority list on/off ↩

Synonym: prioropt

Use priorities. Priorities should be assigned based on your knowledge of the problem. Variables with higher priorities will be branched upon before variables of lower priorities. This direction of the tree search can often dramatically reduce the number of nodes searched. For example, consider a problem with a binary variable representing a yes/no decision to build a factory, and other binary variables representing equipment selections within that factory. You would naturally want to explore whether or not the factory should be built before considering what specific equipment to purchased within the factory. By assigning a higher priority to the build/no build decision variable, you can force this logic into the tree search and eliminate

wasted computation time exploring uninteresting portions of the tree. When set at 0 (default), the `MIPOrdInd` option instructs Cplex not to use priorities for branching. When set to 1, priority orders are utilized.

Note: Priorities are assigned to discrete variables using the `.prior` suffix in the GAMS model. Lower `.prior` values mean higher priority. The `.prioropt` model suffix has to be used to signal GAMS to export the priorities to the solver.

Default: `GAMS PriorOpt`

value	meaning
0	Do not use priorities for branching
1	Priority orders are utilized

mipordtype (*integer*): priority order generation ↩

This option is used to select the type of generic priority order to generate when no priority order is present.

Default: 0

value	meaning
0	None
1	decreasing cost magnitude
2	increasing bound range
3	increasing cost per coefficient count

mipsearch (*integer*): search strategy for mixed integer programs ↩

Sets the search strategy for a mixed integer program. By default, Cplex chooses whether to apply dynamic search or conventional branch and cut based on characteristics of the model.

Default: 0

value	meaning
0	Automatic
1	Apply traditional branch and cut strategy
2	Apply dynamic search

mipstart (*integer*): use mip starting values ↩

This option controls the use of advanced starting values for mixed integer programs. A setting of 1 indicates that the values should be checked to see if they provide an integer feasible solution before starting optimization.

Default: 0

value	meaning
0	do not use the values
1	set discrete variable values and use auto mipstart level
2	set all variable values and use check feasibility mipstart level

value	meaning
3	set discrete variable values and use solve fixed mipstart level
4	set discrete variable values and use solve sub-MIP mipstart level
5	set discrete variable values and use solve repair-MIP mipstart level
6	set discrete variable values and use no checks at all

miptrace (*string*): filename of MIP trace file ↔

More info is available in chapter [Solve trace](#)

miptracenode (*integer*): node interval when a trace record is written ↔

More info is available in chapter [Solve trace](#)

Default: 100

miptracetime (*real*): time interval when a trace record is written ↔

More info is available in chapter [Solve trace](#)

Default: 1

miqcpstrat (*integer*): MIQCP relaxation choice ↔

This option controls how MIQCPs are solved. For some models, the setting 2 may be more effective than 1. You may need to experiment with this parameter to determine the best setting for your model.

Default: 0

value	meaning
0	Automatic
1	QCP relaxation Cplex will solve a QCP relaxation of the model at each node.
2	LP relaxation Cplex will solve a LP relaxation of the model at each node.

mircuts (*integer*): mixed integer rounding cut generation ↔

Determines whether or not to generate mixed integer rounding (MIR) cuts during optimization. At the default of 0, generation is continued only if it seems to be helping.

Default: 0

value	meaning
-1	Do not generate MIR cuts
0	Determined automatically
1	Generate MIR cuts moderately
2	Generate MIR cuts aggressively

mpslongnum (*boolean*): MPS file format precision of numeric output ↔

Determines the precision of numeric output in the MPS file formats. When this parameter is set to its default value 1 (one), numbers are written to MPS files in full-precision; that is, up to 15 significant digits may be written. The setting 0 (zero) writes files that correspond to the standard MPS format, where at most 12 characters can be used to represent a value. This limit may result in loss of precision.

Default: 1

value	meaning
0	Use limited MPS precision
1	Use full-precision

multobj (*boolean*): controls the hierarchical optimization of multiple objectives ↔

Default: 0

multobjdisplay (*integer*): level of display during multiobjective optimization ↔

Default: 1

value	meaning
0	No display
1	Summary display after each subproblem
2	Summary display after each subproblem, as well as subproblem logs

multobjmethod (*integer*): method used for multi-objective solves ↔

When solving a continuous multi-objective model using a hierarchical approach, the model is solved once for each objective. The algorithm used to solve for the highest priority objective is controlled by the [LPMethod](#) parameter. This parameter determines the algorithm used to solve for subsequent objectives.

Default: 0

names (*boolean*): load GAMS names into Cplex ↔

This option causes GAMS names for the variables and equations to be loaded into Cplex. These names will then be used for error messages, log entries, and so forth. Setting names to no may help if memory is very tight.

Default: 1

netdisplay (*integer*): network display level ↔

This option controls the log for network iterations.

Default: 2

value	meaning
0	No network log.
1	Displays true objective values
2	Displays penalized objective values

netepopt (*real*): optimality tolerance for the network simplex method ↩

This optimality tolerance influences the reduced-cost tolerance for optimality when using the network simplex method. This option setting governs how closely Cplex must approach the theoretically optimal solution.

Range: [1e-011, 0.1]

Default: 1e-006

neteprhs (*real*): feasibility tolerance for the network simplex method ↩

This feasibility tolerance determines the degree to which the network simplex algorithm will allow a flow value to violate its bounds.

Range: [1e-011, 0.1]

Default: 1e-006

netfind (*integer*): attempt network extraction ↩

Specifies the level of network extraction to be done.

Default: 2

value	meaning
1	Extract pure network only
2	Try reflection scaling
3	Try general scaling

netitlim (*integer*): iteration limit for network simplex ↩

Iteration limit for the network simplex method.

Default: large

netppriind (*integer*): network simplex pricing ↩

Network simplex pricing algorithm. The default of 0 (currently equivalent to 3) shows best performance for most problems.

Default: 0

value	meaning
0	Automatic
1	Partial pricing
2	Multiple partial pricing
3	Multiple partial pricing with sorting

nodefileind (*integer*): node storage file indicator ↩

Specifies how node files are handled during MIP processing. Used when parameter [WorkMem](#) has been exceeded by the size of the branch and cut tree. If set to 0 when the tree memory

limit is reached, optimization is terminated. Otherwise a group of nodes is removed from the in-memory set as needed. By default, Cplex transfers nodes to node files when the in-memory set is larger than 128 MBytes, and it keeps the resulting node *files* in compressed form in memory. At settings 2 and 3, the node files are transferred to disk. They are stored under a directory specified by parameter [WorkDir](#) and Cplex actively manages which nodes remain in memory for processing.

Default: 1

value	meaning
0	No node files
1	Node files in memory and compressed
2	Node files on disk
3	Node files on disk and compressed

nodelim (*integer*): maximum number of nodes to solve [↔](#)

Synonym: nodlim

The maximum number of nodes solved before the algorithm terminates, without reaching optimality. This option overrides the GAMS NodLim model suffix. When this parameter is set to 0 (this is only possible through an option file), Cplex completes processing at the root; that is, it creates cuts and applies heuristics at the root. When this parameter is set to 1 (one), it allows branching from the root; that is, nodes are created but not solved.

Default: GAMS NodLim

nodesel (*integer*): node selection strategy [↔](#)

This option is used to set the rule for selecting the next node to process when backtracking.

Default: 1

value	meaning
0	Depth-first search This chooses the most recently created node.
1	Best-bound search This chooses the unprocessed node with the best objective function for the associated LP relaxation.
2	Best-estimate search This chooses the node with the best estimate of the integer objective value that would be obtained once all integer infeasibilities are removed.
3	Alternate best-estimate search

numeralemphasis (*boolean*): emphasizes precision in numerically unstable or difficult problems [↔](#)

This parameter lets you indicate to Cplex that it should emphasize precision in numerically difficult or unstable problems, with consequent performance trade-offs in time and memory.

Default: 0

value	meaning
0	Off
1	Exercise extreme caution in computation

objdif (*real*): overrides GAMS Cheat parameter ↩

Synonym: cheat

A means for automatically updating the cutoff to more restrictive values. Normally the most recently found integer feasible solution objective value is used as the cutoff for subsequent nodes. When this option is set to a positive value, the value will be subtracted from (added to) the newly found integer objective value when minimizing (maximizing). This forces the MIP optimization to ignore integer solutions that are not at least this amount better than the one found so far. The option can be adjusted to improve problem solving efficiency by limiting the number of nodes; however, setting this option at a value other than zero (the default) can cause some integer solutions, including the true integer optimum, to be missed. Negative values for this option will result in some integer solutions that are worse than or the same as those previously generated, but will not necessarily result in the generation of all possible integer solutions. This option overrides the GAMS Cheat parameter.

Default: 0

objllim (*real*): objective function lower limit ↩

Setting a lower objective function limit will cause Cplex to halt the optimization process once the minimum objective function value limit has been exceeded.

Default: -1e+075

objnabstol (*string*): allowable absolute degradation for objective ↩

This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization ([MultObj](#)). The syntax for this parameter is `ObjNAbsTo1 ObjVarName value`.

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. If it achieves objective value z when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most `ObjNAbsTo1`.

objnreitol (*string*): allowable relative degradation for objective ↩

This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization ([MultObj](#)). The syntax for this parameter is `ObjNRelTo1 ObjVarName value`.

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. If it achieves objective value z when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most `ObjNRelTo1*|z|`.

objrng (*string*): do objective ranging ↩

Calculate sensitivity ranges for the specified GAMS variables. Unlike most options, `ObjRng` can be repeated multiple times in the options file. Sensitivity range information will be produced for each GAMS variable named. Specifying `all` will cause range information to be produced for all variables. Range information will be printed to the beginning of the solution listing in the GAMS listing file unless option [RngRestart](#) is specified.

Default: no objective ranging is done

objulim (*real*): objective function upper limit ↩

Setting an upper objective function limit will cause Cplex to halt the optimization process once the maximum objective function value limit has been exceeded.

Default: 1e+075

optimalitytarget (*integer*): type of optimality that Cplex targets ↔

This parameter specifies the type of solution that CPLEX attempts to compute with respect to the optimality of that solution when CPLEX solves a continuous (QP) or mixed integer (MIQP) quadratic model. In other words, the variables of the model can be continuous or mixed integer and continuous; the objective function includes a quadratic term, and perhaps the objective function is not positive semi-definite (non PSD). This parameter does not apply to quadratically constrained mixed integer problems (MIQCP); that is, this parameter does not apply to mixed integer problems that include a quadratic term among the constraints.

Default: 0

value	meaning
0	Automatic CPLEX first attempts to compute a provably optimal solution. If CPLEX cannot compute a provably optimal solution because the objective function is not convex, CPLEX will return with an error (Q is not PSD).
1	Search for a globally optimal solution to a convex model CPLEX searches for a globally optimal solution to a convex model. In problems of type QP or MIQP, this setting interacts with linearization switch QToLin for QP, MIQP
2	Search for a solution that satisfies first-order optimality conditions no optimality guarantee CPLEX first attempt to compute a provably optimal solution. If CPLEX cannot compute a provably optimal solution because the objective function is not convex, CPLEX searches for a solution that satisfies first-order optimality conditions but is not necessarily globally optimal.
3	Search for a globally optimal solution regardless of convexity If the problem type is QP, CPLEX first changes the problem type to MIQP. CPLEX then solves the problem (whether originally QP or MIQP) to global optimality. In problems of type QP or MIQP, this setting interacts with with linearization switch QToLin for QP, MIQP. With this setting information about dual values is not available for the solution.

parallelmode (*integer*): parallel optimization mode ↔

Sets the parallel optimization mode. Possible modes are automatic, deterministic, and opportunistic.

In this context, deterministic means that multiple runs with the same model at the same parameter settings on the same platform will reproduce the same solution path and results. In contrast, opportunistic implies that even slight differences in timing among threads or in the order in which tasks are executed in different threads may produce a different solution path and consequently different timings or different solution vectors during optimization executed in parallel threads. When running with multiple threads, the opportunistic setting entails less synchronization between threads and consequently may provide better performance.

In deterministic mode, Cplex applies as much parallelism as possible while still achieving deterministic results. That is, when you run the same model twice on the same platform with the same parameter settings, you will see the same solution and optimization run.

More opportunities to exploit parallelism are available if you do not require determinism. In other words, Cplex can find more opportunities for parallelism if you do not require an invariant, repeatable solution path and precisely the same solution vector. To use all available parallelism, you need to select the opportunistic parallel mode. In this mode, Cplex will utilize all opportunities for parallelism in order to achieve best performance.

However, in opportunistic mode, the actual optimization may differ from run to run, including the solution time itself. A truly parallel deterministic algorithm is available only for MIP optimization. Only opportunistic parallel algorithms (barrier and concurrent optimizers) are available for continuous models. (Each of the simplex algorithms runs sequentially on a continuous model.) Consequently, when parallel mode is set to deterministic, both barrier and concurrent optimizers are restricted to run only sequentially, not in parallel.

A GAMS/Cplex run will use deterministic mode unless explicitly specified.

If **ParallelMode** is explicitly set to 0 (automatic) the settings of this parallel mode parameter interact with settings of the **Threads** parameter. Let the result number of threads available to Cplex be n (note that negative values for the threads parameter are possible to exclude work on some cores).

$n=0$: Cplex uses maximum number of threads (determined by the computing platform) in deterministic mode unless **ParallelMode** is set to -1 (opportunistic).

$n=1$: Cplex runs sequential.

$n>1$: Cplex uses maximum number of threads (determined by the computing platform) in opportunistic mode unless **ParallelMode** is set to 1 (deterministic).

Here is list of possible value:

Default: 1

value	meaning
-1	Enable opportunistic parallel search mode
0	Automatic
1	Enable deterministic parallel search mode

perind (*boolean*): force initial perturbation ↩

Perturbation Indicator. If a problem automatically perturbs early in the solution process, consider starting the solution process with a perturbation by setting **PerInd** to 1. Manually perturbing the problem will save the time of first allowing the optimization to stall before activating the perturbation mechanism, but is useful only rarely, for extremely degenerate problems.

Default: 0

value	meaning
0	not automatically perturbed
1	automatically perturbed

perlim (*integer*): number of stalled iterations before perturbation ↩

Perturbation limit. The number of stalled iterations before perturbation is invoked. The default value of 0 means the number is determined automatically.

Default: 0

polishafterdetime (*real*): deterministic time before starting to polish a feasible solution [↔](#)

Default: 1e+075

polishafterepagap (*real*): absolute MIP gap before starting to polish a feasible solution [↔](#)

Solution polishing can yield better solutions in situations where good solutions are otherwise hard to find. More time-intensive than other heuristics, solution polishing is actually a variety of branch-and-cut that works after an initial solution is available. In fact, it requires a solution to be available for polishing, either a solution produced by branch-and-cut, or a MIP start supplied by a user. Because of the high cost entailed by solution polishing, it is not called throughout branch-and-cut like other heuristics. Instead, solution polishing works in a second phase after a first phase of conventional branch-and-cut. As an additional step after branch-and-cut, solution polishing can improve the best known solution. As a kind of branch-and-cut algorithm itself, solution polishing focuses solely on finding better solutions. Consequently, it may not prove optimality, even if the optimal solution has indeed been found. Like the RINS heuristic, solution polishing explores neighborhoods of previously found solutions by solving subMIPs.

Sets an absolute MIP gap (that is, the difference between the best integer objective and the objective of the best node remaining) after which CPLEX stops branch-and-cut and begins polishing a feasible solution. The default value is such that CPLEX does not invoke solution polishing by default.

Default: 0

polishafterepgap (*real*): relative MIP gap before starting to polish a solution [↔](#)

Sets a relative MIP gap after which CPLEX will stop branch-and-cut and begin polishing a feasible solution. The default value is such that CPLEX does not invoke solution polishing by default.

Default: 0

polishafterintsol (*integer*): MIP integer solutions to find before starting to polish a feasible solution [↔](#)

Sets the number of integer solutions to find before CPLEX stops branch-and-cut and begins to polish a feasible solution. The default value is such that CPLEX does not invoke solution polishing by default.

Default: 2100000000

polishafternode (*integer*): nodes to process before starting to polish a feasible solution [↔](#)

Sets the number of nodes processed in branch-and-cut before CPLEX starts solution polishing, if a feasible solution is available.

Default: 2100000000

polishaftertime (*real*): time before starting to polish a feasible solution [↔](#)

Tells CPLEX how much time in seconds to spend during mixed integer optimization before CPLEX starts polishing a feasible solution. The default value is such that CPLEX does not start solution polishing by default.

Default: 1e+075

populatelim (*integer*): limit of solutions generated for the solution pool by populate method ↩

Limits the number of solutions generated for the solution pool during each call to the populate procedure. Populate stops when it has generated *PopulateLim* solutions. A solution is counted if it is valid for all filters (see [DivFlt](#) and consistent with the relative and absolute pool gap parameters (see [SolnPoolGap](#) and [SolnPoolAGap](#)), and has not been rejected by the incumbent checking routine (see [UserIncBCall](#)), whether or not it improves the objective of the model. This parameter does not apply to MIP optimization generally; it applies only to the populate procedure.

If you are looking for a parameter to control the number of solutions stored in the solution pool, consider the parameter [SolnPoolCapacity](#) instead.

Populate will stop before it reaches the limit set by this parameter if it reaches another limit, such as a time or node limit set by the user.

Default: 20

ppriind (*integer*): primal simplex pricing ↩

Pricing algorithm. Likely to show the biggest impact on performance. Look at overall solution time and the number of Phase I and total iterations as a guide in selecting alternate pricing algorithms. If you are using the dual Simplex method use [DPriInd](#) to select a pricing algorithm. If the number of iterations required to solve your problem is approximately the same as the number of rows in your problem, then you are doing well. Iteration counts more than three times greater than the number of rows suggest that improvements might be possible.

Default: 0

value	meaning
-1	Reduced-cost pricing This is less compute intensive and may be preferred if the problem is small or easy. This option may also be advantageous for dense problems (say 20 to 30 nonzeros per column).
0	Hybrid reduced-cost and Devex pricing
1	Devex pricing This may be useful for more difficult problems which take many iterations to complete Phase I. Each iteration may consume more time, but the reduced number of total iterations may lead to an overall reduction in time. Tenfold iteration count reductions leading to threefold speed improvements have been observed. Do not use devex pricing if the problem has many columns and relatively few rows. The number of calculations required per iteration will usually be disadvantageous.
2	Steepest edge pricing If devex pricing helps, this option may be beneficial. Steepest-edge pricing is computationally expensive, but may produce the best results on exceptionally difficult problems.
3	Steepest edge pricing with slack initial norms This reduces the computationally intensive nature of steepest edge pricing.
4	Full pricing

predual (*integer*): give dual problem to the optimizer ↩

Solve the dual. Some linear programs with many more rows than columns may be solved faster by explicitly solving the dual. The **PreDual** option will cause Cplex to solve the dual while returning the solution in the context of the original problem. This option is ignored if presolve is turned off.

Default: 0

value	meaning
-1	do not give dual to optimizer
0	automatic
1	give dual to optimizer

preind (*boolean*): turn presolver on/off ↩

Perform Presolve. This helps most problems by simplifying, reducing and eliminating redundancies. However, if there are no redundancies or opportunities for simplification in the model, it may be faster to turn presolve off to avoid this step. On rare occasions, the presolved model, although smaller, may be more difficult than the original problem. In this case turning the presolve off leads to better performance. Specifying 0 turns the aggregator off as well.

Default: 1

prelinear (*boolean*): linear reduction indicator ↩

If only linear reductions are performed, each variable in the original model can be expressed as a linear form of variables in the presolved model.

Default: 1

prepass (*integer*): number of presolve applications to perform ↩

Number of MIP presolve applications to perform. By default, Cplex determines this automatically. Specifying 0 turns off the presolve but not the aggregator. Set **PreInd** to 0 to turn both off.

Default: -1

value	meaning
-1	Determined automatically
0	No presolve
>0	Number of MIP presolve applications to perform

preslvnd (*integer*): node presolve selector ↩

Indicates whether node presolve should be performed at the nodes of a mixed integer programming solution. Node presolve can significantly reduce solution time for some models. The default setting is generally effective.

Default: 0

value	meaning
-1	No node presolve
0	Automatic
1	Force node presolve
2	Perform probing on integer-infeasible variables

pricelim (*integer*): pricing candidate list ↩

Size for the pricing candidate list. Cplex dynamically determines a good value based on problem dimensions. Only very rarely will setting this option manually improve performance. Any non-negative integer values are valid.

Default: 0, in which case it is determined automatically

printoptions (*boolean*): list values of all options to GAMS listing file [↔](#)

Write the values of all options to the GAMS listing file. Valid values are no or yes.

Default: 0

probe (*integer*): perform probing before solving a MIP [↔](#)

Determines the amount of probing performed on a MIP. Probing can be both very powerful and very time consuming. Setting the value to 1 can result in dramatic reductions or dramatic increases in solution time depending on the particular model.

Default: 0

value	meaning
-1	No probing
0	Automatic
1	Limited probing
2	More probing
3	Full probing

probedetime (*real*): deterministic time spent probing [↔](#)

Default: 1e+075

probetime (*real*): time spent probing [↔](#)

Limits the amount of time in seconds spent probing.

Default: 1e+075

qpmakepsdind (*boolean*): adjust MIQP formulation to make the quadratic matrix positive-semi-definite [↔](#)

Determines whether Cplex will attempt to adjust a MIQP formulation, in which all the variables appearing in the quadratic term are binary. When this feature is active, adjustments will be made to the elements of a quadratic matrix that is not nominally positive semi-definite (*PSD*, as required by Cplex for all QP formulations), to make it PSD, and will also attempt to tighten an already PSD matrix for better numerical behavior. The default setting of 1 means **yes** but you can turn it off if necessary; most models should benefit from the default setting.

Default: 1

value	meaning
0	Off
1	On

qpmethod (*integer*): algorithm to be used for QP problems [↔](#)

Specifies which QP algorithm to use.

At the default of 0 (automatic), barrier is used for QP problems and dual simplex for the root relaxation of MIQP problems.

Default: 0

value	meaning
0	Automatic
1	Primal Simplex
2	Dual Simplex
3	Network Simplex
4	Barrier
5	Sifting
6	Concurrent dual, barrier, and primal

qtolin (*integer*): linearization of the quadratic terms in the objective function of a QP or MIQP model ↔

This parameter switches on or off linearization of the quadratic terms in the objective function of a quadratic program or of a mixed integer quadratic program.

In a convex mixed integer quadratic program, this parameter controls whether Cplex linearizes the product of binary variables in the objective function during presolve. In a nonconvex quadratic program or mixed integer quadratic program solved to global optimality according to [OptimalityTarget](#), this parameter controls how Cplex linearizes the product of bounded variables in the objective function during presolve.

This parameter interacts with the existing parameter [OptimalityTarget](#): When the solution target type is set to 1 (that is, Cplex searches for a globally optimal solution to a convex model), then in a convex MIQP, this parameter tells Cplex to replace the product of a binary variable and a bounded linear variable by a linearly constrained variable. When the solution target type is set to 3, then in a nonconvex QP or nonconvex MIQP, this parameter controls the initial relaxation.

Default: -1

value	meaning
-1	Automatic
0	Off, Cplex does not linearize quadratic terms in the objective
1	On, Cplex linearizes quadratic terms in the objective

quality (*boolean*): write solution quality statistics ↔

Write solution quality statistics to the listing and log file. If set to yes, the statistics appear after the Solve Summary and before the Solution Listing and contain information about infeasibility levels, solution value magnituded, and the condition number (kappa):

Solution Quality Statistics:

	unscaled		scaled	
	max	sum	max	sum
primal infeasibility	0.000e+00	0.000e+00	0.000e+00	0.000e+00
dual infeasibility	0.000e+00	0.000e+00	0.000e+00	0.000e+00
primal residual	0.000e+00	0.000e+00	0.000e+00	0.000e+00
dual residual	0.000e+00	0.000e+00	0.000e+00	0.000e+00

primal solution vector	3.000e+02	9.000e+02	3.000e+02	9.000e+02
dual solution vector	1.000e+00	1.504e+00	1.000e+00	1.504e+00
slacks	5.000e+01	5.000e+01	5.000e+01	5.000e+01
reduced costs	3.600e-02	4.500e-02	3.600e-02	4.500e-02

Condition number of the scaled basis matrix = 9.000e+00

Default: 0

rampupdetlimit (*real*): limits the amount of time in deterministic ticks spent during ramp up of distributed parallel optimization ↔

This parameter specifies a limit on the amount of time measured in deterministic ticks to spend in the ramp up phase of distributed parallel optimization. This parameter is effective only when the ramp up duration parameter has a value of 0 (zero) or 1 (one), where 0 (zero) designates the default automatic value that CPLEX decides the ramp up duration, and 1 (one) designates dynamic ramp up. See ramp up duration for more detail about the conditions for time limits in ramp up.

The value 0 (zero) specifies that no time should be spent in ramp up.

Any positive number strictly greater than zero specifies a time limit in deterministic ticks.

Default: 1e+075

rampupduration (*integer*): customizes ramp up for distributed parallel optimization ↔

During the ramp up phase of distributed parallel optimization, each worker applies different parameter settings to the same problem as the other workers. In other words, there is a competition among the workers to process the greatest number of nodes in parallel in the search tree of the distributed problem. At any given time, each worker is a candidate to be the winner of this competition.

This parameter enables you to customize the ramp up phase for your model. Its value has an impact on both timing parameters: time spent in ramp up during distributed parallel optimization and deterministic time spent in ramp up during distributed parallel optimization.

When the value of this parameter is -1, CPLEX turns off ramp up and ignores both of the parameters time spent in ramp up during distributed parallel optimization and deterministic time spent in ramp up during distributed parallel optimization. CPLEX directly begins distributed parallel tree search.

When the value of this parameter is 2, CPLEX observes ramp up with an infinite horizon. CPLEX ignores both of the parameters time spent in ramp up during distributed parallel optimization and deterministic time spent in ramp up during distributed parallel optimization. CPLEX never switches to distributed parallel tree search. This situation is also known as concurrent mixed integer programming (concurrent MIP).

When the value of this parameter is 1 (one), CPLEX considers the values of both time spent in ramp up during distributed parallel optimization and deterministic time spent in ramp up during distributed parallel optimization.

- If both ramp up timing parameters are at their default value (effectively, an infinite amount of time), then CPLEX terminates ramp up according to internal criteria before switching to distributed parallel tree search.
- If one or both of the ramp up timing parameters is set to a non default finite value, CPLEX observes that time limit by executing ramp up for that given amount of time. If the two time limits differ, CPLEX observes the smaller time limit before terminating ramp up and switching to distributed parallel tree search.

When the value of this parameter remains at its default, 0 (zero), CPLEX considers the values of both timing parameters time spent in ramp up during distributed parallel optimization and deterministic time spent in ramp up during distributed parallel optimization.

- If at least one of the ramp up timing parameters is set to a finite value, then CPLEX behaves as it does when the value of this parameter is 1 (one): first ramping up, then switching to distributed parallel tree search.
- If both of the ramp up timing parameters are at their default value (effectively an infinite amount of time), then CPLEX behaves as it does when the value of this parameter is 2: concurrent MIP.

Default: 0

value	meaning
-1	Turns off ramp up
0	Automatic
1	Dynamically switch to distributed tree search
2	Infinite horizon for ramp up AKA concurrent MIP optimization

rampuptimelimit (*real*): limits the amount of time in seconds spent during ramp up of distributed parallel optimization ↩

This parameters specifies a limit on the amount of time in seconds to spend in the ramp up phase of distributed parallel optimization. This parameter is effective only when the ramp up duration parameter has a value of 0 (zero) or 1 (one), where 0 (zero) designates the default automatic value that CPLEX decides the ramp up duration, and 1 (one) designates dynamic ramp up. See ramp up duration for more detail about the conditions for time limits in ramp up.

The value 0 (zero) specifies that no time should be spent in ramp up.

Any positive number strictly greater than zero specifies a time limit in seconds.

Default: 1e+075

randomseed (*integer*): sets the random seed differently for diversity of solutions ↩

Default: changes with each Cplex release

readfit (*string*): reads Cplex solution pool filter file ↩

The GAMS/Cplex solution pool options cover the basic use of diversity and range filters for producing multiple solutions. If you need multiple filters, weights on diversity filters or other advanced uses of solution pool filters, you could produce a Cplex filter file with your favorite editor or the GAMS Put Facility and read this into GAMS/Cplex using this option.

reduce (*integer*): primal and dual reduction type ↩

Determines whether primal reductions, dual reductions, or both, are performed during preprocessing. It is occasionally advisable to do only one or the other when diagnosing infeasible or unbounded models.

Default: 3

value	meaning
0	No primal or dual reductions
1	Only primal reductions
2	Only dual reductions
3	Both primal and dual reductions

reinv (*integer*): refactorization frequency ↔

Refactorization Frequency. This option determines the number of iterations between refactorizations of the basis matrix. The default should be optimal for most problems. Cplex's performance is relatively insensitive to changes in refactorization frequency. Only for extremely large, difficult problems should reducing the number of iterations between refactorizations be considered. Any non-negative integer value is valid.

Default: 0, in which case it is determined automatically

relaxfixedinfeas (*boolean*): accept small infeasibilities in the solve of the fixed problem ↔

Sometimes the solution of the fixed problem of a MIP does not solve to optimality due to small (dual) infeasibilities. The default behavior of the GAMS/Cplex link is to return the primal solution values only. If the option is set to 1, the small infeasibilities are ignored and a full solution including the dual values are reported back to GAMS.

Default: 0

value	meaning
0	Off
1	On

relaxpreind (*integer*): presolve for initial relaxation on/off ↔

This option will cause the Cplex presolve to be invoked for the initial relaxation of a mixed integer program (according to the other presolve option settings). Sometimes, additional reductions can be made beyond any MIP presolve reductions that may already have been done.

Default: -1

value	meaning
-1	Automatic
0	do not presolve initial relaxation
1	use presolve on initial relaxation

relobjdif (*real*): relative cheat parameter ↔

The relative version of the **ObjDif** option. Ignored if **ObjDif** is non-zero.

Default: 0

repairtries (*integer*): try to repair infeasible MIP start ↔

This parameter lets you indicate to Cplex whether and how many times it should try to repair an infeasible MIP start that you supplied. The parameter has no effect if the MIP start you supplied is feasible. It has no effect if no MIP start was supplied.

Default: 0

value	meaning
-1	None: do not try to repair
0	Automatic
>0	Maximum tries to perform

repeatpresolve (*integer*): reapply presolve at root after preprocessing ↩

This integer parameter tells Cplex whether to re-apply presolve, with or without cuts, to a MIP model after processing at the root is otherwise complete.

Default: -1

value	meaning
-1	Automatic
0	Turn off represolve
1	Represolve without cuts
2	Represolve with cuts
3	Represolve with cuts and allow new root cuts

rerun (*string*): rerun problem if presolve infeasible or unbounded ↩

The Cplex presolve can sometimes diagnose a problem as being infeasible or unbounded. When this happens, GAMS/Cplex can, in order to get better diagnostic information, rerun the problem with presolve turned off. The GAMS solution listing will then mark variables and equations as infeasible or unbounded according to the final solution returned by the simplex algorithm. The [IIS](#) option can be used to get even more diagnostic information. The rerun option controls this behavior. Valid values are **auto**, **yes**, **no** and **nono**. The value of **auto** is equivalent to **no** if names are successfully loaded into Cplex and option [IIS](#) is set to **no**. In that case the Cplex messages from presolve help identify the cause of infeasibility or unboundedness in terms of GAMS variable and equation names. If names are not successfully loaded, rerun defaults to **yes**. Loading of GAMS names into Cplex is controlled by option [Names](#). The value of **nono** only affects MIP models for which Cplex finds a feasible solution in the branch-and-bound tree but the fixed problem turns out to be infeasible. In this case the value **nono** also disables the rerun without presolve, while the value of **no** still tries this run. Feasible integer solution but an infeasible fixed problem happens in few cases and mostly with badly scaled models. If you experience this try more aggressive scaling ([ScaInd](#)) or tightening the integer feasibility tolerance [EPInt](#). If the fixed model is infeasible only the primal solution is returned to GAMS. You can recognize this inside GAMS by checking the marginal of the objective defining constraint which is always nonzero.

Default: **yes**

value	meaning
auto	Automatic
yes	Rerun infeasible models with presolve turned off
no	Do not rerun infeasible models
nono	Do not rerun infeasible fixed MIP models

rhsrng (*string*): do right-hand-side ranging ↩

Calculate sensitivity ranges for the specified GAMS equations. Unlike most options, **RHSRng** can be repeated multiple times in the options file. Sensitivity range information will be

produced for each GAMS equation named. Specifying **all** will cause range information to be produced for all equations. Range information will be printed to the beginning of the solution listing in the GAMS listing file unless option **RngRestart** is specified.

Default: **no right-hand-side ranging is done**

rinsheur (*integer*): relaxation induced neighborhood search frequency ↔

Cplex implements a heuristic known as Relaxation Induced Neighborhood Search (RINS) for MIP and MIQCP problems. RINS explores a neighborhood of the current incumbent to try to find a new, improved incumbent. It formulates the neighborhood exploration as a MIP, a subproblem known as the subMIP, and truncates the subMIP solution by limiting the number of nodes explored in the search tree.

Parameter **RINSHeur** controls how often RINS is invoked. A value of 100, for example, means that RINS is invoked every hundredth node in the tree.

Default: 0

value	meaning
-1	Disable RINS
0	Automatic

rngrestart (*string*): write GAMS readable ranging information file ↔

Write ranging information, in GAMS readable format, to the file named. Options **ObjRng** and **RHSRng** are used to specify which GAMS variables or equations are included.

Default: **ranging information is printed to the listing file**

rtlcuts (*integer*): Reformulation Linearization Technique (RLT) cuts ↔

This parameter controls the addition of cuts based on the Reformulation Linearization Technique (RLT) for nonconvex quadratic programs (QP) or mixed integer quadratic programs (MIQP) solved to global optimality. That is, the **OptimalityTarget** parameter must be set to 3. The **RTLCuts** option is not controlled by the option **Cuts**.

Default: 0

value	meaning
-1	Do not generate RTL cuts
0	Determined automatically
1	Generate RTL cuts moderately
2	Generate RTL cuts aggressively
3	Generate RTL cuts very aggressively

scaind (*integer*): matrix scaling on/off ↔

This option influences the scaling of the problem matrix.

Default: 0

value	meaning
-1	No scaling

value	meaning
0	Standard scaling An equilibration scaling method is implemented which is generally very effective.
1	Modified, more aggressive scaling method This method can produce improvements on some problems. This scaling should be used if the problem is observed to have difficulty staying feasible during the solution process.

siftalg (*integer*): sifting subproblem algorithm ↔

Sets the algorithm to be used for solving sifting subproblems.

Default: 0

value	meaning
0	Automatic
1	Primal simplex
2	Dual simplex
3	Network simplex
4	Barrier

siftdisplay (*integer*): sifting display level ↔

Determines the amount of sifting progress information to be displayed.

Default: 1

value	meaning
0	No display
1	Display major iterations
2	Display LP subproblem information

sifting (*boolean*): switch for sifting from simplex optimization ↔

Default: 1

siftitlim (*integer*): limit on sifting iterations ↔

Sets the maximum number of sifting iterations that may be performed if convergence to optimality has not been reached.

Default: **large**

simdisplay (*integer*): simplex display level ↔

This option controls what Cplex reports (normally to the screen) during optimization. The amount of information displayed increases as the setting value increases.

Default: 1

value	meaning
0	No iteration messages are issued until the optimal solution is reported

value	meaning
1	An iteration log message will be issued after each refactorization Each entry will contain the iteration count and scaled infeasibility or objective value.
2	An iteration log message will be issued after each iteration The variables, slacks and artificials entering and leaving the basis will also be reported.

singlim (*integer*): limit on singularity repairs ↩

The singularity limit setting restricts the number of times Cplex will attempt to repair the basis when singularities are encountered. Once the limit is exceeded, Cplex replaces the current basis with the best factorizable basis that has been found. Any non-negative integer value is valid.

Default: 10

solnpool (*string*): solution pool file name ↩

The solution pool enables you to generate and store multiple solutions to a MIP problem. The option expects a GDX filename. This GDX file name contains the information about the different solutions generated by Cplex. Inside your GAMS program you can process the GDX file and read the different solution point files. Please check the GAMS/Cplex solver guide document and the example model `solnpool.gms` from the GAMS model library.

solnpoolgap (*real*): absolute tolerance for the solutions in the solution pool ↩

Sets an absolute tolerance on the objective bound for the solutions in the solution pool. Solutions that are worse (either greater in the case of a minimization, or less in the case of a maximization) than the objective of the incumbent solution according to this measure are not kept in the solution pool.

Values of the solution pool absolute gap and the solution pool relative gap `SolnPoolGap` may differ: For example, you may specify that solutions must be within 15 units by means of the solution pool absolute gap and also within 1% of the incumbent by means of the solution pool relative gap. A solution is accepted in the pool only if it is valid for both the relative and the absolute gaps.

The solution pool absolute gap parameter can also be used as a stopping criterion for the populate procedure: if populate cannot enumerate any more solutions that satisfy this objective quality, then it will stop. In the presence of both an absolute and a relative solution pool gap parameter, populate will stop when the smaller of the two is reached.

Default: 1e+075

solnpoolcapacity (*integer*): limits of solutions kept in the solution pool ↩

Limits the number of solutions kept in the solution pool. At most, `SolnPoolCapacity` solutions will be stored in the pool. Superfluous solutions are managed according to the replacement strategy set by the solution pool replacement parameter `SolnPoolReplace`.

The optimization (whether by MIP optimization or the populate procedure) will not stop if more than `SolnPoolCapacity` are generated. Instead, stopping criteria are regular node and time limits and `PopulateLim`, `SolnPoolGap` and `SolnPoolAGap`.

Default: 2100000000

solnpoolgap (*real*): relative tolerance for the solutions in the solution pool ↩

Sets a relative tolerance on the objective bound for the solutions in the solution pool. Solutions that are worse (either greater in the case of a minimization, or less in the case of a maximization) than the incumbent solution by this measure are not kept in the solution pool.

Values of the solution pool absolute gap [SolnPoolAGap](#) and the solution pool relative gap may differ: For example, you may specify that solutions must be within 15 units by means of the solution pool absolute gap and within 1% of the incumbent by means of the solution pool relative gap. A solution is accepted in the pool only if it is valid for both the relative and the absolute gaps.

The solution pool relative gap parameter can also be used as a stopping criterion for the populate procedure: if populate cannot enumerate any more solutions that satisfy this objective quality, then it will stop. In the presence of both an absolute and a relative solution pool gap parameter, populate will stop when the smaller of the two is reached.

Default: 1e+075

solnpoolintensity (*integer*): solution pool intensity for ability to produce multiple solutions ↩

Controls the trade-off between the number of solutions generated for the solution pool and the amount of time or memory consumed. This parameter applies both to MIP optimization and to the populate procedure.

Values from 1 to 4 invoke increasing effort to find larger numbers of solutions. Higher values are more expensive in terms of time and memory but are likely to yield more solutions.

Default: 0

value	meaning
0	Automatic Its default value, 0 , lets Cplex choose which intensity to apply.
1	Mild: generate few solutions quickly For value 1, the performance of MIP optimization is not affected. There is no slowdown and no additional consumption of memory due to this setting. However, populate will quickly generate only a small number of solutions. Generating more than a few solutions with this setting will be slow. When you are looking for a larger number of solutions, use a higher value of this parameter.
2	Moderate: generate a larger number of solutions For value 2, some information is stored in the branch and cut tree so that it is easier to generate a larger number of solutions. This storage has an impact on memory used but does not lead to a slowdown in the performance of MIP optimization. With this value, calling populate is likely to yield a number of solutions large enough for most purposes. This value is a good choice for most models.
3	Aggressive: generate many solutions and expect performance penalty For value 3, the algorithm is more aggressive in computing and storing information in order to generate a large number of solutions. Compared to values 1 and 2, this value will generate a larger number of solutions, but it will slow MIP optimization and increase memory consumption. Use this value only if setting this parameter to 2 does not generate enough solutions.
4	Very aggressive: enumerate all practical solutions For value 4, the algorithm generates all solutions to your model. Even for small models, the number of possible solutions is likely to be huge; thus enumerating all of them will take time and consume a large quantity of memory.

solnpoolmerge (*string*): solution pool file name for merged solutions ↩

Similar to **solnpool** this option enables you to generate and store multiple solutions to a MIP problem. The option expects a GDX filename. This GDX file contains all variables with an additional first index (determined through **SolnPoolPrefix**) as parameters (Cplex only reports the primal solution). Inside your GAMS program you can process the GDX file and read all solutions in one read operation. Please check the GAMS/Cplex solver guide document for further solution pool options and the example model **solnpool.gms** from the GAMS model library.

solnpoolnumsym (*integer*): maximum number of variable symbols when writing merged solutions ↩

Default: 10

solnpoolpop (*integer*): methods to populate the solution pool ↩

Regular MIP optimization automatically adds incumbents to the solution pool as they are discovered. Cplex also provides a procedure known as *populate* specifically to generate multiple solutions. You can invoke this procedure either as an alternative to the usual MIP optimizer or as a successor to the MIP optimizer. You can also invoke this procedure many times in a row in order to explore the solution space differently (see option **SolnPoolPopRepeat**). In particular, you may invoke this procedure multiple times to find additional solutions, especially if the first solutions found are not satisfactory.

Default: 1

value	meaning
1	Just collect the incumbents found during regular optimization
2	Calls the populate procedure

solnpoolpopdel (*string*): file with solution numbers to delete from the solution pool ↩

After the GAMS program specified in **SolnPoolPopRepeat** determined to continue the search for alternative solutions, the file specified by this option is read in. The solution numbers present in this file will be delete from the solution pool before the populate routine is called again. The file is automatically deleted by the GAMS/Cplex link after processing.

solnpoolpoprepeat (*string*): method to decide if populating the solution should be repeated ↩

After the termination of the populate procedure (see option **SolnPoolPop**). The GAMS program specified in this option will be called which can examine the solutions in the solution pool and can decide to run the populate procedure again. If the GAMS program terminates normally (not compilation or execution time error) the search for new alternative solutions will be repeated.

solnpoolprefix (*string*): file name prefix for GDX solution files ↩

Default: soln

solnpoolreplace (*integer*): strategy for replacing a solution in the solution pool ↩

Default: 0

value	meaning
0	Replace the first solution (oldest) by the most recent solution; first in, first out
1	Replace the solution which has the worst objective
2	Replace solutions in order to build a set of diverse solutions

solutiontype (*integer*): type of solution (basic or non basic) for an LP or QP ↩

Specifies the type of solution (basic or non basic) that CPLEX attempts to compute for a linear program (LP) or for a quadratic program (QP). In this context, basic means having to do with the basis, and non basic applies to the variables and constraints not participating in the basis.

By default (that is, when the value of this parameter is 0 (zero) automatic), CPLEX seeks a basic solution (that is, a solution with a basis) for all linear programs (LP) and for all quadratic programs (QP).

When the value of this parameter is 1 (one), CPLEX seeks a basic solution, that is, a solution that includes a basis with a basic status for variables and constraints. In other words, CPLEX behaves the same way for the values 0 (zero) and 1 (one) of this parameter.

When the value of this parameter is 2, CPLEX seeks a pair of primal-dual solution vectors. This setting does not prevent CPLEX from producing status information, but in seeking a pair of primal-dual solution vectors, CPLEX possibly may not produce basic status information; that is, it is possible that CPLEX does not produce status information about which variables and constraints participate in the basis at this setting.

Do not use the deprecated value -1 (minus one) of the parameter barrier **crossover** algorithm to turn off crossover of the barrier algorithm but use this parameter to indicate that a primal-dual pair is sufficient.

Default: 0

value	meaning
0	Automatic
1	Basic solution
2	primal-dual pair

solvefinal (*boolean*): switch to solve the problem with fixed discrete variables ↩

Sometimes the solution process after the branch-and-cut that solves the problem with fixed discrete variables takes a long time and the user is interested in the primal values of the solution only. In these cases, **solvefinal** can be used to turn this final solve off. Without the final solve no proper marginal values are available and only NAs are returned to GAMS.

Default: 1

value	meaning
0	Do not solve the fixed problem
1	Solve the fixed problem and return duals

startalg (*integer*): MIP starting algorithm ↩

Selects the algorithm to use for the initial relaxation of a MIP.

Default: 0

value	meaning
0	Automatic
1	Primal simplex

value	meaning
2	Dual simplex
3	Network simplex
4	Barrier
5	Sifting
6	Concurrent

strongcandlim (*integer*): size of the candidates list for strong branching ↔

Limit on the length of the candidate list for strong branching ([VarSel](#) = 3).

Default: 10

strongitlim (*integer*): limit on iterations per branch for strong branching ↔

Limit on the number of iterations per branch in strong branching ([VarSel](#) = 3). The default value of 0 causes the limit to be chosen automatically which is normally satisfactory. Try reducing this value if the time per node seems excessive. Try increasing this value if the time per node is reasonable but Cplex is making little progress.

Default: 0

subalg (*integer*): algorithm for subproblems ↔

Strategy for solving linear sub-problems at each node.

Default: 0

value	meaning
0	Automatic
1	Primal simplex
2	Dual simplex
3	Network optimizer followed by dual simplex
4	Barrier with crossover
5	Sifting

submipodelim (*integer*): limit on number of nodes in an RINS subMIP ↔

Controls the number of nodes explored in an RINS subMIP. See option [RINSHeur](#).

Default: 500

submipscale (*integer*): scale the problem matrix when CPLEX solves a subMIP during MIP optimization ↔

Default: 0

value	meaning
-1	No scaling
0	Standard scaling
1	Modified, more aggressive scaling method

submipstartalg (*integer*): starting algorithm for a subMIP of a MIP ↩

Default: 0

value	meaning
0	Automatic
1	Primal simplex
2	Dual simplex
3	Network simplex
4	Barrier
5	Sifting
6	Concurrent

submipsubalg (*integer*): algorithm for subproblems of a subMIP of a MIP ↩

Default: 0

value	meaning
0	Automatic
1	Primal simplex
2	Dual simplex
3	Network optimizer followed by dual simplex
4	Barrier with crossover
5	Sifting

symmetry (*integer*): symmetry breaking cuts ↩

Determines whether symmetry breaking cuts may be added, during the preprocessing phase, to a MIP model.

Default: -1

value	meaning
-1	Automatic
0	Turn off symmetry breaking
1	Moderate level of symmetry breaking
2	Aggressive level of symmetry breaking
3	Very aggressive level of symmetry breaking
4	Highly aggressive level of symmetry breaking
5	Extremely aggressive level of symmetry breaking

threads (*integer*): global default thread count ↩

Synonym: gthreads

Default number of parallel threads allowed for any solution method. Non-positive values are interpreted as the number of cores to leave free so setting threads to 0 uses all available cores while setting threads to -1 leaves one core free for other tasks. Cplex does not understand negative values for the **threads** parameter. GAMS/Cplex will translate this is a non-negative number by applying the following formula: $\max(1, \text{number of cores} - |\text{threads}|)$

Default: GAMS Threads

tilim (*real*): overrides the GAMS ResLim option ↩

Synonym: reslim

The time limit setting determines the amount of time in seconds that Cplex will continue to solve a problem. This Cplex option overrides the GAMS ResLim option. Any non-negative value is valid.

Default: GAMS ResLim

trelim (*real*): maximum space in memory for tree ↩

Sets an absolute upper limit on the size (in megabytes) of the branch and cut tree. If this limit is exceeded, Cplex terminates optimization.

Default: 1e+075

tuning (*string*): invokes parameter tuning tool ↩

Invokes the Cplex parameter tuning tool. The mandatory value following the keyword specifies a GAMS/Cplex option file. All options found in this option file will be used but not modified during the tuning. A sequence of file names specifying existing problem files may follow the option file name. The files can be in [LP](#), [MPS](#) or [SAV](#) format. Cplex will tune the parameters either for the problem provided by GAMS (no additional problem files specified) or for the suite of problems listed after the GAMS/Cplex option file name without considering the problem provided by GAMS. Due to technical reasons a single option input line is limited by 256 characters. If the list of model files exceeds this length you can provide a second, third, ... line starting again with keyword **tuning** and a list of model instance files.

The result of such a tuning run is the updated GAMS/Cplex option file with a tuned set of parameters. The solver and model status returned to GAMS will be **NORMAL COMPLETION** and **NO SOLUTION**. More details on Cplex tuning can be found on [IBM's web page](#). Tuning is incompatible with the BCH facility and other advanced features of GAMS/Cplex.

tuningdettlim (*real*): tuning deterministic time limit per model or suite ↩

Default: 1e+007

tuningdisplay (*integer*): level of information reported by the tuning tool ↩

Specifies the level of information reported by the tuning tool as it works.

Default: 1

value	meaning
0	Turn off display
1	Display standard minimal reporting
2	Display standard report plus parameter settings being tried
3	Display exhaustive report and log

tuningmeasure (*integer*): measure for evaluating progress for a suite of models ↩

Controls the measure for evaluating progress when a suite of models is being tuned. Choices are mean average and minmax of time to compare different parameter sets over a suite of models

Default: 1

value	meaning
1	mean average
2	minmax

tuningrepeat (*integer*): number of times tuning is to be repeated on perturbed versions ↩

Specifies the number of times tuning is to be repeated on perturbed versions of a given problem. The problem is perturbed automatically by Cplex permuting its rows and columns. This repetition is helpful when only one problem is being tuned, as repeated perturbation and re-tuning may lead to more robust tuning results. This parameter applies to only one problem in a tuning session.

Default: 1

tuningtilim (*real*): tuning time limit per model or suite ↩

Sets a time limit per model and per test set (that is, suite of models).

As an example, suppose that you want to spend an overall amount of time tuning the parameter settings for a given model, say, 2000 seconds. Also suppose that you want Cplex to make multiple attempts within that overall time limit to tune the parameter settings for your model. Suppose further that you want to set a time limit on each of those attempts, say, 200 seconds per attempt. In this case you need to specify an overall time limit of 2000 using GAMS option **reslim** or Cplex option **TiLim** and **tuningtilim** to 200.

Default: 0.2*GAMS ResLim

usercutcall (*string*): the GAMS command line to call the cut generator ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

usercutfirst (*integer*): calls the cut generator for the first n nodes ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 10

usercutfreq (*integer*): determines the frequency of the cut generator model calls ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 10

usercutinterval (*integer*): determines the interval when to apply the multiplier for the frequency of the cut generator model calls ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 100

usercutmult (*integer*): determines the multiplier for the frequency of the cut generator model calls ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 2

usercutnewint (*boolean*): calls the cut generator if the solver found a new integer feasible solution ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 1

usergdxin (*string*): the name of the GDX file read back into Cplex ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: bchin.gdx

usergdxname (*string*): the name of the GDX file exported from the solver with the solution at the node ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: bchout.gdx

usergdxnameinc (*string*): the name of the GDX file exported from the solver with the incumbent solution ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: bchout.i.gdx

usergdxprefix (*string*): prefixes usergdxin, usergdxname, and usergdxnameinc ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

usergdxsol (*string*): the name of the GDX file exported by Cplex to store the solution of extra columns ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: bchsol.gdx

userheurcall (*string*): the GAMS command line to call the heuristic ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

userheurfirst (*integer*): calls the heuristic for the first n nodes ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 10

userheurfreq (*integer*): determines the frequency of the heuristic model calls ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 10

userheurinterval (*integer*): determines the interval when to apply the multiplier for the frequency of the heuristic model calls ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 100

userheurmultip (*integer*): determines the multiplier for the frequency of the heuristic model calls ↩

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 2

userheurnewint (*boolean*): calls the heuristic if the solver found a new integer feasible solution ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 1

userheurobjfirst (*integer*): Similar to UserHeurFirst but only calls the heuristic if the relaxed objective promises an improvement ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 0

userincbcall (*string*): the GAMS command line to call the incumbent checking program ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

userincbicall (*string*): the GAMS command line to call the incumbent reporting program ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

userjobid (*string*): postfixes lf, o on call adds –userjobid to the call. Postfixes gdxname, gdxnameinc and gdxin ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

userkeep (*boolean*): calls gamskeep instead of gams ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 0

varsel (*integer*): variable selection strategy at each node ↔

This option is used to set the rule for selecting the branching variable at the node which has been selected for branching. The default value of 0 allows Cplex to select the best rule based on the problem and its progress.

Default: 0

value	meaning
-1	Branch on variable with minimum infeasibility This rule may lead more quickly to a first integer feasible solution, but will usually be slower overall to reach the optimal integer solution.
0	Branch variable automatically selected
1	Branch on variable with maximum infeasibility This rule forces larger changes earlier in the tree, which tends to produce faster overall times to reach the optimal integer solution.
2	Branch based on pseudo costs Generally, the pseudo-cost setting is more effective when the problem contains complex trade-offs and the dual values have an economic interpretation.
3	Strong Branching This setting causes variable selection based on partially solving a number of subproblems with tentative branches to see which branch is most promising. This is often effective on large, difficult problems.
4	Branch based on pseudo reduced costs

warninglimit (*integer*): determines how many times warnings of a specific type (datacheck=2) will be displayed ↩

By default, when modeling assistance is turned on via the [data consistency checking parameter](#), CPLEX will display 10 warnings for a given modeling issue and then omit the rest. This parameter controls this limit and allows the user to display all of the warnings if desired. CplexD will suppress some meaningless warnings. In order to see all warnings change the value to its negative.

Default: 10

workdir (*string*): directory for working files ↩

The name of an existing directory into which Cplex may store temporary working files. Used for MIP node files and by out-of-core Barrier.

Default: current or project directory

workeralgorithm (*integer*): set method for optimizing benders subproblems ↩

Default: 0

value	meaning
0	Automatic
1	Primal Simplex
2	Dual Simplex
3	Network Simplex
4	Barrier
5	Sifting

workmem (*real*): memory available for working storage ↩

Upper limit on the amount of memory, in megabytes, that Cplex is permitted to use for working files. See parameter [WorkDir](#).

Default: 128

writeannotation (*string*): produce a Cplex annotation file ↩

writebas (*string*): produce a Cplex basis file ↩

Write a basis file.

writeflt (*string*): produce a Cplex solution pool filter file ↩

Write the diversity filter to a Cplex FLT file.

writelp (*string*): produce a Cplex LP file ↩

Write a file in Cplex LP format.

writemps (*string*): produce a Cplex MPS file ↩

Write an MPS problem file.

writemst (*string*): produce a Cplex mst file ↩

Write a Cplex MST (containing the MIP start) file.

writeord (*string*): produce a Cplex ord file ↩

Write a Cplex ORD (containing priority and branch direction information) file.

writeparam (*string*): produce a Cplex parameter file with all active options ↩

Write a Cplex parameter (containing all modified Cplex options) file.

writepre (*string*): produce a Cplex LP/MPS/SAV file of the presolved problem ↩

Synonym: writepremps

Write a Cplex LP, MPS, or SAV file of the presolved problem. The file extension determines the problem format. For example, `WritePre presolved.lp` creates a file `presolved.lp` in Cplex LP format.

writeprob (*string*): produce a Cplex problem file and infers the type from the extension ↩

Write a problem file in a format inferred from the extension. Possible formats are

- **SAV**: Binary matrix and basis file
- **MPS**: MPS format
- **LP**: CPLEX LP format with names modified to conform to LP format
- **REW**: MPS format, with all names changed to generic names
- **RLP**: LP format, with all names changed to generic names
- **ALP**: LP format, with generic name of each variable, type of each variable, bound of each variable. If the file name ends with `.bz2` or `.gz`, a compressed file is written.

writesav (*string*): produce a Cplex binary problem file ↩

Write a binary problem file.

zerohalfcuts (*integer*): zero-half cuts ↩

Decides whether or not to generate zero-half cuts for the problem. The value 0, the default, specifies that the attempt to generate zero-half cuts should continue only if it seems to be helping. If the dual bound of your model does not make sufficient progress, consider setting this parameter to 2 to generate zero-half cuts more aggressively.

Default: 0

value	meaning
-1	Off
0	Automatic
1	Generate zero-half cuts moderately
2	Generate zero-half cuts aggressively

5.16 Deterministic Equivalent (DE)

Martha Loewe

5.16.1 Introduction

DE is a solver for stochastic programs modeled with GAMS Extended Mathematical Programming for Stochastic Programming (EMP SP). DE can solve multi-stage LP, MIP, QCP, NLP and MINLP stochastic programming models. For details about EMP SP and the syntax to modify an existing GAMS model to be an stochastic programming model in GAMS EMP SP see [Stochastic Programming](#). A list of DE solver options is given at the end of this document.

Stochastic programs are mathematical programs that include data that is not known with certainty, but is approximated by probability distributions. The simplest form of a stochastic program is the two-stage stochastic linear program with recourse. In mathematical terms it is defined as follows.

Let $x \in \mathbb{R}^n$ and $y \in \mathbb{R}^m$ be two variables and let the set of all realizations of the unknown data be given by Ω , $\Omega = \{\omega_1, \dots, \omega_S\} \subseteq \mathbb{R}^r$, where r is the number of the random variables representing the uncertain parameters. Then the stochastic program is given by

$$\begin{aligned} \text{Min}_x \quad & z = c^T x + \mathbb{E}[Q(x, \omega)] \\ \text{s.t.} \quad & Ax = b, \quad x \geq 0, \\ \text{where} \quad & Q(x, \omega) = \text{Min}_y \\ \text{s.t.} \quad & T_\omega x + W_\omega y(\omega) = h_\omega, \quad y(\omega) \geq 0, \quad \forall \omega \in \Omega. \end{aligned} \tag{5.1}$$

The first two lines define the first-stage problem and the last two lines define the second-stage problem. In the first stage, x is the decision variable, c^T represents the cost coefficients of the objective function and $\mathbb{E}[Q(x, \omega)]$ denotes the expected value of the optimal solution of the second stage problem. In addition, A denotes the coefficients and b the right-hand side of the first stage constraints. In the second stage, y is the decision variable, T represents the transition matrix, W the recourse matrix (cost of recourse) and h the right-hand side of the second stage constraints. Note that all parameters and the decision variable of the second stage are dependent on ω . The objective variable z is also a random variable, since it is a function of ω . As a random variable cannot be optimized, DE automatically optimizes the *expected value* of the objective variable z . DE is also able to optimize other risk measures, as will be discussed later.

In the first stage, a decision has to be made before the realization of the uncertain data is clear. The optimal solution of the first stage is fixed and only then the values that the uncertain parameters take will become known. Given the fixed solution of the first stage and the new data, in the second stage recourse action can be taken and the optimal solution determined. Each possible realization of the uncertain data is represented by an $\omega_s \in \Omega$ and is called a *scenario*. The objective is to find a feasible solution x that minimizes the total cost, namely the sum of the first-stage costs and the expected second-stage costs.

One of the most common methods to solve a two-stage stochastic LP is to build and solve the *deterministic equivalent*. Assume that the uncertain parameters follow a (finite) discrete distribution and that each scenario ω_s occurs with probability $P(\omega_s) = p_s$ for all $s = 1, \dots, S$ and $\sum_s p_s = 1$. So $\mathbb{E}[Q(x, \omega)] = \sum_s p_s q^T y_s$, where y_s denotes the optimal second-stage decision for the scenario ω_s . Then the deterministic equivalent can be expressed as follows:

$$\begin{array}{rclcl}
c^T x & + & p_1 q^T y_1 & + & p_2 q^T y_2 & + & \dots & + & p_S q^T y_S \\
\text{s.t.} & & & & & & & & \\
Ax & & & & & & & & = & b \\
T_1 x & + & W_1 y_1 & & & & & & = & h_1 \\
T_2 x & & & + & W_2 y_2 & & & & = & h_2 \\
\vdots & & & + & & & \ddots & & \vdots & \\
T_S x & & & & & & & + & W_S y_S & = & h_S \\
x \in \mathbb{R}^n & & y_1 \in \mathbb{R}^m & & y_2 \in \mathbb{R}^m & & & & y_S \in \mathbb{R}^m & &
\end{array} \tag{5.2}$$

Note that for stochastic linear programs the deterministic equivalent is just a very large linear program.

The solver DE automatically generates the deterministic equivalent of a stochastic program and then hands it over for solution to a solver, termed the *subsolver*. The subsolver is the default solver for the type of model to be solved. The user may choose another subsolver with the option [subsolver](#).

If modelers want to use DE, they may either add the option

```
option emp = de;
```

before the `solve` statement in the model or they may choose the solver DE on the command line, e.g.

```
gams mymodel.gms emp=de
```

5.16.2 Random Variables

Random variables and their distributions and stages determine the number of scenarios in the model and thus the number of equations that are generated for the deterministic equivalent. If there are two or more random variables in one stage they may be jointly distributed or not.

Assume that there is a two-stage stochastic model $\mathcal{M}_2$ that has two random variables a and b in the second stage. The random variables both follow a discrete distribution, the uncertain data for a is given by Ω_a and the uncertain data for b is given by Ω_b . If the random variables are *not* jointly distributed, then $|\Omega_a| \times |\Omega_b|$ scenarios are generated. If the random variables are jointly distributed, then we need to have $|\Omega_a| = |\Omega_b|$ and the number of scenarios is $|\Omega_a|$.

In addition to two-stage stochastic models, DE can also solve multi-stage stochastic models. Let $\mathcal{M}_4$ be a stochastic model with four stages. In each of the stages after the first stage new data is revealed that was unknown in the previous stages. Assume that in each stage there is just one random variable. Let Ω_I denote the uncertain data in the second stage and Ω_{II} and Ω_{III} represent the uncertain data of the third and fourth stage respectively. Let $|\Omega_I| = n_1$, $|\Omega_{II}| = n_2$ and $|\Omega_{III}| = n_3$. DE builds the deterministic equivalent of this model by recursively generating a scenario tree. In the second stage the number of scenarios is n_1 , in the third stage there are $n_1 \times n_2$ scenarios and in the fourth stage there are $n_1 \times n_2 \times n_3$ scenarios. Note that the number of scenarios in the model equals the number of scenarios in the last stage. However, the number of equations generated for the deterministic equivalent is the sum of the scenarios in each stage, so in this example it is $n_1 + n_1 \times n_2 + n_1 \times n_2 \times n_3 = n_1 \times (1 + n_2 \times (1 + n_3))$.

The following figure illustrates the scenario tree of a stochastic model with four stages.

5.16.4 The Expected Value Problem

Consider the special case where the sample size is 1 and the "sampled" value equals the expected value of the random variable. This entails that the random variable is replaced by its expected value. The resulting model is deterministic and is called the Expected Value Program. DE facilitates solving the Expected Value Problem through the option `solveEVProb`. If this option is specified in the option file (see example below) the Expected Value Problem is solved after the original stochastic model and the solution is reported. In addition, DE offers the option to choose a separate subsolver for the Expected Value Problem, the option `evsubsolver`.

In the following example the stochastic model is solved with the subsolver Conopt and the Expected Value Problem is solved with the subsolver Minos.

```
$onecho > de.opt
subsolver conopt
solveEVProb
evsubsolver minos
$offecho
mymodel.optfile=1;
solve mymodel min obj using emp scenario dict;
```

Note that the option `solveEVProb` is not defined for models with chance constraints and models featuring VaR and CVaR. These model types are discussed in the next section.

5.16.5 What types of models can DE handle?

As mentioned earlier, DE can solve two-stage and multi-stage stochastic linear, quadratic and nonlinear models and the mixed-integer versions of all these models. There are two further classes of stochastic models that DE is equipped to solve: stochastic programs with chance constraints and stochastic programs with other risk measures such as Variance at Risk (VaR) and Conditional Variance at Risk (CVaR). CVaR is also called Expected Shortfall.

In stochastic programs with chance constraints the goal is to make an optimal decision prior to the realization of random data while allowing the constraints to be violated with a certain probability. Mathematically, a stochastic linear program with chance constraints can be expressed as follows:

$$\begin{array}{ll} \text{Min}_x & c^T x \\ \text{s.t.} & P(Ax \leq b) \geq p \\ & x \geq 0, \end{array} \quad (5.3)$$

where $x \in \mathbb{R}^n$ is the decision variable and c^T denotes the coefficients of the objective function, $A \in \mathbb{R}^{m \times n}$ is a random matrix and represents the coefficients and $b \in \mathbb{R}^m$ is a random vector and denotes the right-hand side of the constraints. The distinctive feature of stochastic programs with chance constraints is that the constraints (or some of them) may be violated with probability $\epsilon = 1 - p$, where $0 < p \leq 1$.

DE offers three reformulation options to solve stochastic programs with chance constraints: a reformulation using a mixed-integer program with big M notation, a convex hull reformulation and the use of indicator variables and indicator constraints. Note that the default is the MIP reformulation (the default value of M is set to 10000 and can be customized). With the option `ccreform` the reformulation method can be determined by the user.

For details on single and joint chance constraints and examples how to use the option `ccreform`, see the section [Chance Constraints with EMP](#) in the EMP manual. Note that random variables in programs with

chance constraints may follow discrete or continuous probability distributions. Note further that there are no stages in stochastic programs with chance constraints.

As mentioned earlier, DE automatically optimizes the expected value of the objective function variable. DE also supports other risk measures, such as VaR and CVaR. In mathematical terms, DE is able to solve the following:

$$\text{Min}_x \quad \mathcal{R}(z), \quad (5.4)$$

where z represents the objective function variable and $\mathcal{R}$ denotes a risk measure such as the Expected Value, VaR and CVaR or a combination of risk measures (e.g. the weighted sum of Expected Value and CVaR). In addition, the modeler can also choose to trade off risk measures. For more details about risk measures see section [Risk Measures with EMP](#) in the EMP manual.

5.16.6 Reformulation Techniques

In this section some details are given about the reformulations that DE is performing behind the scenes.

5.16.6.1 Simple two-stage stochastic model

As mentioned previously, DE converts a stochastic model into its deterministic equivalent. Using the model `nbsimple.gms` from the GAMS EMP model library as an example, we show how exactly the deterministic equivalent is built. Note that this model is also discussed in detail in the section [A Simple Example: The News Vendor Problem](#) of the EMP manual.

The model is given by the following equations:

$$\text{Max}_x \quad z(x) = -cx + \mathbb{E}[Q(x, \omega)], \quad x \geq 0, \quad (5.5)$$

where

$$\begin{aligned} Q(x, \omega) = & \text{Max}_{s, i, l} \quad vs(\omega) - hi(\omega) - pl(\omega) \\ \text{s.t.} \quad & x - s(\omega) - i(\omega) = 0 \\ & s(\omega) + l(\omega) = d(\omega) \\ & s(\omega), i(\omega), l(\omega) \geq 0 \quad \forall \omega \in \Omega. \end{aligned}$$

Here c , v , h and p are some given parameters, the first-stage decision variable is x , the second-stage decision variables are s , i and l and the uncertain data is represented by the random variable $d(\omega)$. We assume that the annotations specify that d follows a Normal distribution and the sample size to approximate this continuous distribution is 4 (where all scenarios are equally likely, so $p(s) = 0.25$).

First, DE draws 4 values from the Normal distribution specified in the annotations. These 4 values are the basis for the 4 scenarios that are generated. For each scenario, a separate equation for the two second-stage constraints is built (that are 8 equations). In the process, for each of the three decision variables of the second stage 4 variables are generated since the second-stage decision variables may take different values for each scenario. Next, an equation for the profit for each scenario is generated (4 equations) and finally, the equation to compute the average profit is built. So there are a total of 13 equations. They are given here:

$$\begin{aligned}
x - s_1 - i_1 &= 0 \\
x - s_2 - i_2 &= 0 \\
x - s_3 - i_3 &= 0 \\
x - s_4 - i_4 &= 0 \\
s_1 + l_1 &= d_1 \\
s_2 + l_2 &= d_2 \\
s_3 + l_3 &= d_3 \\
s_4 + l_4 &= d_4 \\
z_1 &= -cx + vs_1 - hi_1 - pl_1 \\
z_2 &= -cx + vs_2 - hi_2 - pl_2 \\
z_3 &= -cx + vs_3 - hi_3 - pl_3 \\
z_4 &= -cx + vs_4 - hi_4 - pl_4 \\
z &= 0.25z_1 + 0.25z_2 + 0.25z_3 + 0.25z_4
\end{aligned} \tag{5.6}$$

Note that there is only one realization of the first-stage decision variable x while for the second-stage decision variables there as many realizations as there are scenarios.

5.16.6.2 A multi-stage stochastic model

DE recursively builds a scenario tree to generate the deterministic equivalent of multi-stage models. We take the model `inventory` from the [EMP manual](#) to demonstrate how this is done. The 4-stage model is given by the following equations:

$$\begin{aligned}
\text{Max}_{y_1, i_1} \quad & z = -\alpha y_1 - \gamma i_1 + \mathbb{E}[Q((y_1, i_1), \omega_I) + \mathbb{E}[Q((y_1, i_1), \omega_{II}) + \mathbb{E}[Q((y_1, i_1), \omega_{III})]]] \\
\text{s.t.} \quad & i_1 = y_1 \\
& y_1, i_1 \geq 0,
\end{aligned}$$

where

$$\begin{aligned}
Q((y_1, i_1), \omega_\zeta) &= \text{Max}_{s_t, y_t, i_t} \beta s_t(\omega_\zeta) - \alpha y_t(\omega_\zeta) - \delta i_t(\omega_\zeta) \\
\text{s.t.} \quad & i_{t-1} + y_t = s_t + i_t \\
& s_t \leq i_{t-1} \\
& s_t \leq d_t(\omega_\zeta) \\
& i_t \leq \kappa \\
& s_t, y_t, i_t \geq 0 \quad \text{for } t = 2, 3, 4.
\end{aligned}$$

Here y_1 and i_1 are the first-stage decision variables and y_t , i_t and s_t are the decision variables of the later stages; α , β , γ , δ and κ denote fixed parameters. The uncertain data is represented by the random variable $d_t(\omega_\zeta)$, where $\omega_\zeta \in \Omega_\zeta$ and $\zeta = \text{I, II, III}$. Note that s_t , y_t and i_t depend on the realization of d_t . Now assume that d_t follows a continuous distribution and the sample size to approximate this distribution is just 3 for stages 2 to 4. Note that in multi-stage models the sample size may vary for each stage. Note further that for all practical purposes this sample size is too small, it was chosen here for reasons of clarity of exposition. As usual, the distribution(s) and sample size(s) are specified in the annotations. Observe that the last constraint ($i_t \leq \kappa$) is implemented as a bound on the variable i_t , not as an equation. So, in addition to the objective equations, there is one equation in the first stage and three equations in each of the later stages.

This model is reformulated in the following way. First, an equation for the first stage constraint is generated. Secondly, three realizations of d_2 are chosen through a sampling procedure, so there are three scenarios at stage 2. For each of these three realizations of the random variable the equations for the second stage are generated (9 equations). Thirdly, three realizations of d_3 are sampled for stage 3. Each of these three realizations may follow one of the three scenarios of the second stage, so there are nine scenarios in stage 3 and hence $9 \times 3 = 27$ equations are generated for stage 3. The procedure is repeated in stage 4 where there are 27 scenarios and $27 \times 3 = 81$ equations. Next, the value of the objective variable for each scenario is computed by generating 27 equations for z_s and finally, an equation to compute z is built, where $z = \sum_s p(s)z_s$.

5.16.6.3 Chance Constraints

Models with chance constraints are reformulated as mixed integer problems by default. This reformulation is discussed in detail in the section [Chance Constraints with EMP](#) in the EMP manual. Reformulations using a convex hull or indicator variables and indicator constraints are also possible. The reformulation method may be determined by the user with the option [ccreform](#).

5.16.6.4 Computing VaR

Models involving VaR are reformulated using mixed integer programs with big M notation. By the example model `portfolio.gms` we demonstrate how this is done. This model is discussed in the section [Value at Risk \(VaR\)](#) in the EMP manual. The model is given by the following equations:

$$\begin{aligned} \text{Max} \quad & \underline{VaR}_\theta[R] \\ \text{s.t} \quad & R = \sum_j w_j v_j(\omega) \quad \forall \omega \in \Omega \\ & \sum_j w_j = 1 \\ & w_j \geq 0, \end{aligned} \tag{5.7}$$

where $\underline{VaR}_\theta$ is the VaR at the lower θ th percentile, the variable R is the return (and is a function of the random variable $v_j(\omega)$), w_j the weight associated with each asset j and $v_j(\omega)$ is the (random variable) return of each asset j . The weights can also be interpreted as proportions of the amount to be invested, their sum must be 1. Note that w_j is the decision variable in this problem.

Let $y(s)$ be a binary variable that acts as an indicator variable. For each scenario, it equals 1 if the return $R \geq \underline{VaR}_\theta[R]$ and it is 0 otherwise. Then the model is reformulated to the following MIP:

$$\begin{aligned} \text{Max} \quad & \underline{VaR}_\theta[R] \\ \text{s.t} \quad & r(s) = \sum_j w_j v_j(s) \quad \forall s = 1, \dots, S \\ & r(s) \geq \underline{VaR}_\theta[R] - M(1 - y(s)) \quad \forall s = 1, \dots, S \\ & cc = 1 - \sum_s p(s)y(s) \\ & \sum_j w_j = 1 \\ & 0 \leq cc \leq \theta \\ & w_j \geq 0. \end{aligned} \tag{5.8}$$

Here $r(s)$ denotes the return per scenario and cc is a variable that represents the probability of violations (a violation occurs if in a scenario the return is smaller than $\underline{VaR}_\theta[R]$). As usual, $p(s)$ is the probability that a scenario occurs and M is the big M . The first three constraints together with the bounds on cc ensure that the probability of violations is smaller than or equal to θ .

Note that the default value for big M for models with VaR is 1000 (and it is different from the default value for big M for chance constraints). It may be customized with the option [varbigm](#).

5.16.6.5 Computing CVaR

Models with CVaR are reformulated by converting the annotations into new variables and equations. Using the model `portfolio.gms` as an example we demonstrate how this is done. This model features in the GAMS EMP library and is also discussed in the section [Conditional Value at Risk \(CVaR\)](#) in the EMP manual. The model is given by:

$$\begin{aligned} \text{Max} \quad & \underline{CVaR}_\theta[R] \\ \text{s.t} \quad & R = \sum_j w_j v_j(\omega) \quad \forall \omega \in \Omega \\ & \sum_j w_j = 1 \\ & w_j \geq 0, \end{aligned} \tag{5.9}$$

where $\underline{CVaR}_\theta$ is the CVaR at the left tail of the distribution at the confidence level θ and all other variables are as defined above. Note that again, w_j is the decision variable in this problem.

DE reformulates this model by introducing three new variables and three associated equations. Let $r(s)$ denote the return per scenario, t the target return to be achieved with probability approximately $1 - \theta$ and $d(s)$, $d(s) \geq 0$, the lower deviation from t per scenario. The equations follow.

$$\begin{aligned} r(s) &= \sum_j w_j v_j(s) \\ d(s) &\geq t - r(s) \\ \underline{CVaR}_\theta[R] &= t - \frac{1}{\theta} \sum p(s) d(s) \end{aligned} \tag{5.10}$$

Thus the model is reformulated to an LP and may be solved by an appropriate solver. It is easy to see that t equals $\underline{VaR}_\theta[R]$.

5.16.7 Logfile

The logfile gives much information about the solver progress. The following is the DE log output from running the **nbdiscjoint** model from the GAMS EMP Model Library:

```

First, the model in scalar form is generated. It has 5 equations, so the model statistics report 5 rows. Further, it has 6 positive variables, one free variable and 2 random variables, so there are 9 columns. A matrix form representation of the model with the variables as columns and the equations as rows has 19 non-zero entries. Next, DE generates the deterministic equivalent. The statistics for the deterministic equivalent indicate that there are 26 rows, 50 columns and 116 non-zero entries. The stochastic model has 6 scenarios, so for each second-stage equation there are 6 equations in the deterministic equivalent (i.e. a total of 24 equations). In addition, there is one first-stage equation and one equation to compute the expected value of the objective variable, which brings the sum total to 26 equations or rows. Similarly, for each second-stage variable in the stochastic model there are 6 variables in the deterministic equivalent (i.e. a total of 48 variables). In addition, there is the first-stage decision variable and a variable for the expected value of the objective adding up to a total of 50 variables or columns.

Note that the model type is identified as an LP and thus the default LP solver is invoked. In this case the subsolver is Cplex and most of the remainder of the logfile is output from the subsolver. At the end the mapping specified in the dictionary is performed.

The logfile of solving stochastic models with VaR or CVaR is similar. It reports that the model type is being determined, the deterministic equivalent built and then handed over to the appropriate subsolver to be solved. However, when solving stochastic programs with chance constraints there is much more happening behind the scenes. DE automatically hands over the model to the subsolver JAMS. By default, JAMS reformulates the model and generates a scalar version of it. The scalar version of the reformulated model is then handed back to the GAMS system to be solved by an appropriate subsolver. The logfile reports the progress of the subsolver until the model is solved. Then the solution from the GAMS subsolver is handed to JAMS and a list of disjunctions and their activity level is reported. (The equations in the scalar version of the reformulated model that may be left unsatisfied are called *disjunctions*. *Active* disjunctions refer to equations that are satisfied and *not active* disjunctions refer to equations that are not satisfied.)

Parts of the DE logfile from running the **simplechance** model from the GAMS EMP Model Library are given below. These parts of the logfile demonstrate the solution process for stochastic models with chance constraints that was just described.

5.16.8 Summary of DE Options

5.16.8.1 General Options

Option	Description	Default
correlationtype	Sample correlation type	0
subsolver	Subsolver to run	
subsolveropt	Optfile value to pass to the subsolver	1
svr_ls_antithetic	Sample variance reduction map to Lindo Antithetic algorithm	
svr_ls_latinsquare	Sample variance reduction map to Lindo Latin Square algorithm	
svr_ls_montecarlo	Sample variance reduction map to Lindo Montecarlo algorithm	

5.16.8.2 Options for chance constraint models

Option	Description	Default
ccreform	Reformulation option passed to JAMS	bigM
jamsopt	JAMS option file	

5.16.8.3 Options for recourse models

Option	Description	Default
evsubsolver	Subsolver to run on expected value problem	
evsubsolveropt	Optfile value to pass to the subsolver for expected value problem	1
maxnodes	Tree size limit	100000
solveEVProb	Solve and report the expected value solution	0
varbigm	Big M for Value at Risk reformulation	1000.0

5.16.9 Detailed Descriptions of DE Options

ccreform (*string*): Reformulation option passed to JAMS [↔](#)

This option determines how to formulate the indicator constraints of the chance constraints in the deterministic equivalent. The model is passed to JAMS for the actual reformulation and solution with a subsolver. The possible reformulation options are **bigM** [**big eps threshold**], **chull** [**big eps**], and **indic**. The **indic** setting only works with solver that understand the indicator syntax in a GAMS option file.

Default: **bigM**

correlationtype (*integer*): Sample correlation type [↔](#)

Default: 0

value	meaning
0	Pearson
1	Kendall
2	Spearman

evsubsolver (*string*): Subsolver to run on expected value problem [↔](#)

evsubsolveropt (*integer*): Optfile value to pass to the subsolver for expected value problem [↔](#)

Range: [1, 999]

Default: 1

jamsopt (*string*): JAMS option file [↔](#)

maxnodes (*integer*): Tree size limit [↔](#)

Range: [1000, ∞]

Default: 100000

solveEVProb (*no value*): Solve and report the expected value solution ↩

Default: 0

subsolver (*string*): Subsolver to run ↩

subsolveropt (*integer*): Optfile value to pass to the subsolver ↩

Range: [1, 999]

Default: 1

svr_ls_antithetic (*string*): Sample variance reduction map to Lindo Antithetic algorithm ↩

svr_ls_latinsquare (*string*): Sample variance reduction map to Lindo Latin Square algorithm ↩

svr_ls_montecarlo (*string*): Sample variance reduction map to Lindo Montecarlo algorithm ↩

varbigm (*real*): Big M for Value at Risk reformulation ↩

Default: 1000.0

5.17 DECIS

5.17.1 DECIS

5.17.1.1 Introduction

DECIS is a system for solving large-scale stochastic programs, i.e. programs that include parameters (coefficients and right-hand sides) that are not known with certainty, but are assumed to be known by their probability distribution. It employs Benders decomposition and advanced Monte Carlo sampling techniques. DECIS includes a variety of solution strategies, such as solving the universe problem, the expected value problem, Monte Carlo sampling within the Benders decomposition algorithm, and Monte Carlo pre-sampling. When using Monte Carlo sampling the user has the option of employing crude Monte Carlo without variance reduction techniques, or using as variance reduction techniques importance sampling or control variates, based on either an additive or a multiplicative approximation function. Pre-sampling is limited to using crude Monte Carlo only.

For solving linear and nonlinear programs (master and subproblems arising from the decomposition) DECIS interfaces with MINOS or CPLEX. MINOS, see Murtagh and Saunders (1983) [187], is a state-of-the-art solver for large-scale linear and nonlinear programs, and CPLEX is one of the fastest linear programming solvers available.

For details about the DECIS system consult the [DECIS User's Guide](#) see Infanger (1997) [131]. It includes a comprehensive mathematical description of the methods used by DECIS. In this Guide we concentrate on how to use DECIS directly from GAMS, and especially on how to model stochastic programs using the GAMS/DECIS interface. First, however, in section [What DECIS Can Do](#) we give a brief description of what DECIS can do and what solution strategies it uses. This description has been adapted from the DECIS User's Guide. In section [GAMS/DECIS](#) we discuss in detail how to set up a stochastic problem using GAMS/DECIS and give a description of the parameter setting and outputs obtained. In [Appendix A - GAMS/DECIS Illustrative Examples](#) we show the GAMS/DECIS formulation of two illustrative examples (APL1P and APL1PC) discussed in the DECIS User's Guide. A list of DECIS error messages are represented in [Appendix B - Error Messages](#).

In addition to using the syntax explained in this document, it is also possible to use the Extended Mathematical Programming (EMP) framework to define a stochastic program for GAMS/DECIS. This possibility was introduced with GAMS 23.8 and allows one to solve a stochastic program not only with GAMS/DECIS but also with GAMS/DE and GAMS/Lindo. Further information about this can be found in the chapter [Stochastic Programming \(SP\) with EMP](#).

5.17.1.2 What DECIS Can Do

DECIS solves two-stage stochastic linear programs with recourse:

$$\begin{aligned} \min \quad & z = cx + Ef^\omega y^\omega \\ \text{s.t.} \quad & Ax = b \\ & -B^\omega x + D^\omega y^\omega = d^\omega \\ & x, y^\omega \geq 0, \quad \omega \in \Omega. \end{aligned}$$

where x denotes the first-stage, y^ω the second-stage decision variables, c represents the first-stage and f^ω the second-stage objective coefficients, A , b represent the coefficients and right hand sides of the first-stage constraints, and B^ω , D^ω , d^ω represent the parameters of the second-stage constraints, where the transition matrix B^ω couples the two stages. In the literature D^ω is often referred to as the technology matrix or recourse matrix. The first stage parameters are known with certainty. The second stage parameters are

random parameters that assume outcomes labeled ω with probability $p(\omega)$, where Ω denotes the set of all possible outcome labels.

At the time the first-stage decision x has to be made, the second-stage parameters are only known by their probability distribution of possible outcomes. Later, after x has already been determined, an actual outcome of the second-stage parameters will become known, and the second-stage decision y^ω is made based on knowledge of the actual outcome ω . The objective is to find a feasible decision x that minimizes the total expected costs, the sum of first-stage costs and expected second-stage costs.

For discrete distributions of the random parameters, the stochastic linear program can be represented by the corresponding *equivalent deterministic linear program*:

$$\begin{array}{rcll}
 \min z & = & cx + p^1 f y^1 + p^2 f y^2 + \cdots + p^W f y^W & \\
 s/t & & Ax & = b \\
 & & -B^1 x + Dy^1 & = d^1 \\
 & & -B^2 x & + Dy^2 = d^2 \\
 & & \vdots & \\
 & & -B^W x & + Dy^W = d^W \\
 & & x, y^1, y^2, \dots, y^W & \geq 0,
 \end{array}$$

which contains all possible outcomes $\omega \in \Omega$. Note that for practical problems W is very large, e.g., a typical number could be 10^{20} , and the resulting equivalent deterministic linear problem is too large to be solved directly.

In order to see the two-stage nature of the underlying decision making process the following representation is also often used:

$$\begin{array}{rcl}
 \min & cx + E z^\omega(x) & \\
 & Ax & = b \\
 & x & \geq 0
 \end{array}$$

where

$$\begin{array}{rcl}
 z^\omega(x) & = & \min f^\omega y^\omega \\
 & D^\omega y^\omega & = d^\omega + B^\omega x \\
 & y^\omega & \geq 0, \omega \in \Omega = \{1, 2, \dots, W\}.
 \end{array}$$

DECIS employs different strategies to solve two-stage stochastic linear programs. It computes an exact optimal solution to the problem or approximates the true optimal solution very closely and gives a confidence interval within which the true optimal objective lies with, say, 95% confidence.

5.17.1.3 Representing Uncertainty

It is favorable to represent the uncertain second-stage parameters in a structure. Using $V = (V_1, \dots, V_h)$ an h -dimensional independent random vector parameter that assumes outcomes $v^\omega = (v_1, \dots, v_h)^\omega$ with probability $p^\omega = p(v^\omega)$, we represent the uncertain second-stage parameters of the problem as functions of the independent random parameter V :

$$f^\omega = f(v^\omega), \quad B^\omega = B(v^\omega), \quad D^\omega = D(v^\omega), \quad d^\omega = d(v^\omega).$$

Each component V_i has outcomes $v_i^{\omega_i}$, $\omega_i \in \Omega_i$, where ω_i labels a possible outcome of component i , and Ω_i represents the set of all possible outcomes of component i . An outcome of the random vector

$$v^\omega = (v_1^{\omega_1}, \dots, v_h^{\omega_h})$$

consists of h independent component outcomes. The set

$$\Omega = \Omega_1 \times \Omega_2 \times \dots \times \Omega_h$$

represents the crossing of sets Ω_i . Assuming each set Ω_i contains W_i possible outcomes, $|\Omega_i| = W_i$, the set Ω contains $W = \prod W_i$ elements, where $|\Omega| = W$ represents the number of all possible outcomes of the random vector V . Based on independence, the joint probability is the product

$$p^\omega = p_1^{\omega_1} p_2^{\omega_2} \dots p_h^{\omega_h}.$$

Let η denote the vector of all second-stage random parameters, e.g., $\eta = \text{vec}(f, B, D, d)$. The outcomes of η may be represented by the following general linear dependency model:

$$\eta^\omega = \text{vec}(f^\omega, B^\omega, d^\omega, d^\omega) = H v^\omega, \omega \in \Omega$$

where H is a matrix of suitable dimensions. DECIS can solve problems with such general linear dependency models.

5.17.1.4 Solving the Universe Problem

We refer to the universe problem if we consider all possible outcomes $\omega \in \Omega$ and solve the corresponding problem exactly. This is not always possible, because there may be too many possible realizations $\omega \in \Omega$. For solving the problem DECIS employs Benders decomposition, splitting the problem into a master problem, corresponding to the first-stage decision, and into subproblems, one for each $\omega \in \Omega$, corresponding to the second-stage decision. The details of the algorithm and techniques used for solving the universe problem are discussed in The DECIS User's Manual.

Solving the universe problem is referred to as strategy 4. Use this strategy only if the number of universe scenarios is reasonably small. There is a maximum number of universe scenarios DECIS can handle, which depends on your particular resources.

5.17.1.5 Solving the Expected Value Problem

The expected value problem results from replacing the stochastic parameters by their expectation. It is a linear program that can also easily be solved by employing a solver directly. Solving the expected value problem may be useful by itself (for example as a benchmark to compare the solution obtained from solving the stochastic problem), and it also may yield a good starting solution for solving the stochastic problem. DECIS solves the expected value problem using Benders decomposition. The details of generating the expected value problem and the algorithm used for solving it are discussed in the DECIS User's Manual. To solve the expected value problem choose strategy 1.

5.17.1.6 Using Monte Carlo Sampling

As noted above, for many practical problems it is impossible to obtain the universe solution, because the number of possible realizations $|\Omega|$ is way too large. The power of DECIS lies in its ability to compute excellent approximate solutions by employing Monte Carlo sampling techniques. Instead of computing the expected cost and the coefficients and the right-hand sides of the Benders cuts exactly (as it is done when solving the universe problem), DECIS, when using Monte Carlo sampling, estimates the quantities in each iteration using an independent sample drawn from the distribution of the random parameters. In addition to using crude Monte Carlo, DECIS uses importance sampling or control variates as variance reduction techniques.

The details of the algorithm and the different techniques used are described in the DECIS User's Manual. You can choose crude Monte Carlo, referred to as strategy 6, Monte Carlo importance sampling, referred to as strategy 2, or control variates, referred to as strategy 10. Both Monte Carlo importance sampling and control variates have been shown for many problems to give a better approximation compared to employing crude Monte Carlo sampling.

When using Monte Carlo sampling DECIS computes a close approximation to the true solution of the problem, and estimates a close approximation of the true optimal objective value. It also computes a confidence interval within which the true optimal objective of the problem lies, say with 95% confidence. The confidence interval is based on rigorous statistical theory. An outline of how the confidence interval is computed is given in the DECIS User's Manual. The size of the confidence interval depends on the variance of the second-stage cost of the stochastic problem and on the sample size used for the estimation. You can expect the confidence interval to be very small, especially when you employ importance sampling or control variates as a variance reduction technique.

When employing Monte Carlo sampling techniques you have to choose a sample size (set in the parameter file). Clearly, the larger the sample size the better will be the approximate solution DECIS computes, and the smaller will be the confidence interval for the true optimal objective value. The default value for the sample size is 100. Setting the sample size too small may lead to bias in the estimation of the confidence interval, therefore the sample size should be at least 30.

5.17.1.7 Monte Carlo Pre-sampling

We refer to pre-sampling when we first take a random sample from the distribution of the random parameters and then generate the approximate stochastic problem defined by the sample. The obtained approximate problem is then solved exactly using decomposition. This is in contrast to the way we used Monte Carlo sampling in the previous section, where we used Monte Carlo sampling in each iteration of the decomposition.

The details of the techniques used for pre-sampling are discussed in the DECIS User's Manual. DECIS computes the exact solution of the sampled problem using decomposition. This solution is an approximate solution of the original stochastic problem. Besides this approximate solution, DECIS computes an estimate of the expected cost corresponding to this approximate solution and a confidence interval within which the true optimal objective of the original stochastic problem lies with, say, 95% confidence. The confidence interval is based on statistical theory, while its size depends on the variance of the second-stage cost of the stochastic problem and on the sample size used for generating the approximate problem. In conjunction with pre-sampling no variance reduction techniques are currently implemented.

Using Monte Carlo pre-sampling you have to choose a sample size. Clearly, the larger the sample size you choose, the better will be the solution DECIS computes, and the smaller will be the confidence interval for the true optimal objective value. The default value for the sample size is 100. Again, setting the sample size too small may lead to a bias in the estimation of the confidence interval, therefore the sample size should be at least 30.

To use Monte Carlo pre-sampling choose strategy 8.

5.17.1.8 Regularized Decomposition

When solving practical problems, the number of Benders iterations can be quite large. In order to control the decomposition, with the hope to reduce the iteration count and the solution time, DECIS makes use of regularization. When employing regularization, an additional quadratic term is added to the objective of the master problem, representing the square of the distance between the best solution found so far (the incumbent solution) and the variable x . Using this term, DECIS controls the distance between solutions in successive decomposition iterations.

To enable regularization you have to set the corresponding parameter. You also have to choose the value of the constant ρ in the regularization term. The default is regularization disabled. Details of how DECIS carries out regularization are represented in the DECIS User's Manual.

Regularization is only implemented when using MINOS as the optimizer for solving subproblems. Regularization has proven to be helpful for problems that need a large number of Benders iteration when solved without regularization. Problems that need only a small number of Benders iterations without regularization are not expected to improve much with regularization, and may need even more iterations with regularization than without.

5.17.2 GAMS/DECIS

GAMS stands for General Algebraic Modeling Language, and is one of the most widely used modeling languages. Using DECIS directly from GAMS spares you from worrying about all the details of the input formats. It makes the problem formulation much easier but still gives you almost all the flexibility of using DECIS directly.

The link from GAMS to DECIS has been designed in such a way that almost no extensions to the GAMS modeling language were necessary for carrying out the formulation and solution of stochastic programs. In a future release of GAMS, however, additions to the language are planned that will allow you to model stochastic programs in an even more elegant way.

5.17.2.1 Setting up a Stochastic Program Using GAMS/DECIS

The interface from GAMS to DECIS supports the formulation and solution of stochastic *linear* programs. DECIS solves them using two-stage decomposition. The GAMS/DECIS interface resembles closely the structure of the SMPS (stochastic mathematical programming interface) discussed in the DECIS User's Manual. The specification of a stochastic problem using GAMS/DECIS uses the following components:

- the deterministic (core) model,
 - the specification of the decision stages,
 - the specification of the random parameters, and
 - setting DECIS as the optimizer to be used.
-

5.17.2.2 Starting with the Deterministic Model

The core model is a deterministic linear program where all random parameters are replaced by their mean or by a particular realization. One could also see it as a GAMS model without any randomness. It could be a deterministic model that you have, that you intend to expand to a stochastic one. Using DECIS with GAMS allows you to easily extend a deterministic linear programming model to a stochastic one. For example, the following GAMS model represents a deterministic version of the electric power expansion planning illustrative example discussed in Infanger (1994).

```
*   APL1P test model
*   Dr. Gerd Infanger, November 1997
*   Deterministic Program

set g generators / g1, g2/;
set dl demand levels /h, m, l/;

parameter alpha(g) availability / g1  0.68,  g2  0.64 /;
parameter cmin(g) min capacity / g1  1000,  g2  1000 /;
parameter cmax(g) max capacity / g1 10000,  g2 10000 /;
parameter c(g) investment      / g1  4.0,   g2  2.5 /;

table f(g,dl) operating cost
      h      m      l
g1    4.3    2.0    0.5
g2    8.7    4.0    1.0;

parameter d(dl) demand          / h  1040, m  1040, l  1040 /;
parameter us(dl) cost of unserved demand / h   10, m   10, l   10 /;

free variable tcost              total cost;
positive variable x(g)           capacity of generators;
positive variable y(g, dl)       operating level;
positive variable s(dl)          unserved demand;

equations
cost          total cost
cmin(g)       minimum capacity
cmax(g)       maximum capacity
omax(g)       maximum operating level
demand(dl)    satisfy demand;

cost .. tcost =e=      sum(g, c(g)*x(g))
                    + sum(g, sum(dl, f(g,dl)*y(g,dl)))
                    + sum(dl,us(dl)*s(dl));

cmin(g) ..  x(g) =g= cmin(g);
cmax(g) ..  x(g) =l= cmax(g);
omax(g) ..  sum(dl, y(g,dl)) =l= alpha(g)*x(g);
demand(dl) .. sum(g, y(g,dl)) + s(dl) =g= d(dl);

model apl1p /all/;

option lp=minos5;
solve apl1p using lp minimizing tcost;

scalar ccost capital cost;
scalar ocost operating cost;
```

```
ccost = sum(g, c(g) * x.l(g));
ocost = tcost.l - ccost;
display x.l, tcost.l, ccost, ocost, y.l, s.l;
```

5.17.2.3 Setting the Decision Stages

Next in order to extend a deterministic model to a stochastic one you must specify the decision stages. DECIS solves stochastic programs by two-stage decomposition. Accordingly, you must specify which variables belong to the first stage and which to the second stage, as well as which constraints are first-stage constraints and which are second-stage constraints. First stage constraints involve only first-stage variables, while second-stage constraints involve both first- and second-stage variables. You must specify the stage of a variable or a constraint by setting the stage suffix ".STAGE" to either one or two depending on if it is a first or second stage variable or constraint. For example, expanding the illustrative model above by

```
* setting decision stages
x.stage(g)      = 1;
y.stage(g, dl)  = 2;
s.stage(dl)     = 2;
cmin.stage(g)   = 1;
cmax.stage(g)   = 1;
omax.stage(g)   = 2;
demand.stage(dl) = 2;
```

would make $x(g)$ first-stage variables, $y(g, dl)$ and $s(dl)$ second-stage variables, $cmin(g)$ and $cmax(g)$ first-stage constraints, and $omax(g)$ and $demand(g)$ second-stage constraints. The objective is treated separately, you don't need to set the stage suffix for the objective variable and objective equation.

Note that the use of the `.stage` variable and equation suffix causes the GAMS scaling facility (i.e. the `.scale` suffix) to be unavailable. Stochastic models have to be scaled manually.

5.17.2.4 Specifying the Stochastic Model

DECIS supports any linear dependency model, i.e., the outcomes of an uncertain parameter in the linear program are a linear function of a number of independent random parameter outcomes. DECIS considers only discrete distributions: you must approximate any continuous distributions by discrete ones. The number of possible realizations of the discrete random parameters determines the accuracy of the approximation. A special case of a linear dependency model arises when you have only independent random parameters in your model. In this case the independent random parameters are mapped one to one into the random parameters of the stochastic program. We will present the independent case first and then expand to the case with linear dependency. According to setting up a linear dependency model we present the formulation in GAMS by first defining independent random parameters and then defining the distributions of the uncertain parameters in your model.

5.17.2.4.1 Specifying Independent Random Parameters There are of course many different ways you can set up independent random parameters in GAMS. In the following we show one possible way that is generic and thus can be adapted for different models. The set-up uses the set `stoch` for labeling outcome named "out" and probability named "pro" of each independent random parameter. In the following we show how to define an independent random parameter, say, `v1`. The formulation uses the set `omega1` as driving set, where the set contains one element for each possible realization the random parameter can assume. For example, the set `omega1` has four elements according to a discrete distribution of four possible outcomes. The distribution of the random parameter is defined as the parameter `v1`, a two-dimensional array of outcomes "out" and corresponding probability "pro" for each of the possible

realizations of the set `omega1`, "o11", "o12", "o13", and "o14". For example, the random parameter `v1` has outcomes of $-1.0, -0.9, -0.5, -0.1$ with probabilities $0.2, 0.3, 0.4, 0.1$, respectively. Instead of using assignment statements for inputting the different realizations and corresponding probabilities you could also use the table statement. Always make sure that the sum of the probabilities of each independent random parameter adds to one.

```
* defining independent stochastic parameters
set stoch /out, pro /;
set omega1 / o11, o12, o13, o14 /;

table v1(stoch, omega1)
      o11  o12  o13  o14
out   -1.0 -0.9 -0.5 -0.1
pro    0.2  0.3  0.4  0.1
;
```

Random parameter `v1` is the first out of five independent random parameters of the illustrative model APL1P, where the first two represent the independent availabilities of the generators `g1` and `g2` and the latter three represent the independent demands of the demand levels `h`, `m`, and `l`. We also represent the definitions of the remaining four independent random parameters. Note that random parameters `v3`, `v4`, and `v5` are identically distributed.

```
set omega2 / o21, o22, o23, o24, o25 /;
table v2(stoch, omega2)
      o21  o22  o23  o24  o25
out   -1.0 -0.9 -0.7 -0.1 -0.0
pro    0.1  0.2  0.5  0.1  0.1
;
```

```
set omega3 / o31, o32, o33, o34 /;
table v3(stoch, omega1)
      o11  o12  o13  o14
out    900 1000 1100 1200
pro   0.15 0.45 0.25 0.15
;
```

```
set omega4 / o41, o42, o43, o44 /;
table v4(stoch, omega1)
      o11  o12  o13  o14
out    900 1000 1100 1200
pro   0.15 0.45 0.25 0.15
;
```

```
set omega5 / o51, o52, o53, o54 /;
table v5(stoch, omega1)
      o11  o12  o13  o14
out    900 1000 1100 1200
pro   0.15 0.45 0.25 0.15
;
```

5.17.2.4.2 Defining the Distributions of the Uncertain Parameters in the Model Having defined the independent stochastic parameters (you may copy the setup above and adapt it for your model), we next define the stochastic parameters in the GAMS model. The stochastic parameters of the

model are defined by writing a file, the GAMS stochastic file, using the put facility of GAMS. The GAMS stochastic file resembles closely the stochastic file of the SMPS input format. The main difference is that we use the row, column, bounds, and right hand side names of the GAMS model and that we can write it in free format.

Independent Stochastic Parameters

First we describe the case where all stochastic parameters in the model are independent, see below the representation of the stochastic parameters for the illustrative example APL1P, which has five independent stochastic parameters.

First define the GAMS stochastic file "MODEL.STG" (only the exact name in uppercase letters is supported) and set up GAMS to write to it. This is done by the first two statements. You may want to consult the GAMS manual for how to use put for writing files. The next statement "INDEP DISCRETE" indicates that a section of independent stochastic parameters follows. We then write all possible outcomes and corresponding probabilities for each stochastic parameter by using loop statements. Of course one could also write each line separately, but the loops work nicely. Writing a "*" between the definitions of the independent stochastic parameters is merely for optical reasons and can be omitted.

```
* defining distributions (writing file MODEL.STG)
file stg /MODEL.STG/;
put stg;

put "INDEP DISCRETE" /;
loop(omega1,
put "x g1  omax g1  ", v1("out", omega1), " period2 ", v1("pro", omega1) /;
);
put "*" /;
loop(omega2,
put "x g2  omax g2  ", v2("out", omega2), " period2 ", v2("pro", omega2) /;
);
put "*" /;
loop(omega3,
put "RHS  demand h  ", v3("out", omega3), " period2 ", v3("pro", omega3) /;
);
put "*" /;
loop(omega4,
put "RHS  demand m  ", v4("out", omega4), " period2 ", v4("pro", omega4) /;
);
put "*" /;
loop(omega5,
put "RHS  demand l  ", v5("out", omega5), " period2 ", v5("pro", omega5) /;
);
putclose stg;
```

In the example APL1P the first stochastic parameter is the availability of generator g1. In the model the parameter appears as the coefficient of variable x(g1) in equation omax(g1). The definition using the put statement first gives the stochastic parameter as the intersection of variable x(g1) with equation omax(g1), but without having to type the braces, thus *x g1 omax g1*, then the outcome *v1("out", omega1)* and the probability *v1("pro", omega1)* separated by "period2". The different elements of the statement must be separated by blanks. Since the outcomes and probabilities of the first stochastic parameters are driven by the set omega1 we loop over all elements of the set omega1. We continue and define all possible outcomes for each of the five independent stochastic parameters.

In the example of independent stochastic parameters, the specification of the distribution of the stochastic parameters using the put facility creates the following file "MODEL.STG", which then is processed by the GAMS/DECIS interface:

```

INDEP DISCRETE
x g1 omax g1      -1.00 period2      0.20
x g1 omax g1      -0.90 period2      0.30
x g1 omax g1      -0.50 period2      0.40
x g1 omax g1      -0.10 period2      0.10
*
x g2 omax g2      -1.00 period2      0.10
x g2 omax g2      -0.90 period2      0.20
x g2 omax g2      -0.70 period2      0.50
x g2 omax g2      -0.10 period2      0.10
x g2 omax g2       0.00 period2      0.10
*
RHS demand h      900.00 period2      0.15
RHS demand h     1000.00 period2      0.45
RHS demand h     1100.00 period2      0.25
RHS demand h     1200.00 period2      0.15
*
RHS demand m      900.00 period2      0.15
RHS demand m     1000.00 period2      0.45
RHS demand m     1100.00 period2      0.25
RHS demand m     1200.00 period2      0.15
*
RHS demand l      900.00 period2      0.15
RHS demand l     1000.00 period2      0.45
RHS demand l     1100.00 period2      0.25
RHS demand l     1200.00 period2      0.15

```

For defining stochastic parameters in the right-hand side of the model use the keyword *RHS* as the column name, and the equation name of the equation which right-hand side is uncertain, see for example the specification of the uncertain demands *RHS demand h*, *RHS demand m*, and *RHS demand l*. For defining uncertain bound parameters you would use the keywords *UP*, *LO*, or *FX*, the string *bnd*, and the variable name of the variable whose upper, lower, or fixed bound is uncertain.

Note all the keywords for the definitions are in capital letters, i.e., "INDEP DISCRETE", "RHS", and not represented in the example "UP", "LO", and "FX".

Note that in GAMS equations, variables may appear in the right-hand side, e.g. "EQ.. X+1 =L= 2*Y". When the coefficient 2 is a random variable, we need to be aware that GAMS will generate the following LP row $X - 2*Y =L= -1$. Suppose the probability distribution of this random variable is given by:

```

set s scenario /pessimistic, average, optimistic/;
parameter outcome(s) / pessimistic 1.5
                        average      2.0
                        optimistic  2.3 /;
parameter prob(s)     / pessimistic 0.2
                        average      0.6
                        optimistic  0.2 /;

```

then the correct way of generating the entries in the stochastic file would be:

```

loop(s,
  put  "Y EQ ",(-outcome(s))," PERIOD2 ",prob(s)/;
);

```

Note the negation of the outcome parameter. Also note that expressions in a PUT statement have to be surrounded by parentheses. GAMS reports in the *row listing* section of the listing file how equations are generated. You are encouraged to inspect the row listing to discover or confirm how coefficients appear in a generated LP row.

5.17.2.4.3 Dependent Stochastic Parameters Next we describe the case of general linear dependency of the stochastic parameters in the model, see below the representation of the stochastic parameters for the illustrative example APL1PCA, which has three dependent stochastic demands driven by two independent stochastic random parameters. First we give the definition of the two independent stochastic parameters, which in the example happen to have two outcomes each.

```
* defining independent stochastic parameters
set stoch /out, pro/;

set omega1 / o11, o12 /;
table v1(stoch,omega1)
      o11 o12
out    2.1 1.0
pro    0.5 0.5 ;

set omega2 / o21, o22 /;
table v2(stoch, omega2)
      o21 o22
out    2.0 1.0
pro    0.2 0.8 ;
```

We next define the parameters of the transition matrix from the independent stochastic parameters to the dependent stochastic parameters of the model. We do this by defining two parameter vectors, where the vector *hm1* gives the coefficients of the independent random parameter *v1* in each of the three demand levels and the vector *hm2* gives the coefficients of the independent random parameter *v2* in each of the three demand levels.

```
parameter hm1(dl) / h 300., m 400., l 200. /;
parameter hm2(dl) / h 100., m 150., l 300. /;
```

Again first define the GAMS stochastic file "MODEL.STG" and set GAMS to write to it. The statement *BLOCKS DISCRETE* indicates that a section of linear dependent stochastic parameters follows.

```
* defining distributions (writing file MODEL.STG)
file stg / MODEL.STG /;
put stg;

put "BLOCKS DISCRETE" /;
scalar h1;
loop(omega1,
put "BL v1 period2 ", v1("pro", omega1)/;
loop(dl,
h1 = hm1(dl) * v1("out", omega1);
put "RHS demand ", dl.tl:1, " ", h1/;
);
);
loop(omega2,
put " BL v2 period2 ", v2("pro", omega2) /;
loop(dl,
h1 = hm2(dl) * v2("out", omega2);
put "RHS demand ", dl.tl:1, " ", h1/;
);
);
putclose stg;
```

Dependent stochastic parameters are defined as functions of independent random parameters. The keyword *BL* labels a possible realization of an independent random parameter. The name besides the *BL* keyword is used to distinguish between different outcomes of the same independent random parameter or a different one. While you could use any unique names for the independent random parameters, it appears natural to use the names you have already defined above, e.g., *v1* and *v2*. For each realization of each independent random parameter define the outcome of every dependent random parameter (as a function of the independent one). If a dependent random parameter in the GAMS model depends on two or more different independent random parameters the contributions of each of the independent parameters are added. We are therefore in the position to model any linear dependency model. (Note that the class of models that can be accommodated here is more general than linear. The functions, with which an independent random variable contributes to the dependent random variables can be any ones in one argument. As a general rule, any stochastic model that can be estimated by linear regression is supported by GAMS/DECIS.)

Define each independent random parameter outcome and the probability associated with it. For example, the statement starting with *BL v1 period2* indicates that an outcome of (independent random parameter) *v1* is being defined. The name *period2* indicates that it is a second-stage random parameter, and *v1("pro", omega1)* gives the probability associated with this outcome. Next list all random parameters dependent on the independent random parameter outcome just defined. Define the dependent stochastic parameter coefficients by the GAMS variable name and equation name, or "RHS" and variable name, together with the value of the parameter associated with this realization. In the example, we have three dependent demands. Using the scalar *h1* for intermediately storing the results of the calculation, looping over the different demand levels *dl* we calculate $h1 = hm1(dl) * v1("out", omega1)$ and define the dependent random parameters as the right-hand sides of equation *demand(dl)*.

When defining an independent random parameter outcome, if the block name is the same as the previous one (e.g., when *BL v1* appears the second time), a different outcome of the same independent random parameter is being defined, while a different block name (e.g., when *BL v2* appears the first time) indicates that the first outcome of a different independent random parameter is being defined. You must ensure that the probabilities of the different outcomes of each of the independent random parameters add up to one. The loop over all elements of *omega1* defines all realizations of the independent random parameter *v1* and the loop over all elements of *omega2* defines all realizations of the independent random parameter *v2*.

Note that for the first realization of an independent random parameter, you *must* define all dependent parameters and their realizations. The values entered serve as a base case. For any other realization of an independent random parameter you only need to define the dependent parameters that have different coefficients than have been defined in the base case. For those not defined in a particular realization, their values of the base case are automatically added.

In the example of dependent stochastic parameters above, the specification of the distribution of the stochastic parameters using the put facility creates the following file "MODEL.STG", which then is processed by the GAMS/DECIS interface:

```
BLOCKS DISCRETE
BL v1 period2          0.50
RHS demand h          630.00
RHS demand m          840.00
RHS demand l          420.00
BL v1 period2          0.50
RHS demand h          300.00
RHS demand m          400.00
RHS demand l          200.00
BL v2 period2          0.20
RHS demand h          200.00
RHS demand m          300.00
RHS demand l          600.00
BL v2 period2          0.80
RHS demand h          100.00
RHS demand m          150.00
RHS demand l          300.00
```

Again all the keywords for the definitions are in capital letters, i.e., "BLOCKS DISCRETE", "BL", "RHS", and not represented in the example "UP", "LO", and "FX".

Note that you can only define random parameter coefficients that are nonzero in your GAMS model. When setting up the deterministic core model put a nonzero entry as a placeholder for any coefficient that you wish to specify as a stochastic parameter. Specifying a random parameter at the location of a zero coefficient in the GAMS model causes DECIS to terminate with an error message.

5.17.2.5 Setting DECIS as the Optimizer

After having finished the stochastic definitions you must set DECIS as the optimizer. This is done by issuing the following statements:

```
* setting DECIS as optimizer
* DECISM uses MINOS, DECISC uses CPLEX
option lp=decism;
apl1p.optfile = 1;
```

The statement *option lp = decism* sets DECIS with the MINOS LP engine as the optimizer to be used for solving the stochastic problem. Note that if you do not use DECIS, but instead use any other linear programming optimizer, your GAMS model will still run and optimize the deterministic core model that you have specified. The statement *apl1p.optfile = 1* directs GAMS to process the file DECIS.OPT, in which you may define any DECIS parameters.

5.17.2.5.1 Setting Parameter Options in the GAMS Model The options iteration limit and resource limit can be set directly in your GAMS model file. For example, the following statements

```
option iterlim = 1000;
option reslim = 6000;
```

limit the number of decomposition iterations to be less than or equal to 1000, and the elapsed time for running DECIS to be less than or equal to 6000 seconds or 100 minutes.

5.17.2.5.2 Setting Parameters in the DECIS Options File In the DECIS options file you can specify parameters regarding the solution algorithm used and control the output of the DECIS program. There is a record for each parameter you want to specify. Each record consists of the value of the parameter you want to specify and the keyword identifying the parameter, separated by a blank character or a comma. You may specify parameters with the following keywords: *istrat*, *nsamples*, *nzrows*, *iwrite*, *ibug*, *iscratch*, *ireg*, *rho*, *tolben*, and *tolw* in any order. Each keyword can be specified in lower case or upper case text in the format (A10). Since DECIS reads the records in free format you don't have to worry about the format, but some computers require that the text is inputted in quotes. Parameters that are not specified in the parameter file automatically assume their default values. See details of these parameters from Section [Description of GAMS/DECIS Options](#).

5.17.2.5.3 Example In the following example the parameters *istrat* = 7, *nsamples* = 200, and *nzrows* = 200 are specified. All other parameters are set at their default values. DECIS first solves the expected value problem and then the stochastic problem using crude Monte Carlo sampling with a sample size of *nsamples* = 200. DECIS reserves space for a maximum of *nzrows* = 50 cuts.

```
7      "ISTRAT"
200    "NSAMPLES"
50     "NZROWS"
```

5.17.2.5.4 Setting MINOS Parameters in the MINOS Specification File When you use MINOS as the optimizer for solving the master and the subproblems, you must specify optimization parameters in the MINOS specification file "MINOS.SPC". Each record of the file corresponds to the specification of one parameter and consists of a keyword and the value of the parameter in free format. Records having a "*" as their first character are considered as comment lines and are not further processed. For a detailed description of these parameters, see the MINOS Users' Guide (Murtagh and Saunders (1983) [187] . The following parameters should be specified with some consideration:

- **AIJ TOLERANCE** — Specifies the nonzero tolerance for constraint matrix elements of the problem. Matrix elements a_{ij} that have a value for which $|a_{ij}|$ is less than "AIJ TOLERANCE" are considered by MINOS as zero and are automatically eliminated from the problem. It is wise to specify "AIJ TOLERANCE 0.0 "
- **SCALE** — Specifies MINOS to scale the problem ("SCALE YES") or not ("SCALE NO"). It is wise to specify "SCALE NO".
- **ROWS** — Specifies the number of rows in order for MINOS to reserve the appropriate space in its data structures when reading the problem. "ROWS" should be specified as the number of constraints in the core problem or greater.
- **COLUMNS** — Specifies the number of columns in order for MINOS to reserve the appropriate space in its data structures when reading the problem. "COLUMNS" should be specified as the number of variables in the core problem or greater.
- **ELEMENTS** — Specifies the number of nonzero matrix coefficients in order for MINOS to reserve the appropriate space in its data structures when reading the problem. "ELEMENTS" should be specified as the number of nonzero matrix coefficients in the core problem or greater.

5.17.2.5.5 Example The following example represents typical specifications for running DECIS with MINOS as the optimizer.

```
BEGIN SPECS
PRINT LEVEL           1
LOG FREQUENCY         10
SUMMARY FREQUENCY     10
MPS FILE              12
ROWS                  20000
COLUMNS              50000
ELEMENTS              100000
ITERATIONS LIMIT      30000
*
FACTORIZATION FREQUENCY 100
AIJ TOLERANCE          0.0
*
SCALE                 NO
END OF SPECS
```

5.17.2.5.6 Setting CPLEX Parameters Using System Environment Variables When you use CPLEX as the optimizer for solving the master and the subproblems, optimization parameters must be specified through system environment variables. You can specify the parameters "CPLEXLICDIR", "SCALELP", "NOPRESOLVE", "ITERLOG", "OPTIMALITYTOL", "FEASIBILITYTOL", and "DUALSIMPLEX".

- **CPLEXLICDIR** — Contains the path to the CPLEX license directory. For example, on a Unix system with the CPLEX license directory in /usr/users/cplex/cplexlicdir you issue the command *setenv CPLEXLICDIR /usr/users/cplex/cplexlicdir*.

- **SCALELP** — Specifies CPLEX to scale the master and subproblems before solving them. If the environment variable is not set no scaling is used. Setting the environment variable, e.g., by issuing the command *setenv SCALELP yes*, scaling is switched on.
- **NOPRESOLVE** — Allows to switch off CPLEX's presolver. If the environment variable is not set, presolve will be used. Setting the environment variable, e.g., by setting *setenv NOPRESOLVE yes*, no presolve will be used.
- **ITERLOG** — Specifies the iteration log of the CPLEX iterations to be printed to the file "MODEL.CPX". If you do not set the environment variable no iteration log will be printed. Setting the environment variable, e.g., by setting *setenv ITERLOG yes*, the CPLEX iteration log is printed.
- **OPTIMALITYTOL** — Specifies the optimality tolerance for the CPLEX optimizer. If you do not set the environment variable the CPLEX default values are used. For example, setting *setenv OPTIMALITYTOL 1.0E-7* sets the CPLEX optimality tolerance to 0.0000001.
- **FEASIBILITYTOL** — Specifies the feasibility tolerance for the CPLEX optimizer. If you do not set the environment variable the CPLEX default values are used. For example, setting *setenv FEASIBILITYTOL 1.0E-7* sets the CPLEX optimality tolerance to 0.0000001.
- **DUALSIMPLEX** — Specifies the dual simplex algorithm of CPLEX to be used. If the environment variable is not set the primal simplex algorithm will be used. This is the default and works beautifully for most problems. If the environment variable is set, e.g., by setting *setenv DUALSIMPLEX yes*, CPLEX uses the dual simplex algorithm for solving both master and subproblems.

5.17.2.6 GAMS/DECIS Output

After successfully having solved a problem, DECIS returns the objective, the optimal primal and optimal dual solution, the status of variables (if basic or not), and the status of equations (if binding or not) to GAMS. In the case of first-stage variables and equations you have all information available in GAMS, as you would with any other solver, but instead of obtaining the optimal values for a deterministic core problem you actually have the optimal values for the stochastic problem. However, for second-stage variables and constraints the expected values of the optimal primal and optimal dual solution are reported. This saves space and is useful for the calculation of risk measures. However, the information as to what the optimal primal and dual solutions were in the different scenarios of the stochastic programs is not reported back to GAMS. In a future release of the GAMS/DECIS interface the GAMS language is planned to be extended to handle the scenario second-stage optimal primal and dual values at least for selected variables and equations.

While running, DECIS outputs important information about the progress of the execution to your computer screen. After successfully solving a problem, DECIS also outputs its optimal solution to the solution output file "MODEL.SOL". The debug output file "MODEL.SCR" contains important information about the optimization run, and the optimizer output files "MODEL.MO" (when using DECIS with MINOS) or "MODEL.CPX" (when using DECIS with CPLEX) contain solution output from the optimizer used. In the DECIS User's Guide you find a detailed discussion of how to interpret the screen output, the solution report and the information in the output files.

5.17.2.6.1 The Screen Output The output to the screen allows you to observe the progress of a DECIS run. After the program logo and the copyright statement, you see four columns of output being written to the screen as long as the program proceeds. The first column (from left to right) represents the iteration count, the second column the lower bound (the optimal objective of the master problem), the third column the best upper bound (exact value or estimate of the total expected cost of the best solution found so far), and the fourth column the current upper bound (exact value or estimate of the total expected cost of current solution). After successful completion, DECIS quits with "Normal Exit", otherwise, if an error has been encountered, the program stops with the message "Error Exit".

5.17.2.6.2 Example When solving the illustrative example APL1P using strategy 5, we obtain the following report on the screen:

```

```

Normal Exit

5.17.2.6.3 The Solution Output File The solution output file contains the solution report from the DECIS run. Its name is "MODEL.SOL". The file contains the best objective function value found, the corresponding values of the first-stage variables, the corresponding optimal second-stage cost, and a lower and an upper bound on the optimal objective of the problem. In addition, the number of universe scenarios and the settings for the stopping tolerance are reported. In the case of using a deterministic strategy for solving the problem, exact values are reported. When using Monte Carlo sampling, estimated values, their variances, and the sample size used for the estimation are reported. Instead of exact upper and lower bounds, probabilistic upper and lower bounds, and a 95% confidence interval, within which the true optimal solution lies with 95% confidence, are reported. A detailed description of the solution output file can be found in the DECIS User's Guide.

5.17.2.6.4 The Debug Output File The debug output file contains the standard output of a run of DECIS containing important information about the problem, its parameters, and its solution. It also contains any error messages that may occur during a run of DECIS. In the case that DECIS does not complete a run successfully, the cause of the trouble can usually be located using the information in the debug output file. If the standard output does not give enough information you can set the debug parameter [ibug](#) in the parameter input file to a higher value and obtain additional debug output. A detailed description of the debug output file can be found in the DECIS User's Guide.

5.17.2.6.5 The Optimizer Output Files The optimizer output file "MODEL.MO" contains all the output from MINOS when called as a subroutine by DECIS. You can specify what degree of detail should be outputted by setting the appropriate "PRINT LEVEL" in the MINOS specification file. The optimizer output file "MODEL.CPX" reports messages and the iteration log (if switchwd on using the environment variable) from CPLEX when solving master and sub problems.

5.17.3 Description of GAMS/DECIS Options

5.17.3.1 DECIS Solver Options

Option	Description	Default
IBug	Debug output	0
IReg	Indicator for regularized decomposition - MINOS only	0
IScratch	Internal unit number for output and debug	17
IStrat	Defines the solution strategy used	3
IWrite	Subproblem output	0
NSamples	Sample size used for the estimation	100
NZRows	Number of rows reserved for cuts in the master problem	100
Rho	rho parameter of regularization term in the objective function	1000
TolBen	Tolerance for stopping the decomposition algorithm	1e-7
TolW	tolerance when writing debug solution output	1e-9

5.17.3.2 DECIS EMP SP Options

Option	Description	Default
EVSubSolver	Subsolver to run on expected value problem	auto
EVSubSolverOpt	Optfile value to pass to the subsolver for expected value problem	0
FileName	Filename of generated scalar GAMS model	auto
ScenarioLog	Select log option for scenario solves	0
SolveEVProb	Solve and report the expected value solution	
SolveScenarios	Maximum number of scenarios solved	100
SubSolvePar	User defined GAMS parameters for subsolve	
SubSolver	Subsolver to run	decisc
Terminate	Generate the GAMS source code of the reformulated Model	

EVSubSolver (*string*): Subsolver to run on expected value problem ↩

Also controls solver used for individual scenarios.

Default: auto

EVSubSolverOpt (*integer*): Optfile value to pass to the subsolver for expected value problem ↩

Range: [0, 999]

Default: 0

FileName (*string*): Filename of generated scalar GAMS model ↩

Default: `auto`

IBug (*integer*): Debug output ↩

Default: 0

value	meaning
0	DECIS does not write any debug output
1	Solution of the master problem on each iteration
2	Value 1 plus scenario index and the optimal objective value for each subproblem solved
3	Value 2 plus information regarding importance sampling
4	Value 3 plus optimal dual variables of the cuts
5	Value 4 plus coefficients and the right-hand side of the cuts
6	Value 5 plus dump of the master problem and the subproblem in MPS format

IReg (*boolean*): Indicator for regularized decomposition - MINOS only ↔

Default: 0

IScratch (*integer*): Internal unit number for output and debug ↔

Range: $[1, \infty]$

Default: 17

IStrat (*integer*): Defines the solution strategy used ↔

Default: 3

value	meaning
1	Solves the expected value problem
2	Solves the stochastic problem using Monte Carlo importance sampling
3	Refers to istrat = 1 plus istrat = 2
4	Solves the stochastic universe problem
5	Refers to istrat = 1 plus istrat = 4
6	Solves the stochastic problem using crude Monte Carlo sampling
7	Refers to istrat = 1 plus istrat = 6
8	Solves the stochastic problem using Monte Carlo pre-sampling
9	Refers to istrat = 1 plus istrat = 8
10	Solves the stochastic problem using control variates
11	Refers to istrat = 1 plus istrat = 10

IWrite (*integer*): Subproblem output ↔

Default: 0

value	meaning
0	No optimizer output is written
1	Optimizer output is written to the file

NSamples (*integer*): Sample size used for the estimation ↔

Range: $[30, \infty]$

Default: 100

NZRows (*integer*): Number of rows reserved for cuts in the master problem [↔](#)

Range: $[1, \infty]$

Default: 100

Rho (*real*): rho parameter of regularization term in the objective function [↔](#)

Default: 1000

ScenarioLog (*integer*): Select log option for scenario solves [↔](#)

Default: 0

value	meaning
0	Quiet
1	Summary
2	Full log

SolveEVProb (*no value*): Solve and report the expected value solution [↔](#)

SolveScenarios (*integer*): Maximum number of scenarios solved [↔](#)

Default: 100

SubSolvePar (*string*): User defined GAMS parameters for subsolve [↔](#)

SubSolver (*string*): Subsolver to run [↔](#)

Default: `decisc`

value	meaning
<code>decisc</code>	Decis using Cplex
<code>decism</code>	Decis using Minos

Terminate (*no value*): Generate the GAMS source code of the reformulated Model [↔](#)

TolBen (*real*): Tolerance for stopping the decomposition algorithm [↔](#)

Default: `1e-7`

TolW (*real*): tolerance when writing debug solution output [↔](#)

Default: `1e-9`

5.17.4 Appendix A - GAMS/DECIS Illustrative Examples

5.17.4.1 Example APL1P

```

*   APL1P test model

5.17.5 Appendix B - Error Messages

1. **ERROR in MODEL.STO: kwd, word1, word2 was not matched in first realization of block**
The specification of the stochastic parameters is incorrect. The stochastic parameter has not been specified in the specification of the first outcome of the block. When specifying the first outcome of a block always include all stochastic parameters corresponding to the block.
 2. **Option word1 word2 not supported**
You specified an input distribution in the stochastic file that is not supported. Check the DECIS manual for supported distributions.
 3. **Error in time file**
The time file is not correct. Check the file MODEL.TIM. Check the DECIS manual for the form of the time file.
 4. **ERROR in MODEL.STO: stochastic RHS for objective, row name2**
The specification in the stochastic file is incorrect. You attempted to specify a stochastic right-hand side for the objective row (row name2). Check file MODEL.STO.
 5. **ERROR in MODEL.STO: stochastic RHS in master, row name2**
The specification in the stochastic file is incorrect. You attempted to specify a stochastic right-hand side for the master problem (row name2). Check file MODEL.STO.
 6. **ERROR in MODEL.STO: col not found, name1**
The specification in the stochastic file is incorrect. The entry in the stochastic file, name1, is not found in the core file. Check file MODEL.STO.
 7. **ERROR in MODEL.STO: invalid col/row combination, (name1/name2)**
The stochastic file (MODEL.STO) contains an incorrect specification.
 8. **ERROR in MODEL.STO: no nonzero found (in B or D matrix) for col/row (name1, name2)**
There is no nonzero entry for the combination of name1 (col) and name2(row) in the B-matrix or in the D-matrix. Check the corresponding entry in the stochastic file (MODEL.STO). You may want to include a nonzero coefficient for (col/row) in the core file (MODEL.COR).
 9. **ERROR in MODEL.STO: col not found, name2**
The column name you specified in the stochastic file (MODEL.STO) does not exist in the core file (MODEL.COR). Check the file MODEL.STO.
 10. **ERROR in MODEL.STO: stochastic bound in master, col name2**
You specified a stochastic bound on first-stage variable name2. Check file MODEL.STO.
 11. **ERROR in MODEL.STO: invalid bound type (kwd) for col name2**
The bound type, kwd, you specified is invalid. Check file MODEL.STO.
 12. **ERROR in MODEL.STO: row not found, name2**
The specification in the stochastic file is incorrect. The row name, name2, does not exist in the core file. Check file MODEL.STO.
 13. **ERROR: problem infeasible**
The problem solved (master- or subproblem) turned out to be infeasible. If a subproblem is infeasible, you did not specify the problem as having the property of "complete recourse". Complete recourse means that whatever first-stage decision is passed to a subproblem, the subproblem will have a feasible solution. It is the best way to specify a problem, especially if you use a sampling based solution strategy. If DECIS encounters a feasible subproblem, it adds a feasibility cut and continues the execution. If DECIS encounters an infeasible master problem, the problem you specified is infeasible, and DECIS terminates. Check the problem formulation.
 14. **ERROR: problem unbounded**
The problem solved (master- or subproblem) turned out to be unbounded. Check the problem formulation.
-

15. ERROR: error code: inform
The solver returned with an error code from solving the problem (master- or subproblem). Consult the users' manual of the solver (MINOS or CPLEX) for the meaning of the error code, inform. Check the problem formulation.
 16. ERROR: while reading SPECS file
The MINOS specification file (MINOS.SPC) contains an error. Check the specification file. Consult the MINOS user's manual.
 17. ERROR: reading mps file, mpsfile
The core file mpsfile (i.e., MODEL.COR) is incorrect. Consult the DECIS manual for instructions regarding the MPS format.
 18. ERROR: row 1 of problem is not a free row
The first row of the problem is not a free row (i.e., is not the objective row). In order to make the first row a free row, set the row type to be 'N'. Consult the DECIS manual for the MPS specification of the problem.
 19. ERROR: name not found = nam1, nam2
There is an error in the core file (MODEL.COR). The problem cannot be decomposed correctly. Check the core file and check the model formulation.
 20. ERROR: matrix not in staircase form
The constraint matrix of the problem as specified in core file (MODEL.COR) is not in staircase form. The first-stage rows and columns and the second-stage rows and columns are mixed within each other. Check the DECIS manual as to how to specify the core file. Check the core file and change the order of rows and columns.
-

5.17.6 DECIS License and Warranty

The software, which accompanies this license (the "**Software**") is the property of Gerd Infanger and is protected by copyright law. While Gerd Infanger continues to own the Software, you will have certain rights to use the Software after your acceptance of this license. Except as may be modified by a license addendum, which accompanies this license, your rights and obligations with respect to the use of this Software are as follows:

- You may
 1. Use one copy of the Software on a single computer,
 2. Make one copy of the Software for archival purposes, or copy the software onto the hard disk of your computer and retain the original for archival purposes,
 3. Use the Software on a network, provided that you have a licensed copy of the Software for each computer that can access the Software over that network, item After a written notice to Gerd Infanger, transfer the Software on a permanent basis to another person or entity, provided that you retain no copies of the Software and the transferee agrees to the terms of this agreement.
- You may not
 1. Copy the documentation, which accompanies the Software,
 2. Sublicense, rent or lease any portion of the Software,
 3. Reverse engineer, de-compile, disassemble, modify, translate, make any attempt to discover the source code of the Software, or create derivative works from the Software.

5.17.6.1 Limited Warranty:

Gerd Infanger warrants that the media on which the Software is distributed will be free from defects for a period of thirty (30) days from the date of delivery of the Software to you. Your sole remedy in the event of a breach of the warranty will be that Gerd Infanger will, at his option, replace any defective media returned to Gerd Infanger within the warranty period or refund the money you paid for the Software. Gerd Infanger does not warrant that the Software will meet your requirements or that operation of the Software will be uninterrupted or that the Software will be error-free.

THE ABOVE WARRANTY IS EXCLUSIVE AND IN LIEU OF ALL OTHER WARRANTIES, WHETHER EXPRESS OR IMPLIED, INCLUDING THE IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT.

5.17.6.2 Disclaimer of Damages:

REGARDLESS OF WHETHER ANY REMEDY SET FORTH HEREIN FAILS OF ITS ESSENTIAL PURPOSE, IN NO EVENT WILL GERD INFANGER BE LIABLE TO YOU FOR ANY SPECIAL, CONSEQUENTIAL, INDIRECT OR SIMILAR DAMAGES, INCLUDING ANY LOST PROFITS OR LOST DATA ARISING OUT OF THE USE OR INABILITY TO USE THE SOFTWARE EVEN IF GERD INFANGER HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

IN NO CASE SHALL GERD INFANGER'S LIABILITY EXCEED THE PURCHASE PRICE FOR THE SOFTWARE. The disclaimers and limitations set forth above will apply regardless of whether you accept the Software.

5.17.6.3 General:

This Agreement will be governed by the laws of the State of California. This Agreement may only be modified by a license addendum, which accompanies this license or by a written document, which has been signed by both you and Gerd Infanger. Should you have any questions concerning this Agreement, or if you desire to contact Gerd Infanger for any reason, please write:

5.18 DICOPT

Ignacio E. Grossmann, Jagadisan Viswanathan, Aldo Vecchiotti; Engineering Research Design Center, Carnegie Mellon University, Pittsburgh, PA

Ramesh Raman, Erwin Kalvelagen; GAMS Development Corporation, Washington D.C.

5.18.1 Introduction

DICOPT is a program for solving mixed-integer nonlinear programming (MINLP) problems that involve linear binary or integer variables and linear and nonlinear continuous variables. While the modeling and solution of MINLP optimization problems has not yet reached the stage of maturity and reliability achieved by linear, integer, or non-linear programming modeling, these problems still have rich areas of application. For example, they often arise in engineering design, management sciences, and finance. DICOPT (Discrete and Continuous OPTimizer) was developed by J. Viswanathan and Ignacio E. Grossmann at the Engineering Design Research Center (EDRC) at Carnegie Mellon University. The program is based on the extensions of the outer-approximation algorithm for the equality relaxation strategy. The MINLP algorithm inside DICOPT solves a series of NLP and MIP sub-problems. These sub-problems can be solved using any NLP (Nonlinear Programming) or MIP (Mixed-Integer Programming) solver that runs under GAMS. The performance will heavily depend on the choice of the selected subsolvers.

Although the algorithm has provisions to handle non-convexities, it does not necessarily obtain the global optimum.

The GAMS/DICOPT system has been designed with two main goals in mind:

- to build on existing modeling concepts, introduce a minimum of extensions to the existing modeling language, and provide upward compatibility to ensure easy transition from existing modeling applications to nonlinear mixed-integer formulations
 - to use existing optimizers to solve the DICOPT sub-problems. This allows one to match the best algorithms to the problem at hand and guarantees that any new development and enhancements in the NLP and MIP solvers become automatically and immediately available to DICOPT.
-

5.18.2 Requirements

In order to use DICOPT you will need to have access to a licensed GAMS BASE system as well as at least one licensed MIP solver and one licensed NLP solver. For difficult models it is advisable to also have access to multiple solvers.

5.18.3 How to Run a Model with GAMS/DICOPT

DICOPT is only able to solve MINLP and MIQCP models. If you did not specify DICOPT as the default solver you can use the following statement in your GAMS model:

```
option minlp = dicopt;
```

This should appear before the solve statement. DICOPT automatically uses the default MIP and NLP solver to solve its sub-problems. One can override this with GAMS statements like:

```
option nlp = conopt; { or any other nlp solver }
option mip = gurobi; { or any other mip solver }
```

These options can also be specified on the command line:

```
> gams mymodel minlp=dicopt nlp=conopt mip=gurobi
```

In the Integrated Development Environment (IDE) the command line option can be specified in the edit line in the right upper corner of the main window.

Possible NLP solvers include `conopt`, `ipopt`, `knitro`, `minos`, and `snopt`. Possible MIP solvers include `cplex`, `gurobi`, and `xpress`.

With an option file it is even possible to use alternate solvers in different cycles. Section [DICOPT Options](#) explains this in detail.

5.18.4 Overview of DICOPT

DICOPT solves models of the form:

$$\begin{array}{ll} \text{min or max} & f(x, y) \\ \text{subject to} & g(x, y) \sim b \\ & \ell_x \leq x \leq u_x \\ & y \in [\ell_y], \dots, [u_y] \end{array} \quad (\text{MINLP})$$

where x are the continuous variables and y are the discrete variables. The symbol $\sim$ is used to denote a vector of relational operators $\{\leq, =, \geq\}$. The constraints can be either linear or non-linear. Bounds ℓ and u on the variables are handled directly. $\lceil x \rceil$ indicates the smallest integer, greater than or equal to x . Similarly, $\lfloor x \rfloor$ indicates the largest integer, less than or equal to x . The discrete variables can be either integer variables or binary variables.

5.18.5 The Algorithm

The algorithm in DICOPT is based on three key ideas:

- Outer Approximation
- Equality Relaxation
- Augmented Penalty

Outer Approximation refers to the fact that the surface described by a convex function lies above the tangent hyper-plane at any interior point of the surface. (In 1-dimension, the analogous geometrical result is that the tangent to a convex function at an interior point lies below the curve). In the algorithm outer-approximations are attained by generating linearizations at each iterations and accumulating them in order to provide successively improved linear approximations of nonlinear convex functions that underestimate the objective function and overestimate the feasible region.

Equality Relaxation is based on the following result from non-linear programming. Suppose the MINLP problem is formulated in the form:

$$\begin{array}{ll} \text{minimize or maximize} & f(x) + c^T y \\ \text{subject to} & G(x) + Hy \sim b \\ & \ell \leq x \leq u \\ & y \in \{0, 1\} \end{array}$$

i.e. the discrete variables are binary variables and they appear linearly in the model.

Let $y^{(0)}$ be any fixed binary vector and let $x^{(0)}$ be the solution of the corresponding NLP subproblem:

$$\begin{array}{ll} \text{minimize} & c^T y^{(0)} + f(x) \\ \text{subject to} & Ay^{(0)} + h(x) = 0 \\ & By^{(0)} + g(x) \leq 0 \\ & \ell \leq x \leq u \end{array}$$

Further let

$$\begin{array}{ll} T^{(0)} &= \text{diag}(t_{i,i}) \\ t_{i,i} &= \text{sign}(\lambda_i) \end{array}$$

where λ_i is the Lagrange multiplier of the i -th equality constraint.

If f is pseudo-convex, h is quasi-convex, and g is quasi-convex, then x^0 is also the solution of the following NLP:

$$\begin{array}{ll} \text{minimize} & c^T y^{(0)} + f(x) \\ \text{subject to} & T^{(0)}(Ay^{(0)} + h(x)) \leq 0 \\ & By^{(0)} + g(x) \leq 0 \\ & \ell \leq x \leq u \end{array}$$

In colloquial terms, under certain assumptions concerning the convexity of the nonlinear functions, an equality constraint can be **relaxed** to be an inequality constraint. This property is used in the MIP master problem to accumulate linear approximations.

Augmented Penalty refers to the introduction of (non-negative) slack variables on the right hand sides of the just described inequality constraints and the modification of the objective function when assumptions concerning convexity do not hold.

The algorithm underlying DICOPT starts by solving the NLP in which the 0-1 conditions on the binary variables are relaxed. If the solution to this problem yields an integer solution the search stops. Otherwise, it continues with an alternating sequence of nonlinear programs (NLP) called subproblems and mixed-integer linear programs (MIP) called master problems. The NLP subproblems are solved for fixed 0-1 variables that are predicted by the MIP master problem at each (major) iteration. For convex problems the master problem also provides a lower bound on the objective function. This lower bound (in the case of minimization) increases monotonically as iterations proceed due to the accumulation of linear approximations. Note that in the case of maximization this bound is an upper bound which can be used as a stopping criterion through a DICOPT option `stop 1` (see section [DICOPT Options](#)). Another stopping criterion that tends to work very well for non-convex problems (and even for convex problems) is based on the heuristic: stop as soon as the NLP subproblems start worsening (i.e. the current NLP subproblem has an optimal objective function that is worse than the previous NLP subproblem). This stopping criterion relies on the use of the augmented penalty, and is used in the description of the algorithm below. This is also the default stopping criterion in the implementation of DICOPT. The algorithm can be stated briefly as follows:

1. Solve the NLP relaxation of the MINLP program. If $y^{(0)} = y$ is integer, stop(`integer optimum found`). Else continue with step 2.
2. Find an integer point $y^{(1)}$ with an MIP master problem that features an augmented penalty function to find the minimum over the convex hull determined by the half-spaces at the solution $(x^{(0)}, y^{(0)})$.
3. Fix the binary variables $y = y^{(1)}$ and solve the resulting NLP. Let $(x^{(1)}, y^{(1)})$ be the corresponding solution.
4. Find an integer solution $y^{(2)}$ with a MIP master problem that corresponds to the minimization over the intersection of the convex hulls described by the half-spaces of the KKT points at $y^{(0)}$ and $y^{(1)}$.
5. Repeat steps 3 and 4 until there is an increase in the value of the NLP objective function. (Repeating step 4 means augmenting the set over which the minimization is performed with additional linearizations - i.e. half-spaces - at the new KKT point).

In the MIP problems integer cuts are added to the model to exclude previously determined integer vectors $y^{(1)}, y^{(2)}, \dots, y^{(K)}$.

For a detailed description of the theory and references to earlier work, see [\[245\]](#) [\[144\]](#) [\[74\]](#) .

The algorithm has been extended to handle general integer variables and integer variables appearing nonlinearly in the model.

5.18.6 Modeling

5.18.6.1 Relaxed Model

Before solving a model with DICOPT, the user is strongly advised to experiment with the relaxed model where the integer restrictions are ignored. This is the `RMINLP` model. As the DICOPT will start solving the relaxed problem and can use an existing relaxed optimal solution, it is a good idea to solve the `RMINLP` always before attempting to solve the MINLP model, i.e., the following fragment is not detrimental with respect to performance:

```

model m /all/;
option nlp=conopt;
option mip=cplex;
option rminlp=conopt;
option minlp=dicopt;
*
* solve relaxed model
*
  solve m using rminlp minimizing z;
  abort$(m.modelstat > 2.5) "Relaxed model could not be solved";

*
* solve minlp model
*
  solve m using minlp minimizing z;

```

The second SOLVE statement will only be executed if the first SOLVE was successful, i.e., if the model status was one (optimal) or two (locally optimal).

In general it is not a good idea to try to solve an MINLP model if the relaxed model cannot be solved reliably. As the RMINLP model is a normal NLP model, some obvious points of attention are:

- **Scaling.** If a model is poorly scaled an NLP solver may not be able find the optimal or even a feasible solution. Some NLP solvers have automatic scaling algorithms, but often it is better to attack this problem on the modeling level. The GAMS scaling facility can help in this respect.
- **Starting point.** If a poor starting point is used, the NLP solver may not be able to find a feasible or optimal solution. A starting point can be set by setting level values, e.g. `X.L = 1;`. The GAMS default levels are zero, with is often not a good choice.
- **Adding bounds.** Add bounds so that all functions can be properly evaluated. If you have a function $\sqrt{x}$ or $\log(x)$ in the model, you may want to add a bound `X.L0=0.001;`. If a function like $\log(f(x))$ is used, you may want to introduce an auxiliary variable and equation $y = f(x)$ with an appropriate bound `Y.L0=0.001;`.

In some cases the relaxed problem is the most difficult model. If more than one NLP solver is available you may want to try them in a sequence:

```

model m /all/;
option nlp=conopt;
option mip=cplex;
option rminlp=conopt;
option minlp=dicopt;
*
* solve relaxed model
*
  solve m using rminlp minimizing z;
  if (m.modelstat > 2.5,
    option rminlp=minos;
    solve m using rminlp minimizing z;
  );
  if (m.modelstat > 2.5,
    option rminlp=snopt;
    solve m using rminlp minimizing z;
  );

*
* solve minlp model
*
  solve m using minlp minimizing z;

```

In this fragment we first try to solve the relaxed model using CONOPT. If that fails we try MINOS, and if that solve also fails we try SNOPT.

It is worthwhile to spend some time getting the relaxed model to solve reliably and speedily. In most cases, modeling improvements in the relaxed model, such as scaling, will also benefit the subsequent NLP sub-problems. In general these modeling improvements turn out to be rather solver independent: changes that improve the performance with CONOPT will also help solving the model with MINOS.

5.18.6.2 OPTCR and OPTCA

The DICOPT algorithm assumes that the integer sub-problems are solved to optimality. The GAMS options for OPTCR and OPTCA are therefore ignored: subproblems are solved with both tolerances set to zero. If you want to solve a MIP sub-problem with an optimality tolerance you can use the DICOPT option file to set OPTCR or OPTCA. For more information see section [DICOPT Options](#).

For models with many discrete variables, it may be necessary to introduce an OPTCR or OPTCA option in order to solve the model in acceptable time. For models with a limited number of integer variables the default to solve MIP sub-models to optimality may be acceptable.

5.18.6.3 Integer Formulations

A number of MIP formulations are not very obvious and pose a demand on the modeler's knowledge and experience. A good overview of integer programming modeling is given in [256] .

Many integer formulations use a so-called big- M construct. It is important to choose small values for those big- M numbers. As an example consider the fixed charge problem where $y_i \in \{0, 1\}$ indicate if facility i is open or closed, and where x_i is the production at facility i . Then the cost function can be modeled as:

$$\begin{aligned} C_i &= f_i y_i + v_i x_i \\ x_i &\leq M_i y_i \\ y_i &\in \{0, 1\} \\ 0 &\leq x_i \leq cap_i \end{aligned}$$

where f_i is the fixed cost and v_i the variables cost of operating a facility i . In this case the chosen M_i should be large enough that x_i is not restricted if $y_i = 1$. On the other hand, it should be as small as possible. This leads to a choice to have M_i equal to the (tight) upperbound of variable x_i (i.e. the capacity cap_i of facility i).

5.18.6.4 Non-smooth Functions

GAMS alerts NLP modelers against the use of non-smooth functions such as `min()`, `max()`, `smin()`, `smax()` and `abs()`. In order to use these functions, a non-linear program needs to be declared as a DNLP model instead of a regular NLP model:

```
option dnlp=conopt;
model m /all/;
solve m minimizing z using dnlp;
```

This construct will warn the user that problems may arise due to the use of non-smooth functions.

A possible solution is to use a smooth approximation. For instance, the function $f(x) = |x|$ can be approximated by $g(x) = \sqrt{x^2 + \varepsilon}$ for some $\varepsilon > 0$. This approximation does not contain the point $(0, 0)$. An alternative approximation can be devised that has this property:

$$f(x) \approx \frac{2x}{1 + e^{-x/h}} - x$$

MINLP models do not have such protection against non-smooth functions, but the use of such functions is just as problematic here. It is possible to use discrete variables with MINLP models in order to model if-then-else situations. For instance, in the case of the absolute value we can replace x by $x^+ - x^-$ and $|x|$ by $x^+ + x^-$ by using:

$$\begin{aligned} x &= x^+ - x^- \\ |x| &= x^+ + x^- \\ x^+ &\leq \delta M \\ x^- &\leq (1 - \delta)M \\ x^+, x^- &\geq 0 \\ \delta &\in \{0, 1\} \end{aligned}$$

where δ is a binary variable.

5.18.7 GAMS Options

GAMS options are specified in the GAMS model source, using either the `option` statement or a model suffix.

5.18.7.1 The OPTION Statement

An option statement sets a global parameter. An option statement should appear *before* the `solve` statement, as in:

```
model m /all/;
option iterlim=100;
solve m using minlp minimizing z;
```

Option statements that affect the behavior of DICOPT are listed below:

- **option domlim = n ;**

This option sets a limit on the total accumulated number of non-linear function evaluation errors that are allowed while solving the NLP subproblems or inside DICOPT itself. An example of a function evaluation error or domain error is taking the square root of a negative number. This situations can be prevented by adding proper bounds. The default is zero, i.e. no function evaluation errors are allowed.

In case a domain error occurs, the listing file will contain an appropriate message, including the equation that is causing the problem. For instance:

```
**** ERRORS(S) IN EQUATION loss(cc,sw)
      2 instance(s) of - UNDEFINED REAL POWER (RETURNED 0.0E+00)
```

If such errors appear you can increase the DOMLIM limit, but often it is better to prevent the errors from occurring in the first place. In many cases this can be accomplished by adding appropriate bounds. Sometimes extra variables and equations need to be added to accomplish this. For instance, with an expression like $\log(x - y)$, you may want to introduce a variable $z > \varepsilon$ and an equation $z = x - y$, so that the expression can be rewritten as $\log(z)$.

- **option iterlim = n ;**
This option sets a limit on the total accumulated (minor) iterations performed in the MIP and NLP subproblems.
- **option minlp = *dicopt*;**
This option selects DICOPT to solve MINLP problems.
- **option mip = s ;**
This option sets the MIP solver to be used for the MIP master problems. Note that changing from one MIP solver to another can lead to different results, and may cause DICOPT to follow a different path.
- **option nlp = s ;**
This option sets the NLP solver to be used for the NLP sub-problems. Note that changing from one NLP solver to another can lead to different results, and may cause DICOPT to follow a different path.
- **option optca = x ;**
This option is ignored. MIP master problems are solved to optimality unless specified differently in the DICOPT option file.
- **option optcr = x ;**
This option is ignored. MIP master problems are solved to optimality unless specified differently in the DICOPT option file.
- **option reslim = x ;**
This option sets a limit on the total accumulated time (in seconds) spent inside DICOPT and the subsolvers.
- **option sysout = on;**
This option will print extra information to the listing file.

In the list above (and in the following) n indicates an integer number. GAMS will also accept fractional values, which will be rounded. Options marked with an $\$x\$$ parameter expect a real number. Options with an s parameter expect a string argument.

5.18.7.2 The Model Suffix

Some options are set by assigning a value to a model suffix, as in:

```
model m /all/;
m.optfile=1;
solve m using minlp minimizing z;
```

Model suffixes that affect the behavior of DICOPT are listed below:

- **$m.dictfile = 1$;**
This option tells GAMS to write a dictionary file containing information about GAMS identifiers (equation and variables names). Such information is needed when the DICOPT option `nlptracelevel` is used, otherwise the option can be ignored.

- ***m.iterlim* = *n*;**

Sets the total accumulated (minor) iteration limit. This option overrides the global iteration limit set by an option statement, e.g.,

```
model m /all/;
m.iterlim = 100;
option iterlim = 1000;
solve m using minlp minimizing z;
```

will cause DICOPT to use an iteration limit of 100.

- ***m.optfile* = 1;**

This option instructs DICOPT to read an option file `dicopt.opt`. This file should be located in the current directory (or the project directory when using the GAMS IDE). The contents of the option file will be echoed to the listing file and to the screen (the log file):

```
--- DICOPT: Reading option file D:\MODELS\SUPPORT\DICOPT.OPT
> maxcycles 10
--- DICOPT: Starting major iteration 1
```

If the option file does not exist, the algorithm will proceed using its default settings. An appropriate message will be displayed in the listing file and in the log file:

```
--- DICOPT: Reading option file D:\MODELS\SUPPORT\DICOPT.OPT
--- DICOPT: File does not exist, using defaults...
--- DICOPT: Starting major iteration 1
```

- ***m.optfile* = *n*;**

If $n > 1$ then the option file that is read is called `dicopt.op n` (for $n = 2, \dots, 9$) or `dicopt.o n` (for $n = 10, \dots, 99$). E.g. `m.optfile=2`; will cause DICOPT to read `dicop.op2`.

- ***m.prioropt* = 1;**

This option turns on the use of priorities on the discrete variables. Priorities influence the branching order chosen by the MIP solver during solution of the MIP master problems. The use of priorities can greatly impact MIP solver performance. The priorities themselves have to be specified using the `.prior` variables suffix, e.g. `x.prior(i,j) = ord(i)`; . Contrary to intuition, variables with a lower value for their priority are branched on before variables with a higher priority, i.e., the most important variables should get lower priority values.

- ***m.reslim* = *x*;**

Sets the total accumulated time limit. This option overrides the global time limit set by an option statement.

5.18.8 DICOPT Options

This sections describes the options that can be specified in the DICOPT option file. This file is usually called `dicopt.opt`. The `optfile` model suffix must be set to tell DICOPT to read this file:

```
model m /all/;
m.optfile=1;
solve m using minlp minimizing z;
```

The option file is searched for in the current directory, or in the project directory when the IDE is used.

The option file is a standard text file, with a single option on each line. All options are case-insensitive. A line is a comment line if it starts with an asterisk, * in column one. A valid option file can look like:

```

* stop only on infeasible MIP or hitting a limit
stop 0
* use minos to solve first NLP sub problem
* and conopt for all subsequent ones
nlpsolver minos conopt

```

A convenient way to write the option file from within a GAMS model is to use the following construct:

```

$onecho > dicopt.opt
stop 0
nlpsolver minos conopt
$offecho

```

This will make the model self-contained. Notice, however, that this overwrites an existing file `dicopt.opt`.

Available DICOPT options are listed below:

5.18.8.1 Algorithmic options

Option	Description	Default
continue	How to proceed in case of NLP errors	2
convex	If enabled, the defaults for a number of other options are set to values appropriate to convex MINLPs	0
infbnd	Bound to use for unbounded integer variables in integer cuts	10000
infeasder	Use derivatives of infeasible nonlinear subproblems	0
maxcycles	Maximum number of cycles	20
relaxed	How to start DICOPT	1
solvelink	Solverlink for NLP and MIP subsolver	5
stop	Stopping criterion	2
usexinit	Use the user initial point as starting point for all NLP solves	0
weight	Penalty parameter	1000

5.18.8.2 Tolerances

Option	Description	Default
epsmip	Tolerance on test on monotonic improvement of MIP master problem	1.0e-6
epsx	Tolerance for integer values when loading relaxed solution	1.0e-3

5.18.8.3 MIP masterproblem options

Option	Description	Default
mipiterlim	List of iteration limits	

Option	Description	Default
mipoptfile	List of option files for MIP solver	
mipreslim	List of resource limits	
mipsolver	List of MIP solvers	
optca	List of OPTCA values	
optcr	List of OPTCR values	

5.18.8.4 NLP subproblem options

Option	Description	Default
domlim	List of allowed number of domain errors	
nlpiterlim	List of iteration limits	
nlpoptfile	List of option files for NLP solver	
nlpreslim	List of resource limits	
nlpsolver	List of NLP solvers	
nlptracefile	Base name of trace files	nlptrace
nlptracelevel	Trace level	0

5.18.8.5 Feasibility Pump

Option	Description	Default
feaspump	Whether to run the Feasibility Pump	0
fp_acttol	Tolerance on when to consider an equation as active	1E-6
fp_cutoffdecr	Additional relative decrement of cutoff value for the original objective function	0.1
fp_dumpsubprob	Whether to dump subproblems (NLPs and MIPs) into GAMS files	0
fp_integercuts	Whether to add integer cuts after an NLP subproblem has been solved to optimality	1
fp_iterlimit	Major Iteration limit	20
fp_mipgap	Optimality tolerance (relative gap) to use for solving MIP projection problem	0.01
fp_projcuts	Whether to add cut derived from projection of MIP solution onto NLP feasible set	1
fp_projzerotol	Tolerance on when to consider optimal value of projection problem as zero, which may trigger the solution of a Sub-NLP	1E-4
fp_sollimit	Stop when a number of (improving) solutions has been bound	maxint
fp_stalllimit	Stop when no improving solution has been bound for a number of FP iterations, -1 to disable	5
fp_subsolverlog	Whether to show the log of subsolvers	0

Option	Description	Default
<code>fp_timelimit</code>	Time limit	<code>maxdouble</code>
<code>fp_transfercuts</code>	Whether to transfer cuts from the Feasibility Pump MIP to the DICOPT MIP (all except from the round in which the FP MIP became infeasible)	1

5.18.8.6 Detailed Options Description

continue (*integer*): How to proceed in case of NLP errors ↩

This option can be used to let DICOPT continue in cases of NLP solver failure. The preferred approach is to fix the model so that NLP subproblems solve without problems. In some cases, however, (partial) failures of an NLP solver in solving the NLP subproblems can be ignored, as DICOPT may recover later on. Adding the option **continue** 0 during model debugging enables DICOPT to function in a more specific way.

Default: 2

value	meaning
0	Stop on solver failure Stop on solver failure. DICOPT will terminate when an NLP subproblem can not be solved to optimality. Some NLP solvers terminate with a status other than optimal if not all of the termination criteria are met. For instance, the change in the objective function is negligible (indicating convergence) but the reduced gradients are not within the required tolerance. Such a solution may or may not be close to the (local) optimum. Using continue 0 will prevent DICOPT from accepting such a solution.
1	Accept non-optimal feasible solutions NLP subproblem failures resulting in a non-optimal but feasible solutions are accepted. Sometimes an NLP solver cannot make further progress towards meeting all optimality conditions, although the current solution is feasible. Such a solution can be accepted by this option.
2	Ignore infeasible solutions NLP subproblem failures resulting in a non-optimal but feasible solution are accepted (as in option continue 1). NLP subproblem failures resulting in an infeasible solution are ignored. The corresponding configuration of discrete variables is forbidden to be used again. An integer cut to accomplish this is added to subsequent MIP master problems. Note that the relaxed NLP solution should be feasible. This setting is the default.

convex (*boolean*): If enabled, the defaults for a number of other options are set to values appropriate to convex MINLPs ↩

If this option is enable, the default option values will be changed such that DICOPT will stop on crossover (**stop** set to 1), linearizations from infeasible NLP subproblems will be added to the MIP master problem (**infeasder** set to 1), and the feasibility pump is run if there are no semicontinuous or semiinteger variables and no special ordered sets (**feaspump** set to 1).

Default: 0

domlim (*string*): List of allowed number of domain errors ↩

domlim $i_1 i_2 \dots i_n$. Sets a limit of the number of function and derivative evaluation errors for a particular cycle. A number of -1 means that the global GAMS option **domlim** is used. The last number i_n sets a domain error limit for all cycles $n, n+1, \dots$

Example: domlim 0 100 0

The NLP solver in the second cycle is allowed to make up to 100 evaluation errors, while all other cycles must be solved without evaluation errors.

The default is to use the global GAMS domlim option.

epsmip (*real*): Tolerance on test on monotonic improvement of MIP master problem ↩

This option can be used to relax the test on MIP objective functions. The objective function values of the MIP master problems should form a monotonic worsening curve. This is not the case if the MIP master problems are not solved to optimality. If the options OPTCR or OPTCA are set to a nonzero value, this test is bypassed. If the test fails, DICOPT will fail with a message:

The MIP solution became better after adding integer cuts. Something is wrong. Please check if your model is properly scaled. Also check your big M formulations -- the value of M should be relatively small. This error can also occur if you used a MIP solver option file with a nonzero OPTCR or OPTCA setting. In that case you may want to increase the EPSMIP setting using a DICOPT option file.

The value of

$$\frac{\text{PreviousObj} - \text{CurrentObj}}{1 + |\text{PreviousObj}|}$$

is compared against **epsmip**. In case the test fails but you want DICOPT to continue anyway, you may want to increase the value of **epsmip**. The current values used in the test (previous and current MIP objective, **epsmip**) are printed along with the above message to provide information about how much you should increase **epsmip** to pass the test. Normally, you should not have to change this value.

Default: 1.0e-6

epsx (*real*): Tolerance for integer values when loading relaxed solution ↩

This tolerance is used to distinguish integer variables that are set to an integer value by the user, or integer variables that are fractional. See the option [relaxed](#).

Default: 1.0e-3

feaspump (*integer*): Whether to run the Feasibility Pump ↩

Default: 0

value	meaning
0	Do not run the Feasibility Pump
1	Run the Feasibility Pump if there are no semicontinuous or semiinteger variables and no special ordered sets
2	Always run the Feasibility Pump

fp_acttol (*real*): Tolerance on when to consider an equation as active ↩

Default: 1E-6

fp_cutoffdecr (*real*): Additional relative decrement of cutoff value for the original objective function ↩

Default: 0.1

fp_dumpsubprob (*boolean*): Whether to dump subproblems (NLPs and MIPs) into GAMS files [↔](#)

Default: 0

fp_integercuts (*integer*): Whether to add integer cuts after an NLP subproblem has been solved to optimality [↔](#)

Default: 1

value	meaning
0	Do not use integer cuts
1	Use integer cuts only for mixed-binary problems
2	Always use integer cuts

fp_iterlimit (*integer*): Major Iteration limit [↔](#)

Default: 20

fp_mipgap (*real*): Optimality tolerance (relative gap) to use for solving MIP projection problem [↔](#)

Default: 0.01

fp_projcuts (*boolean*): Whether to add cut derived from projection of MIP solution onto NLP feasible set [↔](#)

Default: 1

fp_projzerotol (*real*): Tolerance on when to consider optimal value of projection problem as zero, which may trigger the solution of a Sub-NLP [↔](#)

Default: 1E-4

fp_sollimit (*integer*): Stop when a number of (improving) solutions has been bound [↔](#)

Default: maxint

fp_stalllimit (*integer*): Stop when no improving solution has been bound for a number of FP iterations, -1 to disable [↔](#)

Range: [-1, ∞]

Default: 5

fp_subsolverlog (*boolean*): Whether to show the log of subsolvers [↔](#)

Default: 0

fp_timelimit (*real*): Time limit [↔](#)

Default: maxdouble

fp_transfercuts (*boolean*): Whether to transfer cuts from the Feasibility Pump MIP to the DICOPT MIP (all except from the round in which the FP MIP became infeasible) [↔](#)

Default: 1

infbnd (*real*): Bound to use for unbounded integer variables in integer cuts [↔](#)

Value to use for missing bounds on discrete variables when constructing integer cuts.

Default: 10000

infeasder (*integer*): Use derivatives of infeasible nonlinear subproblems [↔](#)

This option is to determine whether linearizations of infeasible NLP subproblems are added or not added to the MIP master problem.

Default: 0

value	meaning
0	No linearizations of infeasible NLP subproblems This is the default option in which no linearizations are added in the infeasible NLP subproblems. In this case a simple integer cut is added to remove from consideration the 0-1 vector that gave rise to the infeasible NLP. Since this may slow the convergence, it is recommended to reformulate the MINLP with "elastic" constraints (i.e., adding slacks to infeasible constraints and adding a penalty for them in the objective) to ensure that the NLP subproblems are mathematically feasible.
1	Add linearization for infeasible NLP subproblems This will add linearizations derived from the infeasible NLP subproblem to the master problem. This option is recommended to speed up convergence when the MINLP is known to be convex (i.e. its continuous relaxation is convex). The possibility of cutting-off the global optimum is increased if it is used for a nonconvex MINLP.

maxcycles (*integer*): Maximum number of cycles [↔](#)

The maximum number of cycles or major iterations performed by DICOPT.

Default: 20

mipiterlim (*string*): List of iteration limits [↔](#)

`mipiterlim  $i_1$   $i_2$  ...  $i_n$` sets an iteration limit on individual MIP master problems. The last number i_n is valid for all subsequent cycles $n, n+1, \dots$. A number of -1 indicates that there is no (individual) limit on the corresponding MIP master problem. A global iteration limit is maintained through the GAMS option [iterlim](#).

Example: `mipiterlim 10000 -1`

The first MIP master problem cannot use more than 10000 iterations, while subsequent MIP master problems are not individually restricted.

Example: `mipiterlim 10000`

Sets an iteration limit of 10000 on all MIP master problems.

When this option is used it is advised to have the option `continue` set to its default of 2. The default for this option is not to restrict iteration counts on individual solves of MIP master problems. The default for this option is not to restrict iteration counts on individual solves of MIP master problems.

mipoptfile (*string*): List of option files for MIP solver [↔](#)

`mipoptfile  $s_1$   $s_2$  ...  $s_n$` specifies the option file to be used for the MIP master problems. Several option files can be specified, separated by a blank. If a digit 1 is entered the default option file for the MIP solver in question is being used. The digit 0 indicates that no option file is to be used. The last option file is also used for subsequent MIP master problems.

Example: `mipoptfile mip.opt mip2.opt 0`

This option will cause the first MIP master problem solver to read the option file `mip.opt` and the second one to read the option file `mip2.opt`; subsequent MIP master problem solvers will not use any option file.

Example: `mipoptfile 1`

This will cause the MIP solver for all MIP subproblems to read a default option file (e.g. `cplex.opt`, `xpress.opt`, `gurobi.opt` etc.).

Option files are located in the current directory (or the project directory when using the IDE). The default is not to use an option file.

mipreslim (*string*): List of resource limits ↩

`mipreslim  $x_1$   $x_2$  ...  $x_n$` sets a resource (time) limit on individual MIP master problems. The last number x_n is valid for all subsequent cycles $n, n+1, \dots$. A number -1.0 means that the corresponding MIP master problem is not individually time restricted. A global time limit is maintained through the GAMS option [reslim](#).

Example: `mipreslim -1 10000 -1`

The MIP master problem in cycle 2 cannot use more than 100 seconds, while subsequent MIP master problems are not individually restricted.

Example: `mipreslim 1000`

Sets a time limit on all MIP master problems of 1000 seconds.

When this option is used it is advised to have the option `continue` set to its default of 2. The default for this option is not to restrict individually the time a solver can spend on the MIP master problem.

mipsolver (*string*): List of MIP solvers ↩

This option specifies with MIP solver to use for the MIP master problems.

Example: `mipsolver cplex xpress`

This instructs DICOPT to use Cplex for the first MIP and XPRESS for the second and subsequent MIP problems. The last entry may be used for more than one problem.

The names to be used for the solvers are the same as one uses in the GAMS statement `OPTION MIP=...`. The default is to use the default MIP solver.

Note that changing from one MIP solver to another can lead to different results, and may cause DICOPT to follow a different path.

nlpiterlim (*string*): List of iteration limits ↩

`nlpiterlim  $i_1$   $i_2$  ...  $i_n$` sets an iteration limit on individual NLP subproblems. The last number i_n is valid for all subsequent cycles $n, n+1, \dots$. A number of -1 indicates that there is no (individual) limit on the corresponding NLP subproblem. A global iteration limit is maintained through the GAMS option [reslim](#).

Example: `nlpiterlim 1000 -1`

The first (relaxed) NLP subproblem cannot use more than 1000 iterations, while subsequent NLP subproblems are not individually restricted.

Example: `nlpiterlim 1000`

Sets an iteration limit of 1000 on all NLP subproblems.

When this option is used it is advised to have the option `continue` set to its default of 2. This default does not restrict the amount of iterations an NLP solver can spend on an NLP subproblem, other than the global iteration limit.

nlpoptfile (*string*): List of option files for NLP solver ↩

`nlpoptfile  $s_1$   $s_2$  ...  $s_n$` specifies the option file to be used for the NLP subproblems. Several option files can be specified, separated by a blank. If a digit 1 is entered, the default option file for the NLP solver in question is being used. The digit 0 indicates that no option file is to be used. The last option file is also used for subsequent NLP subproblems.

Example: `nlpoptfile nlp.opt nlp2.opt 0`

This option will cause the first NLP subproblem solver to read the option file `nlp.opt` and the second one to read the option file `nlp2.opt`; subsequent NLP subproblem solvers will not use any option file.

Example: `nlpoptfile 1`

This will cause the NLP solver for all NLP subproblems to read a default option file (e.g. `conopt.opt`, `minos.opt`, `snopt.opt` etc.).

Option files are located in the current directory (or the project directory when using the IDE). The default is not to use an option file.

nlpreslim (*string*): List of resource limits ↩

`nlpreslim  $x_1$   $x_2$  ...  $x_n$` sets a resource (time) limit on individual NLP subproblems. The last number x_n is valid for all subsequent cycles $n, n+1, \dots$. A number -1.0 means that the corresponding NLP subproblem is not individually time restricted. A global time limit is maintained through the GAMS option [reslim](#).

Example: `nlpreslim 100 -1`

The first (relaxed) NLP subproblem can not use more than 100 seconds, while subsequent NLP subproblems are not individually restricted.

Example: `nlpreslim 1000`

Sets a time limit of 1000 seconds on all NLP subproblems.

When this option is used it is advised to have the option `continue` set to its default of 2. This default does not restrict the time an NLP solver can spend on an NLP subproblem (other than the global resource limit).

nlpsolver (*string*): List of NLP solvers ↩

`nlpsolver  $s_1$   $s_2$  ...  $s_n$` . This option specifies which NLP solver to use for the NLP subproblems.

Example: `nlpsolver conopt minos snopt`

tells DICOPT to use CONOPT for the relaxed NLP, MINOS for the second NLP subproblem, and SNOPT for the third and subsequent ones. The last entry is used for more than one subproblem: for all subsequent ones DICOPT will use the last specified solver.

The names to be used for the solvers are the same as those used in the GAMS statement `OPTION NLP=...`. The default is to use the default NLP solver. Note that changing from one NLP solver to another can lead to different results, and may cause DICOPT to follow a different path.

nlptracefile (*string*): Base name of trace files ↩

Name of the files written if the option `nlptracelevel` is set. Only the stem is needed: if the name is specified as `nlptracefile nlptrace`, then files of the form `nlptrace.001`, `nlptrace.002`, etc. are written. These files contain the settings of the integer variables so that NLP subproblems can be investigated independently of DICOPT.

Default: `nlptrace`

nlptracelevel (*integer*): Trace level ↩

This sets the level for NLP tracing, which writes a file for each NLP sub-problem, so that NLP sub-problems can be investigated outside the DICOPT environment. See also the option `DICOPTnlptracefile "nlptracefile"`.

By including a trace file in your original problem and changing it into an MINLP problem, the subproblem will be solved directly by an NLP solver. This option only works if the names in the model (names of variables and equations) are exported by GAMS. This can be accomplished by using the `m.dictfile` model suffix, as in `m.dictfile=1`. In general it is more convenient to use the CONVERT solver to generate isolated NLP models (see section [Model Debugging](#)).

Default: 0

value	meaning
0	No trace info is written No trace files are written. This is the default.
1	GAMS file with fixed integer variables A GAMS file for each NLP subproblem is written which fixes the discrete variables.
2	Include levels of continuous variables As <code>nlptracelevel 1</code> , but in addition level values of the continuous variables are written.
3	Include all levels and marginals As <code>nlptracelevel 2</code> , but in addition marginal values for the equations and variables are written.

optca (*string*): List of OPTCA values ↩

`optca  $x_1$   $x_2$  ...  $x_n$` . The absolute optimality criterion for the MIP master problems. The GAMS option `optca` is ignored, as, by default, DICOPT wants to solve MIP master problems to optimality. It is possible to stop the MIP solver earlier to allow it to solve a large problem, by specifying a value for `optca` or `optcr` in a DICOPT option file. With setting a value for `optca`, the MIP solver is instructed to stop as soon as the gap between the best possible integer solution and the best found integer solution is less than x , i.e. stop as soon as

$$|\text{BestFound} - \text{BestPossible}| \leq x$$

It is possible to specify a different `optca` value for each cycle. The last number x_n is valid for all subsequent cycles $n, n+1, \dots$.

Example: `optca 10`

Stop the search in all MIP problems as soon as the absolute gap is less than 10.

Example: `optca 0 10 0`

Sets a nonzero `optca` value of 10 for cycle 2, while all other MIP master problems are solved to optimality.

The default is zero.

optcr (*string*): List of OPTCR values ↩

`optcr  $x_1$   $x_2$  ...  $x_n$` . The relative optimality criterion for the MIP master problems. The GAMS option `optcr` is ignored, as by default DICOPT wants to solve MIP master problems to optimality. To allow it to solve a large problem it is possible to stop the MIP solver earlier by specifying a value for `optca` or `optcr` in a DICOPT option file. With setting a value for `optcr`, the MIP solver is instructed to stop as soon as the relative gap between the best possible integer solution and the best found integer solution is less than x , i.e., stop as soon as

$$\frac{|\text{BestFound} - \text{BestPossible}|}{|\text{BestPossible}|} \leq x$$

Note that the relative gap cannot be evaluated if the best possible integer solution is zero. In these cases the absolute optimality criterion `optca` can be used. It is possible to specify a different `optcr` value for each cycle. The last number x_n is valid for all subsequent cycles $n, n+1, \dots$.

Example: `optcr 0.1`

Stop the search in all the MIP problems as soon as the relative gap is smaller than 10%.

Example: `optcr 0 0.01 0`

Sets a nonzero `optcr` value of 1% for cycle 2, while all other MIP master problems are solved to optimality.

The default is zero.

relaxed (*integer*): How to start DICOPT ↔

In some cases it may be possible to use a known configuration of the discrete variables. Some users have very difficult problems, where the relaxed problem cannot be solved but where NLP sub-problems with the integer variables fixed are much easier. If a reasonable integer configuration is known in advance in these cases we can bypass the relaxed NLP and tell DICOPT to directly start with this integer configuration. The integer variables need to be specified by the user before the solve statement by assigning values to the levels, as in `Y.L(I) = INITVAL(I);`.

Default: 1

value	meaning
0	Start with all integers fixed to the starting value The first NLP sub-problem will be executed with all integer variables fixed to the values specified by the user. If you don't assign a value to an integer variable, it will retain its current value, which is zero by default
1	Start with relaxed NLP The first NLP problem is the relaxed NLP problem: all integer variables are relaxed between their bounds. This is the default.
2	Start with mixture of fixed and relaxed integers The first NLP subproblem will be executed with some variables fixed and some relaxed. The program distinguishes the fixed from the relaxed variables by comparing the initial values against the bounds and the tolerance allowed <code>EPSX</code> . <code>EPSX</code> has a default value of 1.e-3. This can be changed through the option file.

solvelink (*integer*): Solvelink for NLP and MIP subsolver ↔

This option defines the solvelink used for the NLP and MIP subsolver.

Default: 5

value	meaning
1	Call NLP and MIP solver via script
2	Call NLP and MIP solver via module
5	Call NLP and MIP solver in memory

stop (*integer*): Stopping criterion ↔

This option defines the stopping criterion to be used. The search is always stopped when the (minor) iteration limit (the `iterlim` option), the resource limit (the `reslim` option), or the major iteration limit (see [maxcycles](#)) is hit or when the MIP master problem becomes infeasible.

Note: In general a higher number stops earlier, although in some cases stopping rule 2 may terminate the search earlier than rule 1. Section [Modeling](#) shows some experiments with these stopping criteria.

Default: 2

value	meaning
0	Stop on maxcycles Do not stop unless an iteration limit, resource limit, or major iteration limit is hit or an infeasible MIP master problem becomes infeasible. This option can be used to verify that DICOPT does not stop too early when using one of the other stopping rules. In general it should not be used on production runs, as in general DICOPT will often find the optimal solution using one of the more optimistic stopping rules. Do not stop unless an iteration limit, resource limit, or major iteration limit is hit or an infeasible MIP master problem becomes infeasible. This option can be used to verify that DICOPT does not stop too early when using one of the other stopping rules. In general it should not be used on production runs, as in general DICOPT will find often the optimal solution using one of the more optimistic stopping rules.
1	Stop on crossover Stop as soon as the bound defined by the objective of the last MIP master problem is worse or close (w.r.t. GAMS option <code>optcr</code>) to the best NLP solution found (a ' <code>crossover</code> ' occurred). For convex problems this gives a global solution, provided the weights are large enough and <code>optcr</code> is set to 0. This stopping criterion should only be used if it is known or it is very likely that the nonlinear functions are convex. In the case of non-convex problems the bounds of the MIP master problem are not rigorous. Therefore, the global optimum can be cut off with the setting <code>stop 1</code> .
2	Stop on worsening Stop as soon as the NLP subproblems stop improving. This ' <code>worsening</code> ' criterion is a heuristic. For non-convex problems in which valid bounds can not be obtained the heuristic often works very well. Even on convex problems, in many cases it terminates the search very early while providing an optimal or a very good integer solution. The criterion is not checked before major iteration three.
3	Stop on crossover or worsening Stop as soon as a crossover occurs or when the NLP subproblems start to worsen. (This is a combination of 1 and 2).

usexinit (*boolean*): Use the user initial point as starting point for all NLP solves ↩

Default: 0

weight (*real*): Penalty parameter ↩

The value of the penalty coefficients.

Default: 1000

5.18.9 DICOPT Output

DICOPT generates lots of output on the screen. DICOPT itself and also the NLP and MIP solvers that handle the sub-problems write messages to the screen. The most important part is the last part of the screen output.

In this section we will discuss the output DICOPT writes to the screen and the listing file using the model `procse1.gms` (this model is part of the GAMS model library). A DICOPT log is written and the reason why DICOPT terminated is explained.

```

--- DICOPT: Checking convergence
--- DICOPT: Search stopped on worsening of NLP subproblems
--- DICOPT: Log File:
Major Step Major Iter Objective Function CPU time (Sec) Iterations Evaluation Errors Solver
NLP 1 5.35021 0.05 8 0 conopt
MIP 1 2.48869 0.28 7 0 cplex
NLP 2 1.72097< 0.00 3 0 conopt
MIP 2 2.17864 0.22 10 0 cplex
NLP 3 1.92310< 0.00 3 0 conopt
MIP 3 1.42129 0.22 12 0 cplex
NLP 4 1.41100 0.00 8 0 conopt
--- DICOPT: Terminating...
--- DICOPT: Stopped on NLP worsening

The search was stopped because the objective function
of the NLP subproblems started to deteriorate.

--- DICOPT: Best integer solution found: 1.923099
--- Restarting execution
--- PROCSEL.GMS(98) 0 Mb
--- Reading solution for model process
*** Status: Normal completion

```

Notice that the integer solutions are provided by the NLP's except for major iteration one (the first NLP is the relaxed NLP). For all NLP's except the relaxed one the binary variables are fixed, according to a pattern determined by the previous MIP which operates on a linearized model. The integer solutions marked with a '<' are an improvement. We see that the NLP in cycle 4 starts to deteriorate, and DICOPT stops based on its default stopping rule.

Note that if the criterion `stop 1` had been used the search would have been terminated at iteration 3. The reason is that the upper bound to the profit predicted by the MIP (1.42129) exceeds the best current NLP solution (1.9231). Since it can be shown that the MINLP involves convex nonlinear functions, 1.9231 is the global optimum and the criterion `stop 1` is rigorous.

A similar output can be found in the listing file:

```

S O L V E      S U M M A R Y

MODEL process      OBJECTIVE pr
TYPE MINLP         DIRECTION MAXIMIZE
SOLVER DICOPT      FROM LINE 98

**** SOLVER STATUS      1 NORMAL COMPLETION
**** MODEL STATUS      8 INTEGER SOLUTION
**** OBJECTIVE VALUE    1.9231

RESOURCE USAGE, LIMIT      0.771      1000.000

DICOPT Log File

Major Step	Major Iter	Objective Function	CPU time (Sec)	Iterations	Evaluation Errors	Solver
NLP	1	5.35021	0.05	8	0	conopt
MIP	1	2.48869	0.28	7	0	cplex
NLP	2	1.72097<	0.00	3	0	conopt
MIP	2	2.17864	0.22	10	0	cplex
NLP	3	1.92310<	0.00	3	0	conopt
MIP	3	1.42129	0.22	12	0	cplex
NLP	4	1.41100	0.00	8	0	conopt

Total solver times : NLP = 0.05 MIP = 0.72
 Perc. of total : NLP = 6.59 MIP = 93.41

In case the DICOPT run was not successful, or if one of the subproblems could not be solved, the listing file will contain all the status information provided by the solvers of the subproblems. For each iteration the configuration of the binary variables will also be printed. This extra information can also be requested via the GAMS option:

```
option sysout = on ;
```

5.18.10 Special Notes

This section covers some special topics of interest to users of DICOPT.

5.18.10.1 Stopping Rule

Although the default stopping rule behaves quite well in practice there some cases where it terminates too early. In this section we discuss the use of the stopping criteria.

When we run the example `procsol.gms` with stopping criterion 0, we see the following DICOPT log:

```
--- DICOPT: Starting major iteration 10
--- DICOPT: Search terminated: infeasible MIP master problem
--- DICOPT: Log File:
Major Major Objective CPU time Itera- Evaluation Solver
Step Iter Function (Sec) tions Errors
NLP 1 5.35021 0.06 8 0 conopt
```

MIP	1	2.48869	0.16	7	0	cplex
NLP	2	1.72097<	0.00	3	0	conopt
MIP	2	2.17864	0.10	10	0	cplex
NLP	3	1.92310<	0.00	3	0	conopt
MIP	3	1.42129	0.11	12	0	cplex
NLP	4	1.41100	0.00	8	0	conopt
MIP	4	0.00000	0.22	23	0	cplex
NLP	5	0.00000	0.00	3	0	conopt
MIP	5	-0.27778	0.16	22	0	cplex
NLP	6	-0.27778	0.00	3	0	conopt
MIP	6	-1.00000	0.16	21	0	cplex
NLP	7	-1.00000	0.00	3	0	conopt
MIP	7	-1.50000	0.22	16	0	cplex
NLP	8	-1.50000	0.00	3	0	conopt
MIP	8	-2.50000	0.11	16	0	cplex
NLP	9	-2.50000	0.00	3	0	conopt
MIP	9	*Infeas*	0.11	0	0	cplex

```

--- DICOPT: Terminating...
--- DICOPT: Stopped on infeasible MIP

```

```

    The search was stopped because the last MIP problem
    was infeasible. DICOPT will not be able to find
    a better integer solution.

```

```

--- DICOPT: Best integer solution found: 1.923099
--- Restarting execution
--- PROCSEL.GMS(98) 0 Mb
--- Reading solution for model process
*** Status: Normal completion

```

This example shows some behavioral features that are not uncommon for other MINLP models. First, DICOPT often finds the best integer solution in the first few major iterations. Second, in many cases as soon as the NLP's start to give worse integer solution no better integer solution will be found. This observation is the motivation to make stopping option 2, where DICOPT stops as soon as the NLP's start to deteriorate, the default stopping rule. In this example DICOPT would have stopped in major iteration 4 (you can verify this in the previous section). In many cases this will give the best integer solution. For this problem, DICOPT has indeed found the global optimum.

Based on experience with other models, we find that the default stopping rule (stop when the NLP becomes worse) performs well in practice. In many cases it finds the global optimum solution for both convex and non-convex problems. In some cases, however, it may provide a sub-optimal solution. In those cases where you want more reassurance that no good integer solutions are missed you can use one of the other stopping rules.

Changing the MIP or NLP solver can change the path that DICOPT follows, since the sub-problems may have non-unique solutions. The optimum stopping rule for a particular problem depends on the MIP and NLP solvers used.

The bounds of the MIP master problem are not rigorous in the case of non-convex problems. Therefore, the global optimum can be cut-off with `stop 1`. However, this option is the best stopping criterion for convex problems.

5.18.10.2 Solving the NLP Problems

Using a combination of NLP solvers has been found effective in cases where the relaxed NLP and/or the other NLP sub-problems are very difficult. For example, MINOS has many more difficulties to establish if a

model is infeasible, so one would like to use CONOPT for NLP subproblems that are either infeasible or barely feasible. The `nlp solver` option can be used to specify the NLP solver to be used for each iteration.

Infeasible NLP sub-problems can be problematic for DICOPT. Those subproblems cannot be used to form a new linearization. Effectively only the current integer configuration is excluded from further consideration by adding appropriate integer cuts, but otherwise an infeasible NLP sub-problem provides no useful information to be used by the DICOPT algorithm. If your model shows many infeasible NLP sub-problems you can try to use the `infeasder` option. Otherwise a strategy that can help is to introduce explicit slack variables and add them with a penalty to the objective function.

Assume your model is of the form:

$$\begin{aligned} \min \quad & f(x, y) \\ & g(x, y) \sim b \\ & \ell \leq x \leq u \\ & y \in \{0, 1\} \end{aligned}$$

where $\sim$ is a vector of relational operators $\{\leq, =, \geq\}$. x are continuous variables and y are the binary variables. If many of the NLP subproblems are infeasible, we can try the following `elastic` formulation:

$$\begin{aligned} \min \quad & f(x, y) + M \sum_i (s_i^+ + s_i^-) \\ & y = y^B + s^+ - s^- \\ & g(x, y) \sim b \\ & \ell \leq x \leq u \\ & 0 \leq y \leq 1 \\ & 0 \leq s^+, s^- \leq 1 \\ & y^B \in \{0, 1\} \end{aligned}$$

I.e., the variables y are relaxed to be continuous with bounds $[0, 1]$, and binary variables y^B are introduced that are related to the variables y through a set of the slack variables s^+, s^- . The slack variables are added to the objective with a penalty parameter M . The choice of a value for M depends on the size of $f(x, y)$, on the behavior of the model, etc. Typical values are 100 or 1000.

5.18.10.3 Solving the MIP Master Problems

MIP master problems may become expensive to solve when there are many discrete variables. One of the first things to try is to see if a different MIP solver can solve your particular problems more efficiently.

Different formulations can have dramatic impact on the performance of MIP solvers. Therefore it is advised to try out several alternative formulations. The use of priorities can have a big impact on some models. It is possible to specify a nonzero value for `OPTCA` and `OPTCR` in order to prevent the MIP solver from spending an unacceptable long time proving optimality of MIP master problems.

If the MIP master problem is infeasible the DICOPT solver will terminate. In this case you may want to try the same reformulation discussed in the previous paragraph.

5.18.10.4 Feasibility Pump

The feasibility pump is similar to the Outer-approximation, but its objective is to completely focus on finding good feasible solutions rather than optimal ones. The main idea of this algorithm is to decompose the original mathematical programming problem in two parts: integer feasibility and constraint feasibility. By solving an MIP subproblem its solution is an integer feasible solution, which may violate the constraints; and by solving a continuous relaxation of the original MINLP (NLP subproblem) the solution is constraint feasible but might not be integral. By minimizing in successive iterations the distance between these two types of solutions it is expected to achieve a solution that is both constraint and integral feasible.

The feasibility pump can be used as a standalone solver for convex MINLP problems. This is achieved by iteratively applying the method, while including a bound to the objective function. This bound is obtained by the best known solution and an epsilon improvement. This will result in the global optimum of a convex MINLP [47]. The drawback of this algorithm is that it may require many iterations, since each time the objective function is restricted to improve only by epsilon.

In DICOPT, the feasibility pump can be applied before the Outer-approximation method by setting option `feasumpump`. In the feasibility pump, large improvements in the objective function are enforced at each iteration (option `fp.cutoffdecr`). After the method finishes, all the cuts and the best known solution are passed to the Outer-approximation method to prove optimality. More details on the implementation of the feasibility pump in DICOPT can be found in [36].

5.18.10.5 Model Debugging

In this paragraph we discuss a few techniques that can be helpful in debugging your MINLP model.

- Start with solving the model as an RMINLP model. Make sure this model solves reliably before solving it as a proper MINLP model. If you have access to different NLP solvers, make sure the RMINLP model solves smoothly with all NLP solvers. CONOPT, especially, can generate useful diagnostics such as Jacobian elements (i.e. matrix elements) that become too large.
- Try different NLP and MIP solvers on the subproblems. Example: use the GAMS statement `OPTION NLP=KNITRO`; to solve all NLP subproblem using the solver KNITRO.
- The GAMS option statement `OPTION SYSOUT = ON`; can generate extra solver information that can be helpful for diagnosing problems.
- If many of the NLP subproblems are infeasible, add slacks as described in section [Solving the NLP Problems](#).
- Run DICOPT in pedantic mode by using the DICOPT option: `CONTINUE 0`. Make sure all NLP subproblems solve to optimality.
- Don't allow any nonlinear function evaluation errors, i.e. keep the DOMLIM limit at zero. See the discussion on DOMLIM in section [The OPTION Statement](#).
- If you have access to another MINLP solver such as AlphaECP, Bonmin, or SBB or even global solvers like Antigone or BARON, try to use a different solver on your model. To select another solver (here SBB) use the following GAMS option statement: `OPTION MINLP=SBB`;
- Individual NLP or MIP subproblems can be extracted from the MINLP by using the `CONVERT` solver, which will write a model in scalar GAMS notation that can then be solved using any GAMS NLP or MIP solver. E.g., to generate the second NLP subproblem, you can use the following DICOPT option: `NLPSOLVER CONOPT CONVERT`. The model will be written to the file `GAMS.GMS`. A disadvantage of this technique is that some precision is lost due to the fact that files are being written in plain ASCII. The advantage is that you can visually inspect these files and look for possible problems such as poor scaling.

5.19 EXAMINER

5.19.1 Introduction

This document describes GAMS/Examiner, a tool for examining points and making an unbiased, independent assessment of their merit. In short, it checks if solutions are *really* solutions. As an example, it can take a solution point reported as optimal by a solver and examine it for primal feasibility, dual feasibility, and optimality. Examiner has a number of different modes, allowing it to check the input point from GAMS/Base as well as the solution passed by a solver back to GAMS.

Many of the tests done by Examiner (perhaps all of them!) are already being done by the GAMS solvers, so Examiner is in a sense redundant. However, the ability to make an independent, transparent check of a solver's solution is very useful in solver development, testing, and debugging. It is also useful when comparing the solutions returned by two different solvers. Finally, a tool like the Examiner allows one to examine solutions using different optimality tolerances and optimality criteria in a way that is not possible when working with the solvers directly.

GAMS/Examiner is installed automatically with your GAMS system. Without a GAMS/Base license, examiner will run in student or demonstration mode (i.e. it will examine small models only).

5.19.2 Usage

Examiner can be used with all supported model types. Since Examiner doesn't really solve any problems, it is not a good choice for a default solver, and when installing GAMS it does not appear as an option in the list of possible solver defaults. However, you can choose Examiner via the command line:

```
gams trnsport LP=examiner;
```

or via a GAMS option statement

```
option LP=examiner;
```

somewhere before the `solve` statement.

Since Examiner is not really a solver, many of the usual GAMS options controlling solvers have no impact on it. However, the `sysout` option is interpreted in the usual way.

The optimality checks done in Examiner are first-order optimality checks done at a given point. A discussion here of these conditions and all they imply would be redundant: any good intro text in optimization will cover them. For linear programming, first-order optimality is all one needs to prove global optimality. For nonlinear programming, these conditions may or may not be necessary or sufficient for optimality; this depends on the convexity of the feasible set and objective and the form of the constraints. For integer programming models, these checks only make sense if we turn the global problem into a local one by adding bounds to the model, essentially fixing each discrete variable to its current value; these bounds are added automatically by Examiner.

Examiner runs in two basic modes of operation: it can examine the input point passed from GAMS/Base to the solver, and it can examine the point passed from the solver back to GAMS. Each mode can be used independent of the other. By default it will operate in the first mode, examining the initial "solution" passed to it by GAMS, but only if GAMS indicates it is passing an advanced basis to the solver (cf. the GAMS User Guide and the `bratio` option). If you wish to use the second `solver-check` mode, you may specify an appropriate subsolver using the `subsolver` option (see section [Options](#)). If no `subsolver` is selected, the default solver for the model type being solved is used. In most cases you will want to use an option file to specify exactly what type of examination you wish to perform. The rules for using an option file are described in [The Solver Options File](#).

5.19.2.1 Solution Points: Definition

There are a number of different ways a solution point can be defined. Of course the different definitions will typically result in the same points being produced, but there are cases where this will not be precisely so. Since Examiner is intended to explore and analyze these cases, we must make these definitions precise. The following four points are defined and used in Examiner:

1. The **gamspoint** is the input point provided by GAMS to Examiner. The GAMS input point includes level & marginal values for the rows and columns: Examiner uses these exactly as given.
2. The **initpoint** is determined by the variable levels (primal vars) and equation marginals (dual vars) provided by GAMS to Examiner. These values are used to *compute* the equation levels and variable marginals / reduced costs using the function evaluator in Examiner, rather than using the values passed in by GAMS.
3. The **solupoint** is similar to the **initpoint**: it uses the variable levels (primal vars) and equation marginals (dual vars) to *compute* the equation levels and variable marginals. The variable levels and equation marginals used are those returned by the subsolver.
4. The **solvpoint** is the point returned by the subsolver. The subsolver returns both level and marginal values for the rows and columns: Examiner uses these, exactly as given.

5.19.2.2 Checks Performed

There are a number of checks that can be performed on any of the [solution points](#). By default, Examiner tries to choose the appropriate checks. For example, if a primal simplex solver returns a model status of nonoptimal, the only checks that make sense are feasibility in the primal variables and constraints. However, this automatic choice of appropriate checks is not possible when checking points passed in from GAMS/Base.

1. **Primal variable feasibility**: check that all primal variables are within bounds.
2. **Primal constraint feasibility**: check that all primal constraints are satisfied.
3. **Dual variable feasibility**: check that all dual variables are within bounds.
4. **Dual constraint feasibility**: check that all dual constraints are satisfied.
5. **Primal complementary slackness**: check complementarity between the primal variables and the dual constraints / reduced costs.
6. **Dual complementary slackness**: check complementarity between the dual variables / equation marginals and the equation slacks.
7. **Equilibrium condition complementarity**: check complementarity of the equation/variable pairs in complementarity models (MCP, MPEC).

The checks above are implemented with default tolerances. These tolerances can be changed via an option file (see section [Options](#)).

Different ways exist to check the items mentioned above. For example, different norms can be used to measure the error of the residual when checking for primal feasibility. Currently, we have only implemented one way to make these checks.

5.19.2.3 Scaling

By default, Examiner makes its checks on the original, unscaled model. In many cases, however, it is important to take scaling into account. Consider the effect of row scaling on the simple constraint $x^2 \leq 9$ where $x = 3.5$. Multiplying this constraint through by large or small constants changes the amount of the constraint violation proportionately, but the distance to feasibility is not changed. Applying row scaling to the original model eliminates this problem.

Most solvers scale a model before solving it, so any feasibility or optimality checks and tolerances are applied to the scaled model. The process of unscaling the model can result in a loss of feasibility or optimality. Even though we do not have access to the scales applied by the solver and cannot precisely construct the same scaled model, we can get a better idea of how the solver performed by looking at a model scaled by Examiner than by looking at the original.

It is also interesting to see what the model scaling looks like, even if we do not apply the scales to do the Examiner checks. If the row scales are in a nice range, say $[.1, 100]$, we can have some confidence that the model is well-scaled. In contrast, if the row scales are in the range $[1, 1\text{e}8]$ we may question the precision of the solution provided.

For each row, Examiner computes the true row scale as

$$\max(\|RHS_i\|, \max_j(\|A_{ij}\| \cdot \max(1, \|x_j\|)))$$

In this way variables with a large level value lead to large scale factors. To make the scale factor independent of the variable values, use an option file line of "AbsXScale 0". This replaces the term $\max(1, \|x_j\|)$ above with 1.

Since the user may wish to limit the size of the scale factors applied, the true row scales are projected onto the scale factor bounds to get the applied scale factors. The scale factors are applied when making a scaled check by dividing the rows by the scale factors and multiplying the corresponding Lagrange multipliers by these same factors. When making unscaled checks information about the true scales is still included in the output to give the user a hint about potential scaling issues.

Note that the scaled and unscaled checks are made independently. By default only the unscaled checks are performed. If you turn the scaled checks on via an option file line "scaled 1", this will not turn off the unscaled checks. You will need an option file line of "unscaled 0" to turn off unscaled checks.

5.19.3 Options

The following options control the behavior of GAMS/Examiner. Many of these are boolean (i.e. on/off) options. In this case, zero indicates off, nonzero on. For details on how to create and use an option file, see the section on [the Solver Option File](#).

5.19.3.1 General Options

Option	Description	Default
absXScale	Whether to make scale factors dependent on x values. If on, the matrix coefficients are multiplied by $\max(1, \text{abs}(x))$ when computing the scale factors. If off, the matrix coefficients are taken as is. See Section Scaling .	1
dumpGamsPoint	Whether to dump the GamsPoint to a basis file in GAMS source format.	0
dumpInitPoint	Whether to dump the InitPoint to a basis file in GAMS source format.	0

Option	Description	Default
dumpSoluPoint	Whether to dump the SoluPoint to a basis file in GAMS source format.	0
dumpSolvPoint	Whether to dump the SolvPoint to a basis file in GAMS source format.	0
examineGamsPoint	Whether to examine the GamsPoint.	0
examineInitPoint	Whether to examine the InitPoint. By default, this option is on if GAMS/Base passes an advanced basis, and off otherwise.	auto
examineSoluPoint	Whether to examine the SoluPoint. By default, this option is on if a subsolver has been selected, and off otherwise.	auto
examineSolvPoint	Whether to examine the SolvPoint. By default, this option is on if a subsolver has been selected, and off otherwise.	auto
fCheckAll	If set, forces all checks on or off.	auto
fCheckATTR	If set, forces the model attributes check on or off.	auto
fCheckDCMP	If set, forces the dual complementary slackness check on or off.	auto
fCheckDCON	If set, forces the dual constraint feasibility check on or off.	auto
fCheckDVAR	If set, forces the dual variable feasibility check on or off.	auto
fCheckPCMP	If set, forces the primal complementary slackness check on or off.	auto
fCheckPCON	If set, forces the primal constraint feasibility check on or off.	auto
fCheckPVAR	If set, forces the primal variable feasibility check on or off.	auto
perpSys	Controls output during examination of solution points. If on, print out the point in a way that allows for easy visual inspection and verification of the KKT or first order optimality conditions. First, the primal level values and bounds are printed next to the reduced costs. Next, the duals levels and bounds are printed next to the row slacks.	0
returnGamsPoint	Whether to return the GamsPoint as a solution to GAMS/Base.	0
returnInitPoint	Whether to return the InitPoint as a solution to GAMS/Base.	auto
returnSoluPoint	Whether to return the SoluPoint as a solution to GAMS/Base.	auto
returnSolvPoint	Whether to return the SolvPoint as a solution to GAMS/Base.	auto
scaled	Whether to apply checks to a scaled version of the model.	0
scaleLB	Lower bound for applied row scales.	1
scaleUB	Upper bound for applied row scales.	maxdouble
showSlacks	explicitly show the infeasibilities or slacks for failed checks	0
subSolver	Indicates what subsolver to run. By default, the subsolver used is the default subsolver for the model type in question.	auto
subSolverOpt	optfile value to pass to the subsolver	auto
trace	If set, trace information will be computed and appended to this file.	none
unScaled	Whether to apply checks to the original, unscaled version of the model.	1

5.19.3.2 Tolerance Options

Option	Description	Default
dualCSTol	Tolerance on dual complementary slackness, i.e. between the dual variables and the primal constraints.	1e-7
dualFeasTol	Tolerance on dual feasibility, i.e. to check feasibility of the dual variables and the dual constraints.	1e-6
ECTol	Tolerance on equilibrium condition complementarity. Applicable to MCP and MPEC models, where the equilibrium conditions are given by the equation-variable pairs in the model statement.	1e-6
primalCSTol	Tolerance on primal complementary slackness, i.e. between the primal variables and the dual constraints.	1e-7
primalFeasTol	Tolerance on primal feasibility, i.e. to check feasibility of the primal variables and constraints.	1e-6
showTol	relative tolerance for showSlacks - we only want to see explicit slacks that are relatively small	1e-4

5.20 GAMSCHK

Abridged GAMSCHK USER DOCUMENTATION - Version 1.1

A System for Examining the Structure and Solution Properties of Linear Programming Problems Solved using GAMS

Bruce A. McCarl, Professor, Department of Agricultural Economics, Texas A&M University

April 2013 :

5.20.1 GAMSCHK USER DOCUMENTATION

This document describes procedures designed to aid users who wish to examine empirical GAMS models for possible flaws. The conceptual basis for many of the routines herein is supplied in McCarl and Spreen, and McCarl et.al.

The function of the specific components of GAMSCHK are to:

- List coefficients for user selected equations and/or variables using the DISPLAYCR procedure.
- List the characteristics of selected groups of variables and/or equations using MATCHIT.
- List the characteristics of equation and variable blocks using BLOCKLIST.
- Examine a GAMS model to see whether any variables and equations contain specification errors using ANALYSIS.
- Generate schematics depicting the characteristics of coefficients by variable and equation blocks using BLOCKPIC.
- Generate a schematic for small GAMS models or portions of larger models depicting the location of coefficients by sign and magnitude using PICTURE.
- Reconstruct the reduced cost of variables and the activity within equations after a model solution using POSTOPT.
- Help resolving problems with unbounded or infeasible models using NONOPT and ADVISORY.

5.20.2 General Notes on Package Usage

GAMSCHK must replace a solver. This is done using a GAMS option statement of the form:

```
OPTION LP= GAMSCHK;
```

or

```
OPTION NLP=GAMSCHK;
```

or

```
OPTION MIP=GAMSCHK;
```

which replaces either the solver of the particular model type with GAMSCHK. In turn, the user will invoke the solver using the statement:

```
SOLVE MODELNAME USING LP MINIMIZING OBJNAME;
```

where MODELNAME is the name used in the GAMS MODEL statement; OBJNAME is the objective variable name for the model; and the type of solver that GAMSCHK has replaced which must also be able to solve this type of problem (LP, NLP, MIP, ...) is identified. The following are examples of GAMS sequences which can be added to the GAMS file:

```
OPTION NLP=GAMSCHK;  
SOLVE TRANSPORT USING NLP MINIMIZING Z;
```

or

```
OPTION LP=GAMSCHK;  
SOLVE FEED USING LP MINIMIZING COST;
```

or

```
OPTION MIP=GAMSCHK;  
SOLVE RESOURCE USING MIP MAXIMIZING PROFIT;
```

5.20.2.1 Selecting a Procedure and Providing Input - the *.GCK File

GAMSCHK requires that the user indicate which procedures are to be employed. This is specified through the use of the *.GCK file where the * refers to the filename from the GAMS execution instruction.² The general form of that file is:

```
FIRST PROCEDURE NAME
  ITEM SELECTION INPUT

SECOND PROCEDURE NAME
  ITEM SELECTION INPUT
```

Spaces and capitalization are ignored in this input. For example, a *.GCK file could look like

```
DISPLAYCR
    variables
        SELL(*,*,FANCY)
    maketable
Invariables
    transport(plant2,*,fancy)
Equations
    objT
    notthere
inequations
    resourceq(plant1)
PICTURE
```

The first procedure name in this case is DISPLAYCR and the following 10 lines indicate the items to be selected. Then, we also request PICTURE. Selection entries are treated using several assumptions. In particular:

1. If the *.GCK file is empty then it is assumed that the BLOCKPIC procedure is selected.
2. Spaces may be freely used in the GCK input file.
3. Upper, lower, or mixed case input is accepted.
4. GAMSCHK recognizes certain words. These words are listed in [Appendix A: Reserved Names](#) and cannot be used as variable or equation names.

5.20.2.2 The *.GCK file: General Notes on Item Selection

Some of the procedures permit selection of variables, equations or functions. Specifically, the DISPLAYCR, PICTURE, POSTOPT, and MATCHIT procedures accept input identifying the variables and equations to be utilized. Also NONOPT accepts limited input controlling its function. General observations about the selection requests are

1. Variables can be chosen by entering the word VARIABLE or VARIABLES possibly with a modifier, followed by variable selection statements.

²Thus, if the GAMS instructions are in the file called MYMODEL, and GAMS is invoked using the DOS command GAMS MYMODEL, then the GCK file would be called MYMODEL.GCK. If GAMS instructions are on the filename with a period in it then the name up to the period will be used, i.e., the GCK file associated with MYMODEL.IT would be MYMODEL.GCK

2. Variables can also be selected using the `INEQUATION` or `INEQUATIONS` syntax followed by names of equations. Use of this syntax results in selection of variables with coefficients in the named equations.
3. Equations are selected by entering the keyword, `EQUATION` or `EQUATIONS` possibly with a modifier, followed by equation selection statements.
4. Equations can also be selected using the `INVARIABLE` or `INVARIABLES` syntax followed by names of variables. Use of this syntax results in selection of equations in which the named variables have coefficients.
5. Certain item selection modifier keywords can be used depending on procedure. The `INTERSECT` keyword works with procedures `DISPLAYCR` and `POSTOPT`. The `INEQUATION` and `INVARIABLE` keywords work with procedures `DISPLAYCR`, `PICTURE` and `POSTOPT`. `LISTEQUATION` and `LISTVARIABLE` keywords work with the `MATCHIT` procedure. `INSOLUTION`, `NOTINSOLUTION`, `BINDING`, and `NOTBINDING` keywords work with `POSTOPT`. The keywords `VERBOSE` and `IDENTIFY` work with `NONOPT`.
6. If variable or equation names do not follow the keyword, then usually all variables or equations are assumed selected.

When variables or equations are to be selected after an item selection keyword, a number of input conventions apply. These conventions are:

1. If a variable or equation name is entered without any following parentheses, then all cases for that variable or equation are selected.
2. The selection entries identify specific elements from among the sets over which the variables and equations are defined. In specifying these elements one can use various wild card entries as discussed below or an element name. Note GAMS set or subset names cannot be used. Set membership information is not available to the GAMSCHK routines.
3. Wild cards can be used to select items. An `"*"` will select any item. For example, `"B*"` will select anything starting with a B. `"A?B"` will select anything beginning with A, ending with B with one intervening alpha numeric character.
4. When individual elements are specified, you need not enclose them in quotes (`"`).
5. Quotes must be specified to include set item names with spaces, and special characters. In that case wild cards do not work and all input up to the next quote is simply copied.
6. When the selected item has more dimensions than specified, then all later dimensions are handled as if a wild card were specified. For example, when a variable X is defined with reference to 4 sets in the GAMS instructions, but only 3 parameters are specified in the GAMSCHK input, then the request is handled as if all elements of the 4th are desired.
7. When the selected item has less dimensions in GAMS than in the item selection input, then all additional dimensions are ignored. Thus, when a variable X is defined with reference to 3 sets in GAMS, but 4 parameters are specified in the item selection file, then the 4th specification is ignored.
8. Multiple selection statements can appear on successive lines of the `*.GCK` file. Output is ordered according to the way items are found in the GAMS file which is determined by the ordering of variables, equations, and set elements in the original GAMS input.
9. Error messages will be generated when an entry cannot be matched to a GAMS element.
10. Examples include

Example	Explanation
X(*,CLEVELAND)	which indicates that X will be selected for any element of the first set where the element in the second set equals CLEVELAND
X(SEATTLE)	when X is two dimensional selects all cases where the first set element is SEATTLE
X(SEATTLE,CHICAGO,Z)	when X is two dimensional selects the case where the first set element equals SEATTLE, and the second element equals CHICAGO. The third is ignored.
X	all X's will be selected
X(S*, C.O, Z)	when X is three dimensional selects where all X's with first element starting with S, second element beginning with C and ending with O and third element Z will be selected.
*	all variables or equations will be selected
{empty selection set}	all variables or equations will be selected

5.20.2.3 Procedure Output

In all cases the output generated by the procedure will be written to the *.LST file associated with the GAMS call. Thus, if the file is called MODEL with the *.GCK file (MODEL.GCK), then all output will be on MODEL.LST.

5.20.2.4 Nonlinear Terms

GAMS models examined with GAMSCHK may involve nonlinear terms. In such cases, GAMSCHK uses the value of the nonlinear term sent forth from GAMS which is an accurate marginal, not total value. GAMS develops this value based on the current level value of the variable. This will either be: a) the starting point selected by GAMS, if the model has not been solved, or b) the current solution value, if the model has been solved. The most accurate portrayals of the coefficients will be generated after the model has been solved through a GAMS SOLVE command before invoking GAMSCHK. Some cases may require a solution and/or the specification of a good starting point before using GAMSCHK. Also, nonlinear terms potentially cause misleading coefficients as those values are local marginal, not global, values determined by the current levels of the variables. Nonlinear terms are marked with *** in the DISPLAYCR, POSTOPT, and NONOPT output.

5.20.2.5 Entering Comments in the *.GCK File

The *.GCK file has been programmed so that users can enter comments. These comments can take one of two forms. Comments that begin with a hash mark are copied to the output when the program runs. Comments which begin with a question mark are simply overlooked. Thus, one can temporarily comment GAMSCHK selection statements making them inactive by putting in question marks. If multiple procedures are being run or if some sort of output is decided to screen in the computer output then the hash marks can be entered.

5.20.2.6 Controlling Page Width in the *.GCK File

When running multiple procedures, in particular the pictures with other procedures, it is often desirable to have some procedures run with wide page widths, but the rest with a narrower page width. The GCK file provides the option to narrow the page width using a PW= command. In particular, what one can do is run GAMS with a large page width, i.e. run GAMS BLOCK pw=200, then insert in the GCK file instructions which narrow that page width for selected procedures. Users should note that the page width can never be made any wider than the default page width when running with GAMS. Information in excess of the page width will be ignored. Thus, if the model is run under the default status which has a page width of 75 characters then GAMSCHK will reduce the page width down to the maximum page width allowed. Consequently, the pw= command can only be used to narrow the page width from the default page width, not increase it.

5.20.2.7 Running Multiple Procedures

GAMSCHK can run multiple procedures during one job. This is done by simply stacking the sequence of the commands in the .GCK file.

5.20.3 Use of the Procedures

The following section describes the procedures available in GAMSCHK and their input requirements.

5.20.3.1 DISPLAYCR

Brief Purpose: DISPLAYCR displays all coefficients from the empirical model for a set of user selected equations and variables. All nonzero coefficients under each selected variable or in each selected equation are displayed with the associated variable or equation name and coefficient value. The selection entries may refer to all terms in equations under variables or only those coefficients at the intersection of the selected variables and equations.

Usage Notes: This option mirrors the GAMS LIMCOL and LIMROW options, but allows the user to select the specific items to be displayed. Partial displays within a variable or equation are also allowed using INTERSECT. Use of VARIABLE and EQUATION keywords followed by selection statements allows one to select variables and equations. Use of the INVARIABLE command allows users to select the equations which are associated with a particular variable. For example, if one is having trouble with a particular variable and wants to look at competition in the equations in which it appears, then selecting the variable under the INVARIABLE command will display the complete contents of all the equations in which the selected variables have coefficients. Similarly, the INEQUATION command will display the complete contents of all variables which fall in a particular equation. Nonlinear terms are marked with ***. When the keyword INTERSECT is found then only the coefficients at the intersection of the specified equations and variables are selected. Use of INTERSECT with the INVARIABLE syntax results in the named variables and the equations in which they fall being selected. Similarly, use of INTERSECT with the INEQUATION syntax results in selection of the named equations and the variables which fall in those equations

Note that when GAMS internal scaling features are employed the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: The keyword DISPLAYCR is entered followed by optional lines of item selection input identifying the variables and equations to be displayed. This file can contain the keywords VARIABLE, INVARIABLE, EQUATION, and INEQUATION, with each followed by a specification of the items to be selected using the procedure input specification conventions that were described above. The keyword INTERSECT can also be used. Several special cases are relevant:

- If none of the above keywords are found after DISPLAYCR and another procedure name does not follow, then the input is assumed to identify variables.
 - If input is found but the VARIABLE or INEQUATION keyword cannot be found then no variables are assumed selected.
 - If the VARIABLE keyword is entered, but is followed by the end of file or an Appendix A reserved word and INEQUATION does not appear, then all variables are assumed selected.
 - If the EQUATION or INVARIABLE keyword cannot be found, then no equations are assumed selected.
 - If the EQUATION keyword is entered, but is followed by the end of the file or a reserved word and the INVARIABLE command does not occur, then all equations are assumed selected.
-

- The keyword `INVARIABLE` is allowed. It should be followed by variable selection statements. In turn, `DISPLAYCR` selects all equations which have nonzero entries under the `INVARIABLE` selections.
- The keyword `INEQUATION` may be used. It should be followed by equation selection statements. In turn, `DISPLAYCR` selects all variables which have nonzero entries in the `INEQUATION` selections.
- The keyword `INTERSECT` causes only coefficients at the intersection of the specified equations and variables to be displayed. This occurs for all specifications in this run of `DISPLAYCR`. One should use `DISPLAYCR` again if some intersecting and some non-intersecting displays are desired.
- When `INTERSECT` appears along with `INVARIABLE`, the named variable is selected along with all the equations in which it falls. Similarly, when `INTERSECT` and `INEQUATION` appear then all the named equations and the variables appearing in them are selected.

5.20.3.2 MATCHIT

Brief Purpose: `MATCHIT` retrieves the names and characteristics of selected variables and equations. The characteristics reported tell whether the items are nonlinear as well as reporting scaling characteristics and counts of the coefficients. `MATCHIT` will summarize the items which match a request or list all the items individually.

Usage Notes: The input to `MATCHIT` can include the keywords `VARIABLE` and `EQUATION` along with those keywords with the prefix `LIST` attached. When the `LIST` prefix is not used, the procedure summarizes the characteristics of all items which match the item requests counting the number of matching items, the number of those items which are nonlinear, the total coefficients under or in those items, the number of positive, negative, and nonlinear coefficients that fall under or in those items. This does not list the names of the individual items which match. If the `LIST` prefix is used (entering `LISTVARIABLE` or `LISTEQUATION`) then the individual matching items are printed in the order in which they are encountered. For each matching item the information tells whether it is nonlinear, how many total coefficients it has, the count of positive, negative, and nonlinear coefficients falling under it, and the minimum and maximum absolute values of coefficients under it (excluding the objective function coefficient).

Note that when GAMS internal scaling features are employed then by default scaled output is displayed. This can be altered using the `DESCALE` feature of the solver options file.

Input File: This file contains the keyword `MATCHIT`, followed by optional item selection input data. The optional input identifies the variables and equations to be displayed. This input can contain the keywords `VARIABLE` or `LISTVARIABLE` followed by a specification of the variables to be selected using the procedure input specification conventions that were described above. This can be followed by the keyword `EQUATION` or `LISTEQUATION` and the specified entries.

Several special cases are relevant:

- If the procedure name is not followed by any selection input, then a count of all variables and equations appears.
- If the input is found, but the input does not begin with `VARIABLE`, `EQUATION`, `LISTVARIABLE`, or `LISTEQUATION` keywords, then the input is assumed to contain variable names.
- If the `VARIABLE` keyword is entered, but is not followed by variable selection statements, and `LISTVARIABLE` does not appear, then all variables are assumed selected.
- If the `EQUATION` or `LISTEQUATION` keyword cannot be found, then equations are assumed selected.

- If the EQUATION keyword is entered, but is not followed by equation selection statements or a LISTEQUATION entry, then all equations are assumed selected.
- The keyword LISTVARIABLE is allowed. It should be followed by variable selection statements. In turn, MATCHIT lists all variables which fall under the request.
- The keyword LISTEQUATION may also be used. It should be followed by equation selection statements. In turn, MATCHIT lists all equations which fall under the request.

5.20.3.3 ANALYSIS

Brief Purpose: Analyzes the structure of all variables and equations. Information is given on errors involving obvious model misspecifications causing redundancy, zero variable values, infeasibility, unbound-ness, or obvious constraint relaxations in linear programs. The checks are those identified in [Tables 1, 2](#) and [3](#).

Usage Notes: The analysis tests given in [Tables 1](#) and [2](#) are utilized to determine if individual variables or equations in the model possess obvious specification errors. One test, for example, considers whether or not in a maximization problem a variable appears which has a positive return in the objective function, but no coefficients in the constraints indicating an obviously unbounded model. Similarly, information is provided on whether certain equations can never be satisfied. For example, tests examine whether an equality equation appears with a negative right hand side and all positives on the left hand side. Also tests see whether the bounds on variables preclude equation satisfaction or make equations redundant ([Table 3](#)). In ANALYSIS these tests are applied to each and every variable and equation. The BLOCKPIC and BLOCKLIST routines utilize the tests on a block by block basis. Thus, the messages will be triggered only if every variable or equation in that block has the same problem. Also interactions between variables and equations are not checked so ANALYSIS only finds flaws contained in individual variables/equations.

Input File: The keyword ANALYSIS is all that is accepted.

5.20.3.4 BLOCKLIST

Brief Purpose: The BLOCKLIST procedure displays the number and characteristics of the items in each GAMS variable and equation block.

Usage Notes: The characteristic information gives:

1. The variable sign restriction or equation inequality type.
2. The number of variables or equations in this block;
3. The number of variables or equations with at least one nonlinear term in this block.
4. The number of positive coefficients under the variables or in the equations.
5. The number of negative coefficients under the variables or in the equations.
6. The number of nonlinear coefficients under the variables or in the equations.
7. The largest coefficient in absolute value in this block;
8. The smallest coefficient in absolute value in this block. Analysis tests are also performed as discussed under the ANALYSIS procedure.

Note that when GAMS internal scaling features are employed, the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: No input other than the procedure name is needed.

5.20.3.5 BLOCKPIC

Brief Purpose: Generates model schematics and scaling information. The schematics depict coefficient signs, total and average number of coefficients within each GAMS equation and variable block.

Usage Notes: These schematics are designed to aid users in identifying flaws in coefficient placement and sign. The summary information on problem scaling characteristics is designed to help users in scaling data. The scaling information is usually reported after any GAMS scaling (using the `variablename.scale` and `equationname.scale` features) but before solver scaling. (The user can change whether descaling is done - see the options file). Analysis tests are done using the procedures in [Tables 1](#) and [2](#).

Note that when GAMS internal scaling features are employed the default option is that the scaled output is displayed. This can be altered using the `DESCALE` feature of the solver options file.

Input File: The keyword `BLOCKPIC` is all that is recognized.

5.20.3.6 PICTURE

Brief Purpose: Generates a schematic depicting the location, sign and magnitude of coefficients for selected variables and equations. Users can use this schematic to help identify flaws in coefficient placement, magnitude, or sign. Reports are also generated on the number of individual elements in the pictured portions of each variable and equation.

Usage Notes: This output can be quite large, so `PICTURE` should only be used for small models or model components. Note that when GAMS internal scaling features are employed, the default option is that the scaled output is displayed. This can be altered using the `DESCALE` feature of the solver options file.

Input File: Optional input instructions may appear after the `PICTURE` keyword. This input selects the variables and equations to be included. Only coefficients at the intersection of the selected variables and equations are portrayed. The selected item in the `.GCK` file can contain the keywords `VARIABLE`, or `INVARIABLE` followed by a specification of the selected variables using the procedure input specification conventions above. This can be followed by the keywords `EQUATION` or `INEQUATION` and the specified entries. Several special cases are also relevant:

- If the `VARIABLE` or `INEQUATION` keywords cannot be found, then all variables are assumed selected.
 - If the `EQUATION` or `INVARIABLE` keywords cannot be found, then all equations are assumed to selected.
 - If the none of the `VARIABLE`, `INVARIABLE`, `EQUATION`, or `INEQUATION` keywords are found, everything is pictured and all other input is ignored.
 - When the `INVARIABLE` keyword is used, then all equations in which those variables have coefficients are selected along with the named variables.
 - When the `INEQUATION` keyword is used, then all variables which have coefficients in the named equations are selected along with the named equations.
-

5.20.3.7 POSTOPT

Brief Purpose: Does post optimality computations. In that capacity POSTOPT either:

- Reconstructs the reduced cost of variables after a GAMS model solution. Modelers can use this information to discover why certain variables are nonbasic or why certain shadow prices take on particular values, or
- Reconstructs the usage and supply across an equation after a GAMS model solution. Modelers can use this information to discover why certain variables or slacks take on particular values, as well as to find out where items within equations are produced and/or used.

Usage Notes: POSTOPT uses essentially the same input conventions as does DISPLAYCR. Thus, the usage notes in that selection are also relevant here. In addition:

1. POSTOPT requires a solution has been obtained GAMSCHK will automatically cause a solver to be invoked unless suppressed by the options file;
2. Nonlinear terms may not be accurate in the row sums as their marginal value not their total value is used but GAMS will have adjusted the right-hand sides for their presence; and
3. Attention can be restricted to only certain types of variables or equations. Variables that are INSOLUTION (Nonzero or with Zero marginals), NOTINSOLUTION (zero with a nonzero marginal) can be requested, BINDING or NONBINDING equations can be focused on.

Note that when GAMS internal scaling features are employed, the default option is that the unscaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: An optional input file is read in, indicating the specific variables desired using the conventions explained under DISPLAYCR above. In addition:

- One can enter INSOLUTION to restrict attention to variables which are nonzero or have zero marginals.
- One can enter NOTINSOLUTION to restrict attention to zero variables.
- The above entries restrict alteration in all VARIABLE or INEQUATION selection statements in a POSTOPT run.
- One can enter BINDING to only consider equations with zero slack. Similarly, NONBINDING considers equations with nonzero slack.
- The above equation specifications restrict all sections by all EQUATION or INVARIABLES items in a POSTOPT run.

5.20.3.8 ADVISORY

Brief Purpose: To identify variables which could be unbounded or equations and variable bounds which could cause a model to be infeasible.

Usage Notes: The ADVISORY procedure causes a presolution report on the set of all: a) variables which could be unbounded and/or b) equations and variable bounds which could cause infeasibility. The tests used are summarized in [Table 3](#). This procedure identifies all variables which would need to be bounded as well as all constraints which need artificial variables if one wishes to diagnose problems in a model. The same output is also generated by NONOPT but the ADVISORY version does not require a solution.

Input file: Just the word ADVISORY

5.20.3.9 NONOPT

Brief Purpose: To help diagnose unbounded and infeasible models.

Usage Notes: The NONOPT procedure can be used in either an informative mode or with models which terminate as unbounded or infeasible. NONOPT will look through an optimal model reporting all variables which may be potentially unbounded or infeasible and all equations which may be infeasible using the checks explained under the ADVISORY section. Also in an unbounded model NONOPT can report the names of unbounded or infeasible variables or equations as well as either budgeting or row summing them. NONOPT runs after a solution and causes a solve to occur.

Input File: NONOPT may be followed by optional keywords IDENTIFY or VERBOSE. The IDENTIFY keyword causes GAMSCHK to report potential unbounded variables and/or infeasible equations. VERBOSE causes full budgets and row summing as done by the POSTOPT procedure on infeasible equations, and/or variables as well as unbounded variables and/or equations. Only the last encountered of the VERBOSE or IDENTIFY keywords will be obeyed. The details on these options are as follows:

1. If the IDENTIFY keyword is used, then the rules in [Table 3](#) are applied to the model. Identify also anticipates that large upper bounds and/or artificial variables may be present. In an optimal condition all variable and equation levels that have exponents greater than the user supplied level filter in the options file (or 6 by default) are identified as items which could be involved with an unbounded model. Similarly, all variables or equations with marginals greater in exponent than the user supplied marginal exponent filter will be identified as items potentially involved with an infeasible model.
2. When the VERBOSE keyword is read then all variables and equations which are listed as nonoptimal or infeasible are treated using the budgeting and row summing aspects of POSTOPT.
3. When no keyword is found and the model solution is not optimal then the nonoptimal equations, infeasible equations and/or nonoptimal variables automatically listed.

5.20.4 Options File

GAMSCHK accepts an option file controlling solver choice (when needed); descaling; and size of the nonoptimal filters; the number of variable and column blocks selection entries allowed. The file is called GAMSCHK.OPT

5.20.4.1 Solver Choice Options

GAMSCHK calls for the solution of the problem when the POSTOPT or NONOPT procedures are used. In doing this, GAMSCHK internally selects the default GAMS solver for a problem class. Users may override this choice using the solver options file. Users may also force or suppress the solution process.

There are 16 solver related keywords allowed in the options file. These are as follows:

OPTION	Purpose
LP	Gives name of solver for LP problems
MIP	Gives name of solver for MIP problems
RMIP	Gives name of solver for RMIP problems
NLP	Gives name of solver for NLP problems
MCP	Gives name of solver for MCP problems
MPEC	Gives name of solver for MPEC problems

OPTION	Purpose
RMPEC	Gives name of solver for RMPEC problems
CNS	Gives name of solver for CNS problems
DNLP	Gives name of solver for DNLP problems
MINLP	Gives name of solver for MINLP problems
RMINLP	Gives name of solver for RMINLP problems
SOLVERNAME	Gives name of solver to be used regardless of problem type
NOSOLVE	Suppresses solution of the problem
SOLVE	Forces solution of the problem
DESCALE	Controls treatment of scaling
OPTFILE	Solver options file number

In the first five cases, the option name is followed by the name of one of the licensed solvers. If the options file is empty, then the default solver will be used. If a solver name is given, then that solver will be used provided it matches the name of a solver GAMS recognizes.

5.20.4.2 When Should I Use SOLVE or NOSOLVE

Ordinarily GAMSCHK will cause a solver to be used if either the POSTOPT or the NONOPT options are used. However, users can force solutions under other cases or suppress solutions if desired.

One should only force a solution (using the SOLVE option) when one wishes to use the solution information after GAMSCHK is done either to examine the solution output or do post optimality calculations. Forcing a solution will not cause GAMSCHK to have improved representations of nonlinear terms. That will only occur when a SOLVE statement is executed before the SOLVE statement involving GAMSCHK.

5.20.4.3 Control of Number of Variable and Row Selections Allowed

The GAMSCHK program uses an upper estimate on the number of variable or equation blocks. In rare circumstances users may wish to override this choice. The options for this are:

OPTION	Purpose
VARBLOCK	Maximum number of variable blocks allowed
EQUBLOCK	Maximum number of equation blocks allowed

These options are followed by a number, but should not be routinely used.

5.20.4.4 Scaling

GAMS users may be utilizing internal features which involve scaling through the ModelName.SCALEOPT=1, VariableName.SCALE, and EquationName.SCALE options. GAMSCHK can work with these options to create output which reflects scaled, unscaled or partially unscaled output. In particular, the command DESCALE can be entered with one of three options: NEVER, ALL, or PART. If you enter NEVER, then none of the model output will be descaled. If you enter ALL, then all of the model output will be descaled. The third option is to use PART. In that case the NONOPT and POSTOPT output will be descaled whereas scaled information will be displayed for PICTURE, BLOCKPIC, BLOCKLIST, MATCHIT and DISPLAYCR. The PART option allows investigation of scaling. If you do not enter a DESCALE option then all information will be reported as if the PART option was chosen.

5.20.4.5 NONOPT Filters

The NONOPT model in "IDENTIFY" mode checks through a model solution to identify large marginals and/or large variable values. The limits on these checks are provided by two options:

OPTION	Purpose
LEVELFILT	Numerical value of exponent on "unbounded levels"
MARGFILT	Numerical value of exponent on "infeasible marginals"

These options provide upper bounds on the exponents of the absolute values for the levels and marginals. They are followed by an integer which gives the exponent. Thus, entries like

```
LEVELFILT 7
MARGFILT 7
```

will cause the reporting of all marginals and levels which are greater in absolute value than 10^7 .

5.20.4.6 Example Options File

The GAMSCHK option file is called GAMSCHK.OPT. An example of a file could look like the following 6 lines:

```
LP          BDMLP
MIP         CBC
VARBLOCK    50
SOLVE
DESCALE     PART
LEVELFILT   4
```

5.20.4.7 Solver Options File

One other important aspect regarding the options file involves the use of a problem solver options file when a solver such as BDMLP, CBC, IPOPT etc. is also being used. As seen above the GAMSCHK.OPT does not recognize option commands such as those which would be submitted to the programming model solvers - BDMLP for example. In all cases GAMSCHK will cause the default option file for the solver to be used when invoking the solver. Thus if BDMLP and the options file is invoked is being used, BDMLP options are controlled by the option file BDMLP.OPT while GAMSCHK.OPT controls GAMSCHK operation. Users can change the number of the solver options file being used by using the OPTFILE parameter in the options file. OPTFILE 2 would cause use of solver options file .OP2.

5.20.5 Known Bugs

There are a few bugs that can cause GAMSCHK to report improper outputs or results. A list of the known bugs, their symptoms and a remedy is given below.

Symptom	Cause	Remedy
Zero Shadow Prices in POSTOPT	Old GAMS version or no Prior Solve	1) Make sure the model was solved, 2) if it was, do not suppress solve in option file, or 3) update to most recent GAMS version
Descaling Does Not Work	Old Version of GAMS	Update
GAMS Blows up after GAMSCHK Runs	Old GAMS version	Ignore, *.LST file, results are fine, can be fixed by updating to the most recent version of GAMS
POSTOPT has error in budgets equal to twice objective function coefficient for nonlinear maximizations	Old GAMS MINOS version	Switch to a minimization formulation or update GAMS/MINOS
ROWSUM does not fully account for the value of nonlinear terms in POSTOPT	Value of nonlinear terms sent from GAMS are only a marginal value	None planned. GAMSCHK would need reprogramming
Error message about size of VARBLOCK or EQNBLOCK	exceeded maximum number of blocks	Modify option file, enlarging or eliminating parameters
GAMSCHK won't run	Files are not properly installed	Recheck installation. If still doesn't work report to author
Zero shadow prices when using NOSOLVE	Old version of GAMS solvers or Shadow prices suppressed	Try changing GAMSCOMP.TXT lines 2 or 0 to 12 or 10, if that doesn't work update GAMS.

5.20.6 Tables

Table 1: Conditions under which a modeler should be advised of potential difficulty for equations without nonlinear terms.

- a/ The PS cases indicate, because the variables in this equation follow this pattern, that:
 1. The variables appearing with nonzeros in this equation are forced to equal zero.
 2. This equation can never be satisfied and is obviously infeasible.
 3. This equation is redundant. The nonnegativity conditions are a stronger restriction.
- b/ In the examples x denotes indexed non-negative variables, y indexed non-positive variables, and z a single unrestricted variable.
- c/ Here and in the cases below at least one nonzero must occur.
- d/ These entries give examples of the problem covered by each warning. Namely, in the first case examining only the nonnegative variables suppose all those variables have signs ≥ 0 but the right-hand-side is zero. Thus, we have $X \geq 0$ and $X \leq 0$ which implies $X = 0$. A warning is generated in that case.
- e/ Only one coefficient is allowed.

Type of constraint	Count of coefficients under a variable of this type with a particular sign						Sign of RHS	Type of PS ^{a/}	Examples ^{b/}
	Nonnegative		Nonpositive		Unrestricted				
	+	-	+	-	+	-			
≤	≥ 0 ^{c/}	0	0	≥ 0	0	0	0	Zero Variables - Case 1	$\sum x \leq 0^{d/}, -\sum y \leq 0,$
	≥ 0	0	0	≥ 0	0	0	-	Infeasible -Case 2	$\sum x \leq -k, -\sum y \leq -k,$
	0	≥ 0	≥ 0	0	0	0	+ or 0	Redundant -Case 3	$-\sum x \leq +k, \sum y \leq +k,$
=	≥0	0	0	≥0	0	0	0	Zero Variables - Case 1	$\sum x = 0, -\sum y = 0, \sum$
	0	≥0	≥0	0	0	0	0	Zero Variables - Case 1	$-\sum x = 0, \sum y = 0, -\sum$
	≥0	0	0	≥0	0	0	-	Infeasible - Case 2	$\sum x - \sum y =$
	0	≥0	≥0	0	0	0	+	Infeasible - Case 2	$-\sum x + \sum y =$
	0	0	0	0	≥0 ^{e/}	≥0 ^{e/}	0	Zero Variable - Case 1	$z = 0, -z =$
≥	0	≥0	≥0	0	0	0	0	Zero Variables - Case 1	$-\sum x \geq 0, \sum y \geq 0, -\sum$
	0	≥0	≥0	0	0	0	0 or +	Infeasible -Case 2	$-\sum x \geq k, \sum y \geq k, -\sum$
	≥0	0	0	≥0	0	0	- or 0	Redundant -Case 3	$\sum x \geq -k, -\sum y \geq -k,$

Table 2: Conditions under which a modeler should be warned about variables in a maximization problem.

Type of Variable	Objective function coefficient sign	Number of a_{ij} 's of a sign in						PS ^{a/}	Example
		$\geq$ rows		$=$ rows		$\leq$ rows			
		+	-	+	-	+	-		
Nonnegative	+	≥ 0	0	0	0	0	≥ 0	Unbounded Variable case 1	$\max x^{b/}$ $x + DQ \geq$ $-x + EQ \leq$
	-	0	≥ 0	0	0	≥ 0	0	Zero optimal solution case 2	$\max -x^{b/}$ $-x + DQ \geq$ $x + EQ \leq$
	0	≥ 0	0	0	0	0	≥ 0	Variable Relaxes constraint case 3	$\max ox^{b/}$ $x + DQ \geq$ $-x + DQ \leq$
	0	≥ 0	0	$\geq 0^{c/}$	$\geq 0^{c/}$	0	≥ 0	Variable Relaxes constraint case 4	$\max ox^{b/}$ $x + DQ \geq$ $x + FQ =$ $-x + EQ \leq$
Nonpositive	-	0	≥ 0	0	0	≥ 0	0	Unbounded Variable case 1	$\max -y^{b/}$ $-y + DQ \geq$ $y + EQ \leq$
	+	≥ 0	0	0	0	0	≥ 0	Zero optimal solution case 2	$\max y^{b/}$ $y + DQ \geq$ $-y + EQ \leq$
	0	0	≥ 0	0	0	≥ 0	0	Variable Relaxes constraint case 3	$\max ox^{b/}$ $-y + DQ \geq$ $y + EQ \leq$
	0	≥ 0	0	$\geq 0^{c/}$	$\geq 0^{c/}$	0	≥ 0	Variable Relaxes constraint case 4	$\max ox^{b/}$ $-y + DQ \geq$ $y + FQ =$ $y + EQ \leq$
Unrestricted	+/-	0	0	0	0	0	0	Unbounded Variable case 1	$\max \pm x^{b/}$

- **a/** PS cases are: The variables which satisfy this condition are:
 1. Unbounded as they contribute to the objective function while satisfying the constraints.
 2. Obviously zero since they consume constraint resources and have a cost in the objective function.
 3. Warning this variable relaxes all constraints in which it appears
 4. Warning this variable relaxes all the equality constraints in which it appears in one direction
- **b/** Here $x(y)$ has a positive objective term and can be increased without ever violating any constraints so $x(y)$ is unbounded.
- **c/** Only one coefficient can be present in the equality rows

Table 3: Conditions When Model Elements Could be Unbounded or Infeasible.**Conditions for Potential Unbounded Variables – Presence of Bounds**

Types of Variables	Sign of Objective in Max Problem	Upper	Lower
$\geq 0^{a/}$	+	None	$—^{b/}$
≤ 0	-	—	None
Unrestricted	+	None	—
Unrestricted	—	—	None

- **a/** If a non negative variable has a positive objective function coefficient without an upper bound, then the variable could be unbounded.
- **b/** Any reasonable value can exist for this item

Conditions for Potential Infeasibility Caused by Bounds on Variables

Types of Variables	Existence of Bounds	
	Lower	Upper
$\geq^{c/} 0$	+	—
≤ 0	—	—
Unrestricted	+	—
Unrestricted	—	—

- **c/** If a nonnegative variable has a positive lower bound then it could cause infeasibility.

Conditions for Potential Infeasibility in Equations

Type of Equations	RHS
$\leq^{d/}$	-
$\geq$	+
$=$	+ or -

- **d/** When a less than or equal equation is present it may not be able to be satisfied if it has a negative RHS.

Table 4: Conditions for Potential Infeasibility or Redundancy in Equations Based on Bounds on Variables.

	TYPE OF CONSTRAINT		PS
	$\leq b$	$\geq b$	
SUM OF THE SMALLEST VALUE ^{a/}	$> b$	—	INFEASIBLE
	—	$> b$	REDUNDANT
SUM OF THE LARGEST VALUE ^{b/}	—	$< b$	INFEASIBLE
	$< b$	—	REDUNDANT

Note:

- **a/** Suppose X_j is bounded with LB_j (lower bound) $\leq X_j \leq UB_j$ (upper bound), and we have the sum evaluated at the lower bounds will be the smallest value which could happen in that sum. If the constraint is $< b$, then if the sum is $> b$, we know that this constraint will never be satisfied. If the constraint is $> b$, and the sum is $> b$, we know that this constraint will not limit any possible X value. Hence, it is redundant.
- **b/** Suppose X_j is bounded as follows, LB_j (lower bound) $\leq X_j \leq UB_j$ (upper bound), and we have the sum evaluated at the upper bounds which is either $> b$ or $< b$, in that sum. If the sum is $< b$, and the constraint holds it $< b$ then we know that this constraint will not limit any possible X value. Hence, it is redundant. If the constraint holds it greater than b , but the sum is $< b$, we know that this constraint will never be satisfied.
- **c/** Thanks to Paul Preckel for bringing these tests to the authors' attention.

5.20.8 Appendix B: GAMSCHK One Page Summary

Invoking GAMSCHKOPTION LP=GAMSCHKKeywords allowed in GCK file

Keyword	Allowed SubKEYWORDS	Brief Description
DISPLAYCR	VARIABLE* INVARIABLE* EQUATION* INEQUATION* INTERSECT++	Displays coefficients of selected variables and equations Indicates variable selections follow Indicates equations are wanted in which selected variables fall Indicates equation selections follow Indicates variables are wanted that fall in selected equations Show coefficients which appear at intersections of selected var/eqn
MATCHIT	VARIABLE* LISTVARIABLE* EQUATION* LISTEQUATION*	List variable and equation names and summarize characteristics Summarizes all variables matching selection statements Lists each variable matching a selection statement Summarizes all equations matching a selection statement Lists each equation matching a selection statement
ANALYSIS		Checks for obvious structural defects
BLOCKLIST		Summarizes characteristics of variable and equation blocks
BLOCKPIC		Generates block level schematics
PICTURE	VARIABLE* INVARIABLE* EQUATION* INEQUATION*	Generates tableau schematics Indicates variable selections follow Indicates equations are wanted in which selected variables fall Indicates equation selections follow Indicates variables are wanted that fall in selected equations
POSTOPT	VARIABLE* INVARIABLE* EQUATION* INEQUATION* INTERSECT++ NOTINSOLUTION++ INSOLUTION++ BINDING++ NONBINDING++	Reconstructs reduced cost and equation activity Indicates variable selections follow Indicates variable selections follow Indicates equation selections follow Indicates variables are wanted that fall in selected equations Show coefficients which appear at intersections of selected var/eqn Only nonzero vars or those with zero reduced cost Only zero vars will be selected Only eqns with zero slack will be computed Only eqns with nonzero slack will be computed
ADVISORY		List potential infeasible and unbounded items
NONOPT	IDENTIFY VERBOSE	Lists potential or actual nonoptimal items Same as ADVISORY but after solution Does POSTOPT computations on nonoptimals

Other Notes

- Items marked above with an * are followed by item selection statements.
- Items marked with ++ modify the types of variables, equations and coefficients selected.
- In item selection an * is a wild card for multiple characters while a . is a wildcard for one character.
- Spaces and capitalization don't matter in any of the input.
- Options file controls scaling, solver choice, nonopt filters and maximum allowed selections.
- Page width is controlled by a PW= keyword but cannot exceed GAMS page width.
- Lines beginning with a ? or a # are treated as comments.

5.20.9 Appendix C: Summary of GAMSCHK Options

Option	Description	Default
CNS	solver for CNS problems	
DESCALE	controls treatment of scaling	part
DNLP	solver for DNLP problems	
EQUBLOCK	maximum number of equation blocks allowed Range: $[-\infty, \infty]$	-5
LEVELFILT	numerical value of exponent on "unbounded levels" Range: $[-5, \infty]$	6
LP	solver for LP problems	
MARGFILT	numerical value of exponent on "infeasible marginals" Range: $[-5, \infty]$	6
MCP	solver for MCP problems	
MINLP	solver for MINLP problems	
MIP	solver for MIP problems	
MPEC	solver for MPEC problems	
NLP	solver for NLP problems	
NOSOLVE	suppresses solution of the problem	
OPTFILE	solver options file number	
RMINLP	solver for RMINLP problems	
RMIP	solver for RMIP problems	
RMPEC	solver for RMPEC problems	
SOLVE	forces solution of the problem	
SOLVERNAME	solver for any problems	
VARBLOCK	maximum number of variable blocks allowed Range: $[-\infty, \infty]$	-5

5.21 GloMIQO

Christodoulos A. Floudas, floudas@titan.princeton.edu; Computer-Aided Systems Laboratory; Department of Chemical and Biological Engineering; Princeton University

Ruth Misener r.misener@imperial.ac.uk; Centre for Process Systems Engineering; Imperial College London

16 April 2013 : GloMIQO 2.2

5.21.1 Introduction

The Global Mixed-Integer Quadratic Optimizer, GloMIQO (*Gló-me-ko*), considers Mixed-Integer Quadratically-Constrained Quadratic Programs [MIQCP](#) of the form [\[175\]](#) [\[176\]](#) [\[181\]](#) :

$$\begin{aligned} \min \quad & x^T \cdot Q_0 \cdot x + a_0 \cdot x \\ \text{s.t.} \quad & b_m^{\text{LO}} \leq x^T \cdot Q_m \cdot x + a_m \cdot x \leq b_m^{\text{UP}} \quad \forall m \in \{1, \dots, M\} \\ & x \in \mathbb{R}^C \times \{0, 1\}^B \times \mathbb{Z}^I \end{aligned} \quad (\text{MIQCP})$$

where C , B , I , and M represent the number of continuous variables, binary variables, integer variables, and constraints, respectively. Note that this model can address quadratic continuous and/or integer terms, as well as bilinear terms of continuous-continuous, integer-continuous, and integer-integer type. We assume that it is possible to infer finite bounds $[x_i^L, x_i^U]$ on the variables participating in nonlinear terms.

Major applications of [MIQCP](#) include quality blending in process networks, separating objects in computational geometry, and portfolio optimization in finance. Specific instantiations of [MIQCP](#) in process networks optimization problems include: pooling problems [\[6\]](#) [\[12\]](#) [\[20\]](#) [\[34\]](#) [\[92\]](#) [\[118\]](#) [\[126\]](#) [\[128\]](#) [\[153\]](#) [\[172\]](#) [\[173\]](#) [\[174\]](#) [\[179\]](#) [\[180\]](#) [\[190\]](#) [\[246\]](#) [\[255\]](#), distillation sequences [\[9\]](#) [\[93\]](#) [\[96\]](#), wastewater treatment and total water systems [\[11\]](#) [\[13\]](#) [\[22\]](#) [\[35\]](#) [\[79\]](#) [\[103\]](#) [\[132\]](#) [\[135\]](#) [\[191\]](#) [\[194\]](#), hybrid energy systems [\[23\]](#) [\[24\]](#) [\[77\]](#), heat exchanger networks [\[58\]](#) [\[95\]](#), reactor-separator-recycle systems [\[145\]](#) [\[146\]](#), separation systems [\[217\]](#), data reconciliation [\[205\]](#), batch processes [\[159\]](#), and crude oil scheduling [\[151\]](#) [\[155\]](#) [\[156\]](#) [\[183\]](#) [\[182\]](#). Computational geometry problems formulated as [MIQCP](#) include: point packing [\[17\]](#) [\[60\]](#), cutting convex shapes from rectangles [\[134\]](#) [\[196\]](#), maximizing the area of a convex polygon [\[19\]](#) [\[21\]](#), and chip layout and compaction [\[73\]](#). Portfolio optimization in financial engineering can also be formulated as [MIQCP](#) [\[167\]](#) [\[199\]](#).

As illustrated in Figure 5.4, GloMIQO responds dynamically to elucidate and exploit special structure within [MIQCP](#). GloMIQO falls broadly into the category of branch-and-bound global optimization because it: generates and solves convex relaxations of the nonconvex [MIQCP](#) that rigorously bound the global solution, finds feasible solutions via local optimization, and divides and conquers the feasible set to generate a sequence of convex relaxations converging to the global optimum [\[97\]](#) [\[94\]](#).

5.21.1.1 Licensing and software requirements

Using GAMS/GloMIQO requires

1. a GloMIQO or ANTIGONE license,
2. a CPLEX license, and
3. a CONOPT or SNOPT license.

GloMIQO may stand alone as a [MIQCP](#) solver; it is also available as a proper subset of the general MINLP solver ANTIGONE and is included with a [GAMS/ANTIGONE](#) license.

Figure 5.4 Given a MIQCP optimization problem, GloMIQO reformulates the model, detects special structure in the reformulated MIQCP, solves the optimization problem, and returns the model with respect to the original problem variables

5.21.1.2 Running GAMS/GloMIQO

GAMS/GloMIQO solves MIQCP, RMIQCP, and QCP models. If GAMS/GloMIQO is not the default solver for these models, it can be called using the following command before the `solve` statement:

```
option miqcp=glomiqo, rmiqcp=glomiqo, qcp=glomiqo;
```

5.21.2 GloMIQO Options

The GloMIQO options match the [GAMS/ANTIGONE options](#).

5.21.3 GloMIQO Algorithmic Features

As illustrated in Figure 5.4, the primary algorithmic features in GloMIQO are [reformulating model input](#), [elucidating special structure](#), and [branch-and-bound global optimization](#) [175] [176] [181] .

5.21.3.1 Reformulating Model Input

While the transformation steps illustrated in Figure 5.5, are implemented generically and applied universally, the reformulations are specifically targeted at enhancing the performance of GloMIQO on process networks problems. GloMIQO effectively transforms modular process networks problems into generalized pooling problems [173] [176] . GloMIQO may also add nonconvex bilinear terms to the model formulation to generate tight Reformulation-Linearization Technique cuts.

5.21.3.2 Elucidating Special Structure

GloMIQO automatically detects: (a) Reformulation-Linearization Technique (RLT) equations that do not add nonlinear terms to [MIQCP](#) and (b) special structure in separable multivariable terms [176] .

GloMIQO considers equation/variable and equation/equation products for generating cuts and improving variable bounding. These RLT equations are updated at every node of the branch-and-bound tree:

Equation/Variable: Products of variable x_i with linear equation m (e.g., $[a_m \cdot x - b_m^{\text{UP}}] \cdot [x_i - x_i^{\text{LO}}] \leq 0$)

Equation/Equation: Products of two linear equations m, n (e.g., $-1 \cdot [a_m \cdot x - b_m^{\text{UP}}] \cdot [a_n \cdot x - b_n^{\text{UP}}] \leq 0$)

The GloMIQO preprocessor will add particularly strong RLT cuts outright the the model formulation. Modelers will significantly improve the performance of GloMIQO by writing linear constraints that can be multiplied together without increasing the number of nonlinear terms.

As depicted in Figure 5.6, GloMIQO generates an undirected graph representation of each individual nonlinear equation m , partitions the equation into separable multivariable terms, and detects special structure including convexity and edge-concavity in the individual multivariable terms [176] .

Figure 5.5 (a) Process networks problems are typically defined as a series of modular units. (b) The GloMIQO variable elimination steps transform the user model. (c) The subsequent bilinear term disaggregation further reformulates the model. The entire process is seamless and unseen by the modeler; GloMIQO reverses all transformations after solving the problem and reports results with respect to the original model in (a).

5.21.3.3 Branch-and-Bound Global Optimization

GloMIQO falls broadly into the category of branch-and-bound global optimization because it: generates and solves convex relaxations of the nonconvex **MIQCP** that rigorously guarantee lower bounds on the global solution, finds feasible solutions via local optimization to bound the global solution from above, and divides and conquers the feasible set to generate a sequence of convex relaxations converging to the global optimum [97] [94] .

GloMIQO **generates convex relaxations** using: termwise McCormick envelopes, low-dimensional edge-concave relaxations, eigenvector projections, piecewise-linear underestimators, outer approximation cuts for convex terms, and an adaptive implementation of the Reformulation-Linearization Technique (RLT) [118] [174] [175] [176] [181] [179] [180] .

GloMIQO **dynamically tightens convex relaxations** with cutting planes derived from edge-concave aggregations, α BB underestimators, and convex terms. Cuts are based on both individual equations and the collection of bilinear terms in **MIQCP** . The branch-and-cut strategies differentiate globally-valid α BB and convex cuts from locally-valid edge-concave cuts. Previously-generated cuts are saved in a pool and applied as appropriate in the branch-and-bound tree.

GloMIQO **searches for feasible solutions** by multistarting an NLP solver.

GloMIQO **reduces the search space** using reliability branching, feasibility-based bounds tightening, optimality-based bounds tightening, RLT-based bounds tightening, and bounds tightening based on all higher-order cuts [175] [176] [181] .

5.22 Gurobi 8

Figure 5.6 (a) Nonlinear equation m is an undirected graph with nodes representing variables and edges representing nonzero coefficients $Q_{m,i,j}$. (b) The equation is divided into separable multivariable terms by detecting disjoint vertex sets. (c) Separable multivariable terms are sum decomposable, so all high-order cuts and every bounding strategy operates on a specific multivariable term. For example, detecting three-dimensional edge-concave aggregations is illustrated in red.

5.22.1 Introduction

The Gurobi suite of optimization products include state-of-the-art simplex and parallel barrier solvers for linear programming (LP) and quadratic programming (QP), parallel barrier solver for quadratically constrained programming (QCP), as well as parallel mixed-integer linear programming (MILP), mixed-integer quadratic programming (MIQP) and mixed-integer quadratically constrained programming (MIQCP) solvers.

The Gurobi MIP solver includes shared memory parallelism, capable of simultaneously exploiting any number of processors and cores per processor. The implementation is deterministic: two separate runs on the same model will produce identical solution paths.

While numerous solving options are available, Gurobi automatically calculates and sets most options at the best values for specific problems. All Gurobi options available through GAMS/Gurobi are summarized at the end of this chapter.

We offer a GAMS/GUROBI link that works in combination with a Gurobi callable library license from Gurobi Optimization Inc. Starting with GAMS distribution 24.7 even demo sized models require a license from Gurobi.

An attempt to use the GAMS/Gurobi solver with a link license that has not been set up properly will result in a licensing error with a message describing the problem. For example, the following message is sent to the log when attempting to solve a model that requires a license:

```
...
--- Executing GUROBI: elapsed 0:00:00.077

Gurobi                24.7.1 r55213 Released Mar 16, 2016 VS8 x86/MS Windows

Gurobi link license.
*** Cannot initialize Gurobi environment.
*** Could be a missing or invalid license. (status=10009|10009)
...
```

An attempt to solve a demo sized model without a Gurobi license installed results in:

```

...
--- Executing GUROBI: elapsed 0:00:00.013

Gurobi                24.7.1 r55213 Released Mar 16, 2016 VS8 x86/MS Windows

GAMS/Gurobi demo requires a Gurobi license from Gurobi Optimization.
*** Cannot initialize Gurobi environment.
*** Could be a missing or invalid license. (status=10009|10009)

```

To make GAMS/Gurobi aware of a Gurobi callable library license an environment variable `GRB_LICENSE_FILE` pointing to license file need to be present. Please consult our [support wiki](#) for details. Moreover, GAMS will use it's own Gurobi DLL/shared library, so the Gurobi license has to be valid for the Gurobi version GAMS uses.

Finally, a bare-bone interface to the LP and MIP solver of Gurobi is available under the name [OSIGUROBI](#). It comes free of charge with any GAMS system.

5.22.2 How to Run a Model with Gurobi

The following statement can be used inside your GAMS program to specify using Gurobi

```
Option LP = Gurobi; { or MIP or RMIP or QCP or MIQCP or RMIQCP }
```

The above statement should appear before the `solve` statement. If Gurobi was specified as the default solver during GAMS installation, the above statement is not necessary.

5.22.3 Overview of GAMS/Gurobi

5.22.3.1 Linear, Quadratic and Quadratic Constrained Programming

Gurobi can solve LP and QP problems using several alternative algorithms, while the only choice for solving QCP is the parallel barrier algorithm. The majority of LP problems solve best using Gurobi's state-of-the-art dual simplex algorithm, while most QP problems solve best using the parallel barrier algorithm. Certain types of LP problems benefit from using the parallel barrier or the primal simplex algorithms, while for some types of QP, the dual or primal simplex algorithm can be a better choice. If you are solving LP problems on a multi-core system, you should also consider using the concurrent optimizer. It runs different optimization algorithms on different cores, and returns when the first one finishes.

GAMS/Gurobi also provides access to the Gurobi infeasibility finder. The infeasibility finder takes an infeasible linear program and produces an irreducibly inconsistent set of constraints (IIS). An IIS is a set of constraints and variable bounds which is infeasible but becomes feasible if any one member of the set is dropped. GAMS/Gurobi reports the IIS in terms of GAMS equation and variable names and includes the IIS report as part of the normal solution listing. The infeasibility finder is activated by the option [IIS](#). Another option for analyzing infeasible model the [FeasOpt](#) option which instructs GAMS/Gurobi to find a minimal feasible relaxation of an infeasible model. See section [Feasible Relaxation](#) for details.

GAMS/Gurobi supports sensitivity analysis (post-optimality analysis) for linear programs which allows one to find out more about an optimal solution for a problem. In particular, objective ranging and constraint ranging give information about how much an objective coefficient or a right-hand-side and variable bounds can change without changing the optimal basis. In other words, they give information about how sensitive the optimal basis is to a change in the objective function or the bounds and right-hand

side. GAMS/Gurobi reports the sensitivity information as part of the normal solution listing. Sensitivity analysis is activated by the option [Sensitivity](#).

The Gurobi presolve can sometimes diagnose a problem as being infeasible *or* unbounded. When this happens, GAMS/Gurobi can, in order to get better diagnostic information, rerun the problem with presolve turned off. The rerun without presolve is controlled by the option [ReRun](#). In default mode only problems that are small (i.e. demo sized) will be rerun.

Gurobi can either presolve a model or start from an advanced basis or primal/dual solution pair. Often the solve from scratch of a presolved model outperforms a solve from an unpresolved model started from an advanced basis/solution. It is impossible to determine a priori if presolve or starting from a given advanced basis/solution without presolve will be faster. By default, GAMS/Gurobi will automatically use an advanced basis or solution from a previous `solve` statement. The GAMS [BRatio](#) option can be used to specify when not to use an advanced basis/solution. The GAMS/Gurobi option [UseBasis](#) can be used to ignore or force a basis/solution passed on by GAMS (it overrides [BRatio](#)). In case of multiple solves in a row and slow performance of the second and subsequent solves, the user is advised to set the GAMS [BRatio](#) option to 1.

5.22.3.2 Mixed-Integer Programming

The methods used to solve pure integer and mixed integer programming problems require dramatically more mathematical computation than those for similarly sized pure linear or quadratic programs. Many relatively small integer programming models take enormous amounts of time to solve.

For problems with discrete variables, Gurobi uses a branch and cut algorithm which solves a series of subproblems, LP subproblems for MILP, QP subproblems for MIQP, and QCP subproblems or LP outer approximation subproblems for MIQCP. Because a single mixed integer problem generates many subproblems, even small mixed integer problems can be very compute intensive and require significant amounts of physical memory.

GAMS/Gurobi supports Special Order Sets of type 1 and type 2 as well as semi-continuous and semi-integer variables.

You can provide a known solution (for example, from a MIP problem previously solved or from your knowledge of the problem) to serve as the first integer solution.

If you specify some or all values for the discrete variables together with GAMS/Gurobi option [MipStart](#), Gurobi will check the validity of the values as an integer-feasible solution. If this process succeeds, the solution will be treated as an integer solution of the current problem.

The Gurobi MIP solver includes shared memory parallelism, capable of simultaneously exploiting any number of processors and cores per processor. The implementation is deterministic: two separate runs on the same model will produce identical solution paths.

5.22.3.3 Feasible Relaxation

The Infeasibility Finder identifies the causes of infeasibility by means of inconsistent set of constraints (IIS). However, you may want to go beyond diagnosis to perform automatic correction of your model and then proceed with delivering a solution. One approach for doing so is to build your model with explicit slack variables and other modeling constructs, so that an infeasible outcome is never a possibility. An automated approach offered in GAMS/Gurobi is known as FeasOpt (for Feasible Optimization) and turned on by parameter [FeasOpt](#) in a GAMS/Gurobi option file.

With the FeasOpt option GAMS/Gurobi accepts an infeasible model and selectively relaxes the bounds and constraints in a way that minimizes a weighted penalty function. In essence, the feasible relaxation

tries to suggest the least change that would achieve feasibility. It returns an infeasible solution to GAMS and marks the relaxations of bounds and constraints with the INFES marker in the solution section of the listing file.

By default all equations are candidates for relaxation and weighted equally but none of the variables can be relaxed. This default behavior can be modified by assigning relaxation preferences to variable bounds and constraints. These preferences can be conveniently specified with the `.feaspref` option. The input value denotes the users willingness to relax a constraint or bound. The larger the preference, the more likely it will be that a given bound or constraint will be relaxed. More precisely, the reciprocal of the specified value is used to weight the relaxation of that constraint or bound. The user may specify a preference value less than or equal to 0 (zero), which denotes that the corresponding constraint or bound must not be relaxed. It is not necessary to specify a unique preference for each bound or range. In fact, it is conventional to use only the values 0 (zero) and 1 (one) except when your knowledge of the problem suggests assigning explicit preferences.

Preferences can be specified through a GAMS/Gurobi solver option file using [dot options](#). The syntax is:

(variable or equation).feaspref(value)

For example, suppose we have a GAMS declaration:

```
Set i /i1*i5/;
Set j /j2*j4/;
variable v(i,j); equation e(i,j);
```

Then, the relaxation preference in the *gurobi.opt* file can be specified by:

```
feasopt 1
v.feaspref          1
v.feaspref('i1',*)  2
v.feaspref('i1','j2') 0

e.feaspref(*,'j1')   0
e.feaspref('i5','j4') 2
```

First we turn the feasible relaxation on. Furthermore, we specify that all variables `v(i,j)` have preference of 1, except variables over set element `i1`, which have a preference of 2. The variable over set element `i1` and `j2` has preference 0. Note that preferences are assigned in a procedural fashion so that preferences assigned later overwrite previous preferences. The same syntax applies for assigning preferences to equations as demonstrated above. If you want to assign a preference to all variables or equations in a model, use the keywords `variables` or `equations` instead of the individual variable and equations names (e.g. `variables.feaspref 1`).

The parameter [FeasOptMode](#) allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter [FeasOptMode](#) indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the relaxation (as a *sum* of required relaxations; as the *number* of constraints and bounds required to be relaxed; as a *sum of the squares* of required relaxations). Please check description of parameter [FeasOptMode](#) for details. Also check example models `feasopt*` in the GAMS Model library.

5.22.3.4 Parameter Tuning Tool

The Gurobi Optimizer provides a wide variety of parameters that allow you to control the operation of the optimization engines. The level of control varies from extremely coarse-grained (e.g., the [Method](#) parameter, which allows you to choose the algorithm used to solve continuous models) to very fine-grained (e.g., the [MarkowitzTol](#) parameter, which allows you to adjust the precise tolerances used during simplex basis factorization). While these parameters provide a tremendous amount of user control, the immense space of possible options can present a significant challenge when you are searching for parameter settings that improve performance on a particular model. The purpose of the Gurobi tuning tool is to automate this search.

The Gurobi tuning tool performs multiple solves on your model, choosing different parameter settings for each, in a search for settings that improve runtime. The longer you let it run, the more likely it is to find a significant improvement.

A number of tuning-related parameters allow you to control the operation of the tuning tool. The most important is probably [TuneTimeLimit](#), which controls the amount of time spent searching for an improving parameter set. Other parameters include [TuneTrials](#) (which attempts to limit the impact of randomness on the result), [TuneResults](#) (which limits the number of results that are returned), and [TuneOutput](#) (which controls the amount of output produced by the tool).

While parameter settings can have a big performance effect for many models, they aren't going to solve every performance issue. One reason is simply that there are many models for which even the best possible choice of parameter settings won't produce an acceptable result. Some models are simply too large and/or difficult to solve, while others may have numerical issues that can't be fixed with parameter changes.

Another limitation of automated tuning is that performance on a model can experience significant variations due to random effects (particularly for MIP models). This is the nature of search. The Gurobi algorithms often have to choose from among multiple, equally appealing alternatives. Seemingly innocuous changes to the model (such as changing the order of the constraint or variables), or subtle changes to the algorithm (such as modifying the random number seed) can lead to different choices. Often times, breaking a single tie in a different way can lead to an entirely different search. We've seen cases where subtle changes in the search produce 100X performance swings. While the tuning tool tries to limit the impact of these effects, the final result will typically still be heavily influenced by such issues.

The bottom line is that automated performance tuning is meant to give suggestions for parameters that could produce consistent, reliable improvements on your models. It is not meant to be a replacement for efficient modeling or careful performance testing.

5.22.3.5 Compute Server

The Gurobi Compute Server allows you to use one or more servers to offload all of your Gurobi computations.

Gurobi compute servers support queuing and load balancing. You can set a limit on the number of simultaneous jobs each compute server will run. When this limit has been reached, subsequent jobs will be queued. If you have multiple compute servers, the current job load is automatically balanced among the available servers. By default, the Gurobi job queue is serviced in a First-In, First-Out (FIFO) fashion. However, jobs can be given different priorities ([CSPriority](#)). Jobs with higher priorities are then selected from the queue before jobs with lower priorities.

Gurobi Compute Server licenses and software are not included in GAMS/Gurobi. Contact support@gams.com to inquire about the software and license. Relevant options are [ComputeServer](#) and options starting with CS.

5.22.3.6 Distributed Parallel Algorithms

Gurobi Optimizer implements a number of distributed algorithms that allow you to use multiple machines to solve a problem faster. Available distributed algorithms are:

- A **distributed MIP solver**, which allows you to divide the work of solving a single MIP model among multiple machines. A manager machine passes problem data to a set of worker machines in order to coordinate the overall solution process.
- A **distributed concurrent solver**, which allows you to use multiple machines to solve an LP or MIP model. Unlike the distributed MIP solver, the concurrent solver doesn't divide the work associated with solving the problem among the machines. Instead, each machine uses a different strategy to solve the whole problem, with the hope that one strategy will be particularly effective and will finish much earlier than the others. For some problems, this concurrent approach can be more effective than attempting to divide up the work.
- **Distributed parameter tuning**, which automatically searches for parameter settings that improve performance on your optimization model. Tuning solves your model with a variety of parameter settings, measuring the performance obtained by each set, and then uses the results to identify the settings that produce the best overall performance. The distributed version of tuning performs these trials on multiple machines, which makes the overall tuning process run much faster.

These distributed parallel algorithms are designed to be almost entirely transparent to the user. The user simply modifies a few parameters, and the work of distributing the computation to multiple machines is handled behind the scenes by Gurobi.

5.22.3.6.1 Specifying the Worker Pool Once you've set up a set of one or more distributed workers, you should list at least one of their names in the [WorkerPool](#) parameter. You can provide either machine names or IP addresses, and they should be comma-separated.

You can provide the worker access password through the [WorkerPassword](#) parameter. All servers in the worker pool must have the same access password.

5.22.3.6.2 Requesting Distributed Algorithms Once you've set up the worker pool through the appropriate parameters, the last step to use a distributed algorithm is to set the [TuneJobs](#), [ConcurrentJobs](#), or [DistributedMIPJobs](#) parameter. These parameters are used to indicate how many distinct tuning, concurrent, or distributed MIP jobs should be started on the available workers.

If some of the workers in your worker pool are running at capacity when you launch a distributed algorithm, the algorithm won't create queued jobs. Instead, it will launch as many jobs as it can (up to the requested value), and it will run with these jobs.

These distributed algorithms have been designed to be nearly indistinguishable from the single machine versions. Our hope is that, if you know how to use the single machine version, you'll find it straightforward to use the distributed version. The distributed algorithms respect all of the usual parameters. For distributed MIP, you can adjust strategies, adjust tolerances, set limits, etc. For concurrent MIP, you can allow Gurobi to choose the settings for each machine automatically or specify a set of options. For distributed tuning, you can use the usual tuning parameters, including [TuneTimeLimit](#), [TuneTrails](#), and [TuneOutput](#).

There are a few things to be aware of when using distributed algorithms, though. One relates to relative machine performance. Distributed algorithms work best if all of the workers give very similar performance. For example, if one machine in your worker pool were much slower than the others in a distributed tuning run, any parameter sets tested on the slower machine would appear to be less effective than if they were run on a faster machine. Similar considerations apply for distributed MIP and distributed concurrent. We

strongly recommend that you use machines with very similar performance. Note that if your machines have similarly performing cores but different numbers of cores, we suggest that you use the [Threads](#) parameter to make sure that all machines use the same number of cores.

Logging for distributed MIP is very similar to the standard MIP logging. The main differences are in the progress section. The header for the standard MIP logging looks like this:

Nodes		Current Node		Objective Bounds		Work
Expl Unexpl		Obj Depth IntInf		Incumbent BestBd Gap		It/Node Time

By contrast, the distributed MIP header looks like this:

Nodes		Utilizaiton		Objective Bounds		Work
Expl Unexpl		Active Sync Comm		Incumbent BestBd Gap		It/Node Time

You'll note that columns three through five show different information. In the distributed MIP log, these columns give information about the utilization of the distributed workers, expressed as percentages. The first of these columns shows the fraction of the preceding time period (the time since the previous progress log line) that the workers spent actively processing MIP nodes. The second column shows the time the workers spent waiting for other workers to complete tasks assigned to them. The final column shows the time spent communicating data between machines. The numbers sum to 100%.

Here is an example of a distributed MIP progress log:

Nodes		Utilization		Objective Bounds		Work
Expl Unexpl		Active Sync Comm		Incumbent BestBd Gap		It/Node Time
* 0	-			157344.61033	-	- 0s
* 0	-			41359.940833	-	- 0s
* 0	-			25050.545455	-	- 0s
* 0	-			18150.083886	-	- 0s
* 0	-			14372.871258	-	- 0s
* 0	-			13725.475382	-	- 0s

4569003 21	57% 2% 41%	11801.1857	11800.6434	0.00%	4.4	18s

One thing you may find in the progress section is that node counts may not increase monotonically. In this example, a solution found at node 261 is reported before a solution found at node 0. Distributed MIP tries to create a single, unified view of node numbers, but with multiple machines processing nodes independently, possibly at different rates, some inconsistencies are inevitable.

Another difference is the line that indicates that the distributed ramp-up phase is complete. At this point, the distributed strategy transitions from a concurrent approach to a distributed approach. The log line indicates which worker was the winner in the concurrent approach. Distributed MIP continues by dividing the partially explored MIP search tree from this worker among all of the workers.

Another difference in the distributed log is in the summary section. The distributed MIP log includes a breakdown of how runtime was spent:

```
Runtime breakdown:
  Active: 13.73s (75%)
  Sync:   1.16s (6%)
  Comm:   3.45s (19%)
```

This is an aggregated view of the utilization data that is displayed in the progress log lines. In this example, the workers spent 75% of runtime actively working on MIP nodes, 6% waiting to synchronize with other workers, and 19% communicating data between machines.

The installation instructions for the Gurobi Remote Services can be found on Gurobi's web page www.gurobi.com.

5.22.3.6.3 Gurobi Instant Cloud An alternative to setting up your own pool of machines is to use the **Gurobi Instant Cloud**. You only need a GAMS/Gurobi link license when you solve your problems in the Gurobi Instant Cloud. The cost for the Gurobi license is paid on a per use basis directly to Gurobi. If you follow through the steps on the Gurobi web site, you eventually get the names of the machines Gurobi has started for you in the cloud. In order to use these machines from GAMS/Gurobi, you need to supply a GAMS/Gurobi option file with the following options (this example has started 4 machines):

```
instantcloud 3d1ecef9-dfad-eff4-b3fa
icsecretkey ae6L23a1Je3+fas
workerpool ec2-54-88-214-0.compute-1.amazonaws.com,ec2-54-88-11-24.compute-1.amazonaws.com
workerpassword 8f30654f
DistributedMIPJobs 4
```

Clearly the values of the options in the previous example are subject to change. Relevant options are **InstantCloud** and options starting with IC.

5.22.3.7 Solution Pool

While the default goal of the Gurobi Optimizer is to find one proven optimal solution to your model, with a possible side-effect of finding other solutions along the way, the solver provides a number of parameters that allow you to change this behavior.

By default, the Gurobi MIP solver will try to find one proven optimal solution to your model. It will typically find multiple sub-optimal solutions along the way, which can be retrieved later. However, these solutions aren't produced in a systematic way. The set of solutions that are found depends on the exact path the solver takes through the MIP search. You could solve a MIP model once, obtaining a set of interesting sub-optimal solutions, and then solve the same problem again with different parameter settings, and find only the optimal solution.

If you'd like more control over how solutions are found and retained, the Gurobi Optimizer has a number of parameters available for this. The first and simplest is [PoolSolutions](#), which controls the size of the solution pool. Changing this parameter won't affect the number of solutions that are found - it simply determines how many of those are retained.

You can use the [PoolSearchMode](#) parameter to control the approach used to find solutions. In its default setting (0), the MIP search simply aims to find one optimal solution. Setting the parameter to 1 causes the MIP search to expend additional effort to find more solutions, but in a non-systematic way. You will get more solutions, but not necessarily the best solutions. Setting the parameter to 2 causes the MIP to do a systematic search for the n best solutions. For both non-default settings, the [PoolSolutions](#) parameter sets the target for the number of solutions to find.

If you are only interested in solutions that are within a certain gap of the best solution found, you can set the [PoolGap](#) parameter. Solutions that are not within the specified gap are discarded.

Obtaining an OPTIMAL optimization return status when using `PoolSearchMode=2` indicates that the MIP solver succeeded in finding the desired number of best solutions, or it proved that the model doesn't have that many distinct feasible solutions. If the solver terminated early (e.g., due to a time limit), you *PoolObjBound* attribute (printed to the log) to evaluate the quality of the solutions that were found. This attribute gives a bound on the objective of any solution that isn't already in the solution pool. The difference between this attribute and `ObjBound` is that the latter gives a bound on the objective for any solution, and which is often looser than `PoolObjBound`. The *PoolObjBound* attribute gives a bound on the objective of undiscovered solutions. Further tree exploration won't find better solutions. You can use this bound to get a count of how many of the n best solutions you found: any solutions whose objective values are at least as good as *PoolObjBound* are among the n best.

5.22.3.7.1 Solution Pool Example Let's continue with a few examples of how these parameters would be used. Imagine that you are solving a MIP model with an optimal (minimization) objective of 100. Further imagine that, using default settings, the MIP solver finds four solutions to this model with objectives 100, 110, 120, and 130.

If you set the [PoolSolutions](#) parameter to 3 and solve the model again, the MIP solver would discard the worst solution and return with 3 solutions in the solution pool. If you instead set the [PoolGap](#) parameter to value 0.2, the MIP solver would discard any solutions whose objective value is worse than 120 (which would also leave 3 solutions in the solution pool).

If you set the [PoolSearchMode](#) parameter to 2 and the [PoolSolutions](#) parameter to 10, the MIP solver would attempt to find the 10 best solutions to the model. An OPTIMAL return status would indicate that either (i) it found the 10 best solutions, or (ii) it found all feasible solutions to the model, and there were fewer than 10. If you also set the [PoolGap](#) parameter to a value of 0.1, the MIP solver would try to find 10 solutions with objective no worse than 110. While this may appear equivalent to asking for 10 solutions and simply ignoring those with objective worse than 110, the solve will typically complete significantly faster with this parameter set, since the solver does not have to expend effort looking for solutions beyond the requested gap.

5.22.3.7.2 Solution Pool Subtleties There are a few subtleties associated with finding multiple solutions that we'll cover now.

Continuous Variables

One subtlety arises when considering multiple solutions for models with continuous variables. Specifically, you may have two solutions that take identical values on the integer variables but where some continuous variables differ. By choosing different points on the line between these two solutions, you actually have an infinite number of choices for feasible solutions to the problem. To avoid this issue, we define two solutions as being equivalent if they take the same values on all integer variables (and on all continuous

variables that participate in SOS constraints). A solution will be discarded if it is equivalent to another solution that is already in the pool.

Optimality Gap

The interplay between the optimality gap ([MIPGap](#) or [MIPGapAbs](#)) and multiple solutions can be a bit subtle. When using the default [PoolSearchMode](#), a non-zero optimality gap indicates that you are willing to allow the MIP solver to declare a solution optimal, even though the model may have other, better solutions. The claim the solver makes upon termination is that no other solution would improve the incumbent objective by more than the optimality gap. Terminating at this point is ultimately a pragmatic choice - we'd probably rather have the true best solution, but the cost of reducing the optimality gap to zero can often be prohibitive.

This pragmatic choice can produce a bit of confusion when finding multiple optimal solutions. Specifically, if you ask for the n best solutions, the optimality gap plays a similar role as it does in the default case, but the implications may be a bit harder to understand. Specifically, a non-zero optimality gap means that you are willing to allow the solver to declare that it has found the n best solutions, even though there may be solutions that are better than those that were returned. The claim in this case is that any solution not among the reported n best would improve on the objective for the worst among the n best by less than the optimality gap.

If you want to avoid this source of potential confusion, you should set the optimality gap to 0 when using `PoolSearchMode=2`.

Logging

If you browse the log from a MIP solve with [PoolSearchMode](#) set to a non-default value, you may see the lower bound on the objective exceed the upper bound. This can't happen with the default `PoolSearchMode` - if you are only looking for one optimal solution, the search is done as soon as the lower bound reaches the upper bound. However, if you are looking for the n best solutions, you have to prove that the model has no solution better than the n -th best. The objective for that n -th solution could be much worse than that of the incumbent. In this situation, the log file will include a line of the form:

```
Optimal solution found at node 123 - now completing solution pool...
```

Distributed MIP

One limitation that we should point out related to multiple solutions is that the distributed MIP solver has not been extended to support non-default [PoolSearchMode](#) settings. Distributed MIP will typically produce many more feasible solutions than non-distributed MIP, but there's no way to ask it to find the n best solutions.

5.22.3.8 Multiple Objectives

While typical optimization models have a single objective function, real-world optimization problems often have multiple, competing objectives. For example, in a production planning model, you may want to both maximize profits and minimize late orders, or in a workforce scheduling application, you may want to both minimize the number of shifts that are short-staffed while also respecting worker's shift preferences.

The main challenge you face when working with multiple, competing objectives is deciding how to manage the tradeoffs between them. Gurobi provides tools that simplify the task: Gurobi allows you to blend multiple objectives, to treat them *hierarchically*, or to combine the two approaches. In a blended approach, you optimize a weighted combination of the individual objectives. In a hierarchical or *lexicographic* approach, you set a priority for each objective, and optimize in priority order. When optimizing for one objective, you only consider solutions that would not degrade the objective values of higher-priority objectives. Gurobi allows you to enter and manage your objectives, to provide weights for a blended approach, or to set priorities for a hierarchical approach. Gurobi will only solve multi-objective models with strictly linear objectives. Moreover, for continuous models, Gurobi will report a primal only solution (not dual information).

Following the workforce application the specifications of the objectives would be done as follows:

```

equations defObj, defNumShifts, defSumPreferences;
variables obj, numShifts, sumPreferences;

defobj..          obj =e= numShifts - 1/100*sumPreferences;
defNumShifts..    numShifts =e= ...;
defSumPreferences.. sumPreferences =e= ...;

model workforce /all/;
solve workforce minimizing obj using mip;

```

With the default setting GUROBI will solve the blended objective. Using the parameter [MultObj](#) GUROBI will use a hierarchical approach. A hierarchical or lexicographic approach assigns a priority to each objective, and optimizes for the objectives in decreasing priority order. At each step, it finds the best solution for the current objective, but only from among those that would not degrade the solution quality for higher-priority objectives. The priority is specified by the absolute value of the objective coefficient in the blended objective function (`defObj`). In the example, the `numShifts` objective with coefficient 1 has higher priority than the `sumPreferences` objective with absolute objective coefficient 1/100. The sign of the objective coefficient determines the direction of the particular objective function. So here `numShifts` will be minimized (same direction as on the `solve` statement) while `sumPreferences` will be maximized. GAMS needs to identify the various objective functions, therefore the objective variables can only appear in the blended objective functions and in the particular objective defining equation.

By default, the hierarchical approach won't allow later objectives to degrade earlier objectives. This behavior can be relaxed through a pair of attributes: [ObjNRelTol](#) and [ObjNAbsTol](#). By setting one of these for a particular objective, you can indicate that later objectives are allowed to degrade this objective by the specified relative or absolute amount, respectively. In our earlier example, if the optimal value for `numShifts` is 100, and if we set [ObjNAbsTol](#) for this objective to 20, then the second optimization step maximizing `sumPreferences` would find the best solution for the second objective from among all solutions with objective 120 or better for `numShifts`. Note that if you modify both tolerances, later optimizations would use the looser of the two values (i.e., the one that allows the larger degradation).

5.22.4 GAMS Options

The following GAMS options are used by GAMS/Gurobi:

Option BRatio = x;

Determines whether or not to use an advanced basis. A value of 1.0 causes GAMS to instruct Gurobi not to use an advanced basis. A value of 0.0 causes GAMS to construct a basis from whatever information is available. The default value of 0.25 will nearly always cause GAMS to pass along an advanced basis if a solve statement has previously been executed. This GAMS option is overridden by the GAMS/Gurobi option [UseBasis](#)

Option IterLim = n;

Sets the simplex iteration limit. Simplex algorithms will terminate and pass on the current solution to GAMS. For MIP problems, if the number of the cumulative simplex iterations exceeds the limit, Gurobi will terminate. This GAMS option is overridden by the GAMS/Gurobi option [IterationLimit](#)

Option NodLim = x;

Maximum number of nodes to process for a MIP problem. This GAMS option is overridden by the GAMS/Gurobi option [NodeLimit](#).

Option OptCA = x;

Absolute optimality criterion for a MIP problem. The OptCA option asks Gurobi to stop when

$$|BP - BF| < \text{OptCA}$$

where BF is the objective function value of the current best integer solution while BP is the best possible integer solution. This GAMS option is overridden by the GAMS/Gurobi option [MipGapAbs](#).

Option OptCR = x;

Relative optimality criterion for a MIP problem. Notice that Gurobi uses a different definition than GAMS normally uses. The OptCR option asks Gurobi to stop when

$$|BP - BF| < |BF| * \text{OptCR}$$

where BF is the objective function value of the current best integer solution while BP is the best possible integer solution. The GAMS definition is:

$$|BP - BF| < |BP| * \text{OptCR}$$

This GAMS option is overridden by the GAMS/Gurobi option [MipGap](#).

Option ResLim = x;

Sets the time limit in seconds. The algorithm will terminate and pass on the current solution to GAMS. Gurobi measures time in wall time on all platforms. Some other GAMS solvers measure time in CPU time on some Unix systems. This GAMS option is overridden by the GAMS/Gurobi option [TimeLimit](#).

Option SysOut = On;

Will echo Gurobi messages to the GAMS listing file. This option may be useful in case of a solver failure.

ModelName.Cutoff = x;

Cutoff value. When the branch and bound search starts, the parts of the tree with an objective worse than x are deleted. This can sometimes speed up the initial phase of the branch and bound algorithm. This GAMS option is overridden by the GAMS/Gurobi option [Cutoff](#).

ModelName.OptFile = 1;

Instructs GAMS/Gurobi to read the option file. The name of the option file is `gurobi.opt`.

ModelName.PriorOpt = 1;

Instructs GAMS/Gurobi to use the priority branching information passed by GAMS through variable suffix values `variable.prior`.

5.22.5 Summary of GUROBI Options

5.22.5.1 Termination options

Option	Description	Default
bariterlimit	Limits the number of barrier iterations performed	infinity
cutoff	Sets a target objective value	0
iterationlimit	Limits the number of simplex iterations performed	infinity
nodelimit	Limits the number of MIP nodes explored	maxdouble
solutionlimit	Limits the number of feasible solutions found	maxint
timelimit	Limits the total time expended in seconds	GAMS reslim

5.22.5.2 Tolerance options

Option	Description	Default
barconvtol	Controls barrier termination	1e-8
barqcpconvtol	Convergence tolerance for the barrier algorithm when solving a QCP	1e-6
feasibilitytol	Primal feasibility tolerance	1e-6
intfeastol	Integer feasibility tolerance	1e-5
markowitztol	Threshold pivoting tolerance	0.0078125
mipgap	Relative MIP optimality gap	GAMS optcr
mipgapabs	Absolute MIP optimality gap	GAMS optca
optimalitytol	Dual feasibility tolerance	1e-6
psdtol	limit on the amount of diagonal perturbation	1e-6

5.22.5.3 Simplex options

Option	Description	Default
normadjust	Pricing norm variants	-1
objscale	Objective coefficients scaling	0
perturbvalue	Magnitude of simplex perturbation when required	0.0002
quad	Quad precision computation in simplex	-1
scaleflag	Enables or disables model scaling	1
sifting	Sifting within dual simplex	-1
siftmethod	LP method used to solve sifting sub-problems	-1
simplexpricing	Determines variable pricing strategy	-1

5.22.5.4 Barrier options

Option	Description	Default
barcorrectors	Limits the number of central corrections performed in each barrier iteration	-1
barhomogeneous	Homogeneous barrier algorithm selection	-1
barorder	Chooses the barrier sparse matrix fill-reducing algorithm	-1
crossover	Determines the crossover strategy used to transform the barrier solution into a basic solution	-1
crossoverbasis	Determines the initial basis construction strategy for crossover	0
qcpdual	Determines whether dual variable values are computed for QCP models	1

5.22.5.5 MIP options

Option	Description	Default
bestbdstop	Objective bound to stop optimization	maxdouble
bestobjstop	Objective value to stop optimization	mindouble
branchdir	Determines which child node is explored first in the branch-and-cut search	0
cliquecuts	Controls clique cut generation	-1
concurrentjobs	Distributed concurrent MIP job count	0
concurrentmip	Enables the concurrent MIP solver	1
covercuts	Controls cover cut generation	-1
cutaggpases	Maximum number of aggregation passes during cut generation	-1
cutpasses	Maximum number of cutting plane passes performed during root cut generation	-1
cuts	Global cut generation control	-1
degenmoves	Degenerate simplex moves	-1
disconnected	Disconnected component strategy	-1
distributedmipjobs	Distributed MIP job count	0
fixoptfile	Option file for fixed problem optimization	
flowcovercuts	Controls flow cover cut generation	-1
flowpathcuts	Controls flow path cut generation	-1
gomorypasses	Maximum number of Gomory cut passes	-1
gubcovercuts	Controls GUB cover cut generation	-1
heuristics	Controls the amount of time spent in MIP heuristics	0.05
impliedcuts	Controls implied bound cut generation	-1
improvestartgap	Optimality gap at which the MIP solver resets a few MIP parameters	maxdouble
improvestartnodes	Solution improvement strategy control	maxdouble
improvestarttime	Elapsed time after which the MIP solver resets a few MIP parameters	maxdouble

Option	Description	Default
infproofcuts	Infeasibility proof cut generation	-1
.lazy	Lazy constraints value	0
lazyconstraints	Indicator to use lazy constraints	0
minrelnodes	Number of nodes to explore in the Minimum Relaxation heuristic	0
mipfocus	Controls the focus of the MIP solver	0
mipsepcuts	Controls MIP separation cut generation	-1
mipstart	Use mip starting values	0
miqcpmethod	Determines whether outer approximation is used to solve an MIQCP model.	-1
mircuts	Controls MIR cut generation	-1
modkcuts	Controls the generation of mod-k cuts	-1
networkcuts	Controls network cut generation	-1
nodefiledir	Nodefile directory	.
nodefilestart	Nodefile starting indicator	maxdouble
nodemethod	Algorithm used to solve node relaxations in a MIP model	1
norelheuristic	No relaxation heuristic attempts to find feasible solutions without solving root relaxation	0
.partition	Variable partition value	0
partitionplace	Controls where the partition heuristic runs	0
poolgap	Maximum gap for stored solutions	maxdouble
poolsearchmode	Selects different modes for exploring the MIP search tree	0
poolsolutions	Number of MIP solutions to store	10
presos1bigm	Threshold for SOS1-to-binary reformulation	-1
presos2bigm	Threshold for SOS2-to-binary reformulation	0
presparsify	Enables the presolve sparsify reduction for MIP models	0
.prior	Branching priorities	1
pumppasses	Number of passes of the feasibility pump heuristic	0
rins	Frequency of the RINS heuristic	-1
solnpool	Controls export of alternate MIP solutions	
solvefixed	Indicator for solving the fixed problem for a MIP to get a dual solution	1
startnodelimit	Limit MIP start sub-MIP nodes	-1
strongegcuts	Strong-CG cut generation	-1
submipcuts	Controls the generation of sub-MIP cutting planes	-1
submipnodes	Limits the number of nodes explored by the heuristics	500

Option	Description	Default
symmetry	Controls MIP symmetry detection	-1
varbranch	Controls the branch variable selection strategy	-1
zerohalfcuts	Controls zero-half cut generation	-1
zeroobjnodes	Number of nodes to explore in the zero objective heuristic	0

5.22.5.6 Other options

Option	Description	Default
aggfill	Controls the amount of fill allowed during presolve aggregation	10
aggregate	Enables or disables aggregation in presolve	1
computeserver	List of Gurobi compute servers	
csgroup	The name of the Compute Server group	
cspassword	Password for Gurobi compute servers	
csport	The port number used to connect to the compute server	-1
cspriority	Job priority on the compute server	0
csrout	The router for a Compute Server cluster	
cstimeoutfrac	Fraction of reslim that job will wait to reach front of the compute server queue	0.1
cstlsinsecure	Indicates whether to use insecure mode in the TLS (Transport Layer Security)	0
displayinterval	Controls the frequency at which log lines are printed in seconds	5
feasopt	Computes a minimum-cost relaxation to make an infeasible model feasible	0
feasoptmode	Mode of FeasOpt	0
.feaspref	feasibility preference	1
freegamsmodel	Preserves memory by dumping the GAMS model instance representation temporarily to disk	0
.genconstrtype	General constraint type	0
icpool	The machine pool for Gurobi Instant Cloud	
icpriority	The priority of the job in the Gurobi Instant Cloud	0
icsecretkey	The secret key for your Gurobi Instant Cloud license	
iis	Run the Irreducible Inconsistent Subsystem (IIS) finder if the problem is infeasible	0
iismethod	Controls use of IIS method	-1
instantcloud	The access ID for your Gurobi Instant Cloud license	
kappa	Display approximate condition number estimates for the optimal simplex basis	0
kappaexact	Display exact condition number estimates for the optimal simplex basis	0

Option	Description	Default
method	Algorithm used to solve continuous models	-1
multiobjmethod	Method used for multi-objective solves	-1
multiobjpre	Initial presolve level on multi-objective models	-1
multobj	Controls the hierarchical optimization of multiple objectives	0
names	Indicator for loading names	1
numericfocus	Set the numerical focus	0
objnabstol	Allowable absolute degradation for objective	
objnreltol	Allowable relative degradation for objective	
precrush	Presolve constraint option	0
predeprow	Controls the presolve dependent row reduction	-1
predual	Controls whether presolve forms the dual of a continuous model	-1
premiqcpform	Determines the format of the presolved version of an MIQCP model	-1
premiqpmethod	Transformation presolve performs on MIQP models	-1
prepasses	Controls the number of passes performed by presolve	-1
preqlinearize	Controls linearization of Q matrices in the quadratic constraints or a quadratic objective	-1
presolve	Controls the presolve level	-1
printoptions	List values of all options to GAMS listing file	0
readparams	Read Gurobi parameter file	
rerun	Resolve without presolve in case of unbounded or infeasible	0
seed	Random number seed	0
sensitivity	Provide sensitivity information	0
threads	Controls the number of threads to apply to parallel MIP or Barrier	GAMS threads
tunecriterion	Tuning criterion	-1
tunejobs	Distributed tuning job count	0
tuneoutput	Tuning output level	2
tunerresults	Number of improved parameter sets returned	1
tunetimelimit	Time limit for tuning	-1
tunetrials	Perform multiple runs on each parameter set to limit the effect of random noise	2
tuning	Parameter Tuning	
usebasis	Use basis from GAMS	GAMS bratio
varhint	Guide heuristics and branching through variable hints	0
workerpassword	Compute server password Pool of compute servers to use for distributed algorithms	

Option	Description	Default
workerpool	Pool of compute servers to use for distributed algorithms	
workerport	Non-default port number for distributed workers	-1
writeparams	Write Gurobi parameter file	
writeprob	Save the problem instance	

5.22.5.7 The GAMS/Gurobi Options File

The GAMS/Gurobi options file consists of one option or comment per line. An asterisk (*) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by any amount of white space (blanks or tabs).

Following is an example options file *gurobi.opt*.

```
simplexpricing 3
method 0
```

It will cause Gurobi to use quick-start steepest edge pricing and will use the primal simplex algorithm.

5.22.6 GAMS/Gurobi Log File

Gurobi reports its progress by writing to the GAMS log file as the problem solves. Normally the GAMS log file is directed to the computer screen.

The log file shows statistics about the presolve and continues with an iteration log.

For the simplex algorithms, each log line starts with the iteration number, followed by the objective value, the primal and dual infeasibility values, and the elapsed wall clock time. The dual simplex uses a bigM approach for handling infeasibility, so the objective and primal infeasibility values can both be very large during phase I. The frequency at which log lines are printed is controlled by the [DisplayInterval](#) option. By default, the simplex algorithms print a log line roughly every five seconds, although log lines can be delayed when solving models with particularly expensive iterations.

The simplex screen log has the following appearance:

```
Presolve removed 977 rows and 1539 columns
Presolve changed 3 inequalities to equalities
Presolve time: 0.078000 sec.
Presolved: 1748 Rows, 5030 Columns, 32973 Nonzeros
```

Iteration	Objective	Primal Inf.	Dual Inf.	Time
0	3.8929476e+31	1.200000e+31	1.485042e-04	0s
5624	1.1486966e+05	0.000000e+00	0.000000e+00	2s

```
Solved in 5624 iterations and 1.69 seconds
Optimal objective 1.148696610e+05
```

The barrier algorithm log file starts with barrier statistics about dense columns, free variables, nonzeros in AA' and the Cholesky factor matrix, computational operations needed for the factorization, memory estimate and time estimate per iteration. Then it outputs the progress of the barrier algorithm in iterations with the primal and dual objective values, the magnitude of the primal and dual infeasibilities and the magnitude of the complementarity violation. After the barrier algorithm terminates, by default, Gurobi will perform crossover to obtain a valid basic solution. It first prints the information about pushing the dual and primal superbasic variables to the bounds and then the information about the simplex progress until the completion of the optimization.

The barrier screen log has the following appearance:

```
Presolve removed 2394 rows and 3412 columns
Presolve time: 0.09s
Presolved: 3677 Rows, 8818 Columns, 30934 Nonzeros
```

```
Ordering time: 0.20s
```

```
Barrier statistics:
```

```
Dense cols : 10
Free vars  : 3
AA' NZ     : 9.353e+04
Factor NZ  : 1.139e+06 (roughly 14 MBytes of memory)
Factor Ops : 7.388e+08 (roughly 2 seconds per iteration)
```

Iter	Objective		Residual		Compl	Time
	Primal	Dual	Primal	Dual

For MIP problems, the Gurobi solver prints regular status information during the branch and bound search. The first two output columns in each log line show the number of nodes that have been explored so far in the search tree, followed by the number of nodes that remain unexplored. The next three columns provide information on the most recently explored node in the tree. The solver prints the relaxation objective value for this node, followed by its depth in the search tree, followed by the number of integer variables with fractional values in the node relaxation solution. The next three columns provide information on the progress of the global MIP bounds. They show the objective value for the best known integer feasible solution, the best bound on the value of the optimal solution, and the gap between these lower and upper bounds. Finally, the last two columns provide information on the amount of work performed so far. The first column gives the average number of simplex iterations per explored node, and the next column gives the elapsed wall clock time since the optimization began.

At the default value for option `DisplayInterval`, the MIP solver prints one log line roughly every five seconds. Note, however, that log lines are often delayed in the MIP solver due to particularly expensive nodes or heuristics.

```
Presolve removed 12 rows and 11 columns
Presolve tightened 70 bounds and modified 235 coefficients
Presolve time: 0.02s
Presolved: 114 Rows, 116 Columns, 424 Nonzeros
Objective GCD is 1
```

	Nodes		Current Node			Objective Bounds			Work

5.22.7 Detailed Descriptions of GUROBI Options

aggfill (*integer*): Controls the amount of fill allowed during presolve aggregation ↩

Default: 10

aggregate (*integer*): Enables or disables aggregation in presolve ↩

Default: 1

barconvtol (*real*): Controls barrier termination [↔](#)

The barrier solver terminates when the relative difference between the primal and dual objective values is less than the specified tolerance.

Default: 1e-8

barcorrectors (*integer*): Limits the number of central corrections performed in each barrier iteration [↔](#)

The default value is chosen automatically, depending on problem characteristics.

Default: -1

barhomogeneous (*integer*): Homogeneous barrier algorithm selection [↔](#)

Determines whether to use the homogeneous barrier algorithm. At the default setting (-1), it is only used when barrier solves a node relaxation for a MIP model. Setting the parameter to 0 turns it off, and setting it to 1 forces it on. The homogeneous algorithm is useful for recognizing infeasibility or unboundedness. It is a bit slower than the default algorithm.

Default: -1

value	meaning
-1	Auto
0	Homogeneous Barrier off
1	Force Homogeneous Barrier on

bariterlimit (*integer*): Limits the number of barrier iterations performed [↔](#)

Default: infinity

barorder (*integer*): Chooses the barrier sparse matrix fill-reducing algorithm [↔](#)

Default: -1

value	meaning
-1	Auto
0	Approximate Minimum Degree ordering
1	Nested Dissection ordering

barqcpconvtol (*real*): Convergence tolerance for the barrier algorithm when solving a QCP [↔](#)

When solving a QCP model, the barrier solver terminates when the relative difference between the primal and dual objective values is less than the specified tolerance. Tightening this tolerance may lead to a more accurate solution, but it may also lead to a failure to converge.

Default: 1e-6

bestbdstop (*real*): Objective bound to stop optimization [↔](#)

Terminates as soon as the engine determines that the best bound on the objective value is at least as good as the specified value.

Default: maxdouble

bestobjstop (*real*): Objective value to stop optimization ↩

Terminate as soon as the engine finds a feasible solution whose objective value is at least as good as the specified value.

Default: `mindouble`

branchdir (*integer*): Determines which child node is explored first in the branch-and-cut search ↩

This option allows more control over how the branch-and-cut tree is explored. Specifically, when a node in the MIP search is completed and two child nodes, corresponding to the down branch and the up branch are created, this parameter allows you to determine whether the MIP solver will explore the down branch first, the up branch first, or whether it will choose the next node based on a heuristic determination of which sub-tree appears more promising.

Default: 0

value	meaning
-1	Always explore the down branch first
0	Automatic
1	Always explore the up branch first

cliquecuts (*integer*): Controls clique cut generation ↩

See the description of the global [Cuts](#) parameter for further information.

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

computeserver (*string*): List of Gurobi compute servers ↩

This option will use the Gurobi compute server facility to solve the model. The value of the option is a comma separated list of IP addresses or computer names of Gurobi compute servers. On the compute servers, a full Gurobi installation (not just GAMS/Gurobi) is required with an appropriate Gurobi compute server license.

concurrentjobs (*integer*): Distributed concurrent MIP job count ↩

Enables distributed concurrent optimization, which can be used to solve LP or MIP models on multiple machines. A value of n causes the solver to create n independent models, using different parameter settings for each. Each of these models is sent to a distributed worker for processing. Optimization terminates when the first solve completes. Use the [WorkerPool](#) parameter to provide a list of available distributed workers.

By default, Gurobi chooses the parameter settings used for each independent solve automatically. The intent of concurrent MIP solving is to introduce additional diversity into the MIP search. By bringing the resources of multiple machines to bear on a single model, this approach can sometimes solve models much faster than a single machine.

Default: 0

concurrentmip (*integer*): Enables the concurrent MIP solver ↔

This parameter enables the concurrent MIP solver. When the parameter is set to value n , the MIP solver performs n independent MIP solves in parallel, with different parameter settings for each. Optimization terminates when the first solve completes. Gurobi chooses the parameter settings used for each independent solve automatically. The intent of concurrent MIP solving is to introduce additional diversity into the MIP search. This approach can sometimes solve models much faster than applying all available threads to a single MIP solve, especially on very large parallel machines.

The concurrent MIP solver divides available threads evenly among the independent solves. For example, if you have 6 threads available and you set ConcurrentMIP to 2, the concurrent MIP solver will allocate 3 threads to each independent solve. Note that the number of independent solves launched will not exceed the number of available threads.

The concurrent MIP solver produces a slightly different log from the standard MIP solver. The log only provides periodic summary information. Each concurrent MIP log line shows the objective for the best feasible solution found by any of the independent solves to that point, the best objective bound proved by any of the independent solves, and the relative gap between these two values. Gurobi also includes node counts from one of the independent solves, as well as elapsed times, to give some indication of forward progress.

Default: 1

covercuts (*integer*): Controls cover cut generation ↔

See the description of the global [Cuts](#) parameter for further information.

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

crossover (*integer*): Determines the crossover strategy used to transform the barrier solution into a basic solution ↔

Use value 0 to disable crossover; the solver will return an interior solution. Other options control whether the crossover algorithm tries to push primal or dual variables to bounds first, and then which simplex algorithm is used once variable pushing is complete. Options 1 and 2 push dual variables first, then primal variables. Option 1 finishes with primal, while option 2 finishes with dual. Options 3 and 4 push primal variables first, then dual variables. Option 3 finishes with primal, while option 4 finishes with dual. The default value of -1 chooses automatically.

Default: -1

crossoverbasis (*integer*): Determines the initial basis construction strategy for crossover ↔

The default value (0) chooses an initial basis quickly. A value of 1 can take much longer, but often produces a much more numerically stable start basis.

Default: 0

csgroup (*string*): The name of the Compute Server group ↩

cspassword (*string*): Password for Gurobi compute servers ↩

csport (*integer*): The port number used to connect to the compute server ↩

You should use the default value, which indicates that the default port should be used, unless your server administrator has changed our recommended port settings.

Default: -1

cspriority (*integer*): Job priority on the compute server ↩

Gurobi compute servers support job priorities. You can assign an integer priority between -100 and 100 to each job (the default is 0). When choosing among queued jobs, the compute server will run the highest priority job first. Note that servers will never preempt running jobs.

We have chosen to give priority 100 a special meaning. A priority 100 job will start immediately, even if this means that a server will exceed its job limit. You should be cautious with priority 100 jobs, since submitting too many at once could lead to very high server loads, which could lead to poor performance and even crashes in extreme cases.

Default: 0

csrouter (*string*): The router for a Compute Server cluster ↩

cstimeoutfrac (*real*): Fraction of reslim that job will wait to reach front of the compute server queue ↩

If the compute servers are all busy, new jobs will be queued. This option controls the fraction of the available time (ResLim) that one is willing to wait in the queue before the optimization can start. This waiting time does not count towards the actual time available to the optimizer.

Default: 0.1

cstlsinsecure (*integer*): Indicates whether to use insecure mode in the TLS (Transport Layer Security) ↩

Default: 0

cutaggpases (*integer*): Maximum number of aggregation passes during cut generation ↩

A non-negative value indicates the maximum number of constraint aggregation passes performed during cut generation. See the description of the global [Cuts](#) parameter for further information.

Default: -1

cutoff (*real*): Sets a target objective value ↩

Optimization will terminate if the engine determines that the optimal objective value for the model is worse than the specified cutoff. This option overwrites the GAMS cutoff option.

Default: 0

cutpasses (*integer*): Maximum number of cutting plane passes performed during root cut generation ↔

Default: -1

cuts (*integer*): Global cut generation control ↔

The parameters, **Cuts**, **CliqueCuts**, **CoverCuts**, **FlowCoverCuts**, **FlowPathCuts**, **GUBCoverCuts**, **ImpliedCuts**, **InfProofCuts**, **MIPSepCuts**, **MIRCuts**, **ModKCuts**, **NetworkCuts**, **GomoryPasses**, **StrongCGCuts**, **SubMIPCuts**, **CutAggPasses** and **ZeroHalfCuts**, affect the generation of MIP cutting planes. In all cases except **GomoryPasses** and **CutAggPasses**, a value of -1 corresponds to an automatic setting, which allows the solver to determine the appropriate level of aggressiveness in the cut generation. Unless otherwise noted, settings of 0, 1, and 2 correspond to no cut generation, conservative cut generation, or aggressive cut generation, respectively. The **Cuts** parameter provides global cut control, affecting the generation of all cuts. This parameter also has a setting of 3, which corresponds to very aggressive cut generation. The other parameters override the global **Cuts** parameter (so setting **Cuts** to 2 and **CliqueCuts** to 0 would generate all cut types aggressively, except clique cuts which would not be generated at all. Setting **Cuts** to 0 and **GomoryPasses** to 10 would not generate any cuts except Gomory cuts for 10 passes).

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive
3	Very aggressive

degenmoves (*integer*): Degenerate simplex moves ↔

Limits degenerate simplex moves. These moves are performed to improve the integrality of the current relaxation solution. By default, the algorithm chooses the number of moves to perform automatically.

Changing the value of this parameter can help performance in cases where an excessive amount of time is spent after the initial root relaxation has been solved but before the cut generation process or the root heuristics have started.

Default: -1

disconnected (*integer*): Disconnected component strategy ↔

A MIP model can sometimes be made up of multiple, completely independent sub-models. This parameter controls how aggressively we try to exploit this structure. A value of 0 ignores this structure entirely, while larger values try more aggressive approaches. The default value of -1 chooses automatically. This only affects mixed integer programming (MIP) models.

Default: -1

value	meaning
-1	Auto
0	Ignores structure entirely
1	Conservative
2	Aggressive

displayinterval (*integer*): Controls the frequency at which log lines are printed in seconds ↔

Default: 5

distributedmipjobs (*integer*): Distributed MIP job count ↔

Enables distributed MIP. A value of n causes the MIP solver to divide the work of solving a MIP model among n machines. Use the [WorkerPool](#) parameter to provide the list of available machines.

Default: 0

feasibilitytol (*real*): Primal feasibility tolerance ↔

All constraints must be satisfied to a tolerance of **FeasibilityTol**.

Range: [1e-9, 1e-2]

Default: 1e-6

feasopty (*boolean*): Computes a minimum-cost relaxation to make an infeasible model feasible ↔

With **Feasopt** turned on, a minimum-cost relaxation of the right hand side values of constraints or bounds on variables is computed in order to make an infeasible model feasible. It marks the relaxed right hand side values and bounds in the solution listing.

Several options are available for the metric used to determine what constitutes a minimum-cost relaxation which can be set by option [FeasOptMode](#).

Feasible relaxations are available for all problem types.

Default: 0

value	meaning
0	Turns Feasible Relaxation off
1	Turns Feasible Relaxation on

feasoptymode (*integer*): Mode of FeasOpt ↔

The parameter **FeasOptMode** allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter **FeasOptMode** indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the minimality of the relaxation (as a *sum* of required relaxations; as the *number* of constraints and bounds required to be relaxed; as a *sum of the squares* of required relaxations).

Default: 0

value	meaning
0	Minimize sum of relaxations Minimize the sum of all required relaxations in first phase only

value	meaning
1	Minimize sum of relaxations and optimize Minimize the sum of all required relaxations in first phase and execute second phase to find optimum among minimal relaxations
2	Minimize number of relaxations Minimize the number of constraints and bounds requiring relaxation in first phase only
3	Minimize number of relaxations and optimize Minimize the number of constraints and bounds requiring relaxation in first phase and execute second phase to find optimum among minimal relaxations
4	Minimize sum of squares of relaxations Minimize the sum of squares of required relaxations in first phase only
5	Minimize sum of squares of relaxations and optimize Minimize the sum of squares of required relaxations in first phase and execute second phase to find optimum among minimal relaxations

.feaspref (*real*): feasibility preference ↔

You can express the costs associated with relaxing a bound or right hand side value during a **FeasOpt** run through the **.feaspref** option. The syntax for **dot options** is explained in the Introduction chapter of the Solver Manual. The input value denotes the users willingness to relax a constraint or bound. More precisely, the reciprocal of the specified value is used to weight the relaxation of that constraint or bound. The user may specify a preference value less than or equal to 0 (zero), which denotes that the corresponding constraint or bound must not be relaxed.

Default: 1

fixoptfile (*string*): Option file for fixed problem optimization ↔

flowcovercuts (*integer*): Controls flow cover cut generation ↔

See the description of the global **Cuts** parameter for further information.

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

flowpathcuts (*integer*): Controls flow path cut generation ↔

See the description of the global **Cuts** parameter for further information.

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

freegamsmodel (*boolean*): Preserves memory by dumping the GAMS model instance representation temporarily to disk ↵

Default: 0

.genconstrtype (*integer*): General constraint type ↵

Mathematical programming has traditionally defined a set of fundamental constraint types: variable bound constraints, linear constraints, quadratic constraints, integrality constraints, and SOS constraints. These are typically treated directly by the underlying solver (although not always), and are fundamental to the overall algorithm.

Gurobi accepts a number of additional constraint types, which we collectively refer to as *general constraints*. These are typically not treated directly by the solver. Rather, they are transformed by presolve into mathematically equivalent sets of constraints (and variables), chosen from among the fundamental types listed above. These general constraints are provided as a convenience to users. If such constraints appear in your model, but if you prefer to reformulate them yourself using fundamental constraint types instead, you can certainly do so. However, note that Gurobi can sometimes exploit information contained in the other constraints in the model to build a more efficient formulation than what you might create. Gurobi does not allow general logical constraints but needs the constraint with a single operator (either *max* or *min* or ...). In order to pass the general constraint type to Gurobi we interpret a linear constraint plus the value of the **GenConstrType** option. Such a linear constraint has a resultant variable (r or rb) on the left hand side of =E=) and the variables involved in the operation on the right hand side:

MAX constraint:

```
eqMax.. r =e= max(x1,x2,x3,c);
```

is represented in the following form:

```
eqMax.. r =e= x1+x2+x3+c;
```

with GAMS/GUROBI option `eqMax.GenConstrType=1`.

MIN constraint:

```
eqMin.. r =e= min(x1,x2,x3,c);
```

is represented in the following form:

```
eqMin.. r =e= x1+x2+x3+c;
```

with GAMS/GUROBI option `eqMin.GenConstrType=2`.

ABS constraint:

```
eqAbs.. r =e= abs(x1);
```

is represented in the following form:

```
eqAbs.. r =e= x1;
```

with GAMS/GUROBI option `eqAbs.GenConstrType=3`.

AND constraint:

```
eqAnd.. br =e= b1 and b2 and b3 and b4;
```

is represented in the following form:

```
eqAnd.. br =e= b1+b2+b3+b4;
```

with GAMS/GUROBI option `eqAnd.GenConstrType=4`.

OR constraint:

```
eqOr.. br =e= b1 or b2 or b3 or b4;
```

is represented in the following form:

```
eqOr.. br =e= b1+b2+b3+b4;
```

with GAMS/GUROBI option `eqOr.GenConstrType=5`.

Note that for the AND and OR constraint the resultant variable needs to be a binary variable. The default value for parameter `GenConstrType` of a constraint is 0 marking it as a regular constraint (linear or quadratic).

Default: 0

gomorypasses (*integer*): Maximum number of Gomory cut passes [↔](#)

A non-negative value indicates the maximum number of Gomory cut passes performed. See the description of the global [Cuts](#) parameter for further information.

Default: -1

gubcovercuts (*integer*): Controls GUB cover cut generation [↔](#)

See the description of the global [Cuts](#) parameter for further information.

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

heuristics (*real*): Controls the amount of time spent in MIP heuristics [↔](#)

Larger values produce more and better feasible solutions, at a cost of slower progress in the best bound.

Range: [0, 1]

Default: 0.05

icpool (*string*): The machine pool for Gurobi Instant Cloud [↔](#)

icpriority (*integer*): The priority of the job in the Gurobi Instant Cloud [↔](#)

Default: 0

icsecretkey (*string*): The secret key for your Gurobi Instant Cloud license ↩

iis (*boolean*): Run the Irreducible Inconsistent Subsystem (IIS) finder if the problem is infeasible ↩

Default: 0

value	meaning
0	Do not run the IIS finder
1	Run the IIS finder

iismethod (*integer*): Controls use of IIS method ↩

Chooses the IIS method to use. Method 0 is often faster, while method 1 can produce a smaller IIS. The default value of -1 chooses automatically.

Default: -1

impliedcuts (*integer*): Controls implied bound cut generation ↩

See the description of the global [Cuts](#) parameter for further information.

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

improvestartgap (*real*): Optimality gap at which the MIP solver resets a few MIP parameters ↩

The MIP solver can change parameter settings in the middle of the search in order to adopt a strategy that gives up on moving the best bound and instead devotes all of its effort towards finding better feasible solutions. This parameter allows you to specify an optimality gap at which the MIP solver will switch to this strategy. For example, setting this parameter to 0.1 will cause the MIP solver to switch once the relative optimality gap is smaller than 0.1.

Default: `maxdouble`

improvestartnodes (*real*): Solution improvement strategy control ↩

The MIP solver can change parameter settings in the middle of the search in order to adopt a strategy that gives up on moving the best bound and instead devotes all of its effort towards finding better feasible solutions. This parameter allows you to specify the node count at which the MIP solver switches to a solution improvement strategy. For example, setting this parameter to 10 will cause the MIP solver to switch strategies once the node count is larger than 10.

Default: `maxdouble`

improvestarttime (*real*): Elapsed time after which the MIP solver resets a few MIP parameters ↩

The MIP solver can change parameter settings in the middle of the search in order to adopt a strategy that gives up on moving the best bound and instead devotes all of its effort towards finding better feasible solutions. This parameter allows you to specify a time limit when the MIP solver will switch to this strategy. For example, setting this parameter to 10 will cause the MIP solver to switch 10 seconds after starting the optimization.

Default: `maxdouble`

infproofcuts (*integer*): Infeasibility proof cut generation [↔](#)

Controls infeasibility proof cut generation. Use 0 to disable these cuts, 1 for moderate cut generation, or 2 for aggressive cut generation. The default -1 value chooses automatically. Overrides the [Cuts](#) parameter.

Default: -1

instantcloud (*string*): The access ID for your Gurobi Instant Cloud license [↔](#)

intfeastol (*real*): Integer feasibility tolerance [↔](#)

An integrality restriction on a variable is considered satisfied when the variable's value is less than `IntFeasTol` from the nearest integer value.

Range: `[1e-9, 1e-1]`

Default: `1e-5`

iterationlimit (*real*): Limits the number of simplex iterations performed [↔](#)

Default: `infinity`

kappa (*boolean*): Display approximate condition number estimates for the optimal simplex basis [↔](#)

Default: 0

value	meaning
0	Do not compute and display approximate condition number
1	Compute and display approximate condition number

kappaexact (*boolean*): Display exact condition number estimates for the optimal simplex basis [↔](#)

Default: 0

value	meaning
0	Do not compute and display exact condition number
1	Compute and display exact condition number

.lazy (*integer*): Lazy constraints value [↔](#)

Determines whether a linear constraint is treated as a lazy constraint. At the beginning of the MIP solution process, any constraint whose Lazy attribute is set to 1, 2, or 3 (the default value is 0) is removed from the model and placed in the lazy constraint pool. Lazy constraints

remain inactive until a feasible solution is found, at which point the solution is checked against the lazy constraint pool. If the solution violates any lazy constraints, the solution is discarded and one or more of the violated lazy constraints are pulled into the active model.

Larger values for this attribute cause the constraint to be pulled into the model more aggressively. With a value of 1, the constraint can be used to cut off a feasible solution, but it won't necessarily be pulled in if another lazy constraint also cuts off the solution. With a value of 2, all lazy constraints that are violated by a feasible solution will be pulled into the model. With a value of 3, lazy constraints that cut off the relaxation solution are also pulled in.

Only affects MIP models. Lazy constraints are only active if option [LazyConstraints](#) is enabled and are specified through the option `.lazy`. The syntax for [dot options](#) is explained in the Introduction chapter of the Solver Manual.

Default: 0

lazyconstraints (*boolean*): Indicator to use lazy constraints [↔](#)

Default: 0

markowitztol (*real*): Threshold pivoting tolerance [↔](#)

Used to limit numerical error in the simplex algorithm. A larger value may avoid numerical problems in rare situations, but it will also harm performance.

Range: [1e-4, 0.999]

Default: 0.0078125

method (*integer*): Algorithm used to solve continuous models [↔](#)

Synonyms: `lpmethod` `rootmethod`

Concurrent optimizers run multiple solvers on multiple threads simultaneously, and choose the one that finishes first. Deterministic concurrent (4) gives the exact same result each time, while concurrent (3) is often faster but can produce different optimal bases when run multiple times. In the current release, the default Automatic (-1) will choose non-deterministic concurrent (3) for an LP, barrier (2) for a QP, and dual (1) for the MIP root node. Only simplex and barrier algorithms are available for continuous QP models. Only primal and dual simplex are available for solving the root of an MIQP model. Only barrier is available for continuous QCP models.

The default setting is rarely significantly slower than the best possible setting, so you generally won't see a big gain from changing this parameter. There are classes of models where one particular algorithm is consistently fastest, though, so you may want to experiment with different options when confronted with a particularly difficult model.

Note that if memory is tight on an LP model, you should consider choosing the dual simplex method (`Method=1`). The default will invoke the concurrent optimizer, which typically consumes a lot more memory than dual simplex alone.

Default: -1

value	meaning
-1	Automatic
0	Primal simplex
1	Dual simplex
2	Barrier
3	Concurrent
4	Deterministic concurrent

minrelnodes (*integer*): Number of nodes to explore in the Minimum Relaxation heuristic [↔](#)

This parameter controls the Minimum Relaxation heuristic that can be useful for finding solutions to MIP models where other strategies fail to find feasible solutions in a reasonable amount of time. This heuristic is only applied at the end of the MIP root, and only when no other root heuristic finds a feasible solution.

Default: 0

mipfocus (*integer*): Controls the focus of the MIP solver [↔](#)

Default: 0

value	meaning
0	Balance between finding good feasible solutions and proving optimality
1	Focus towards finding feasible solutions
2	Focus towards proving optimality
3	Focus on moving the best objective bound

mipgap (*real*): Relative MIP optimality gap [↔](#)

The MIP engine will terminate (with an optimal result) when the gap between the lower and upper objective bound is less than **MipGap** times the upper bound.

Range: $[0, \infty]$

Default: GAMS optcr

mipgapabs (*real*): Absolute MIP optimality gap [↔](#)

The MIP solver will terminate (with an optimal result) when the gap between the lower and upper objective bound is less than **MIPGapAbs**.

Range: $[0, \infty]$

Default: GAMS optca

mipsepcuts (*integer*): Controls MIP separation cut generation [↔](#)

See the description of the global [Cuts](#) parameter for further information.

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

mipstart (*boolean*): Use mip starting values [↔](#)

Default: 0

value	meaning
0	Do not use the values
1	Use the values

miqcpmethod (*integer*): Determines whether outer approximation is used to solve an MIQCP model. [↩](#)

Controls the method used to solve MIQCP models. Value 1 uses a linearized, outer-approximation approach, while value 0 solves continuous QCP relaxations at each node. The default setting (-1) chooses automatically.

Default: -1

value	meaning
-1	Auto
0	Linearized, outer-approximation approach
1	Continuous QCP relaxations at each node

mircuts (*integer*): Controls MIR cut generation [↩](#)

See the description of the global [Cuts](#) parameter for further information.

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

modkcuts (*integer*): Controls the generation of mod-k cuts [↩](#)

See the description of the global [Cuts](#) parameter for further information.

Default: -1

multiobjmethod (*integer*): Method used for multi-objective solves [↩](#)

When solving a continuous multi-objective model using a hierarchical approach, the model is solved once for each objective. The algorithm used to solve for the highest priority objective is controlled by the [Method](#) parameter. This parameter determines the algorithm used to solve for subsequent objectives. As with the [Method](#) parameters, values of 0 and 1 use primal and dual simplex, respectively. A value of 2 indicates that warm-start information from previous solves should be discarded, and the model should be solved from scratch (using the algorithm indicated by the [Method](#) parameter). The default setting of -1 usually chooses primal simplex.

Default: -1

multiobjpre (*integer*): Initial presolve level on multi-objective models [↩](#)

Controls the initial presolve level used for multi-objective models. Value 0 disables the initial presolve, value 1 applies presolve conservatively, and value 2 applies presolve aggressively. The default -1 value usually applies presolve conservatively. Aggressive presolve may increase the chance of the objective values being slightly different than those for other options.

Default: -1

multobj (*boolean*): Controls the hierarchical optimization of multiple objectives ↩

Default: 0

names (*boolean*): Indicator for loading names ↩

Default: 1

value	meaning
0	Do not load GAMS names into Gurobi model
1	Load GAMS names into Gurobi model

networkcuts (*integer*): Controls network cut generation ↩

See the description of the global [Cuts](#) parameter for further information.

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

nodefiledir (*string*): Nodefile directory ↩

Determines the directory into which nodes are written when node memory usage exceeds the specified NodefileStart value.

Default: .

nodefilestart (*real*): Nodefile starting indicator ↩

Controls the point at which MIP tree nodes are written to disk. Whenever node storage exceeds the specified value (in GBytes), nodes are written to disk.

Default: maxdouble

odelimit (*real*): Limits the number of MIP nodes explored ↩

Default: maxdouble

nodemethod (*integer*): Algorithm used to solve node relaxations in a MIP model ↩

Algorithm used for MIP node relaxations. Note that barrier is not an option for MIQP node relaxations.

Default: 1

value	meaning
0	Primal simplex
1	Dual simplex
2	Barrier

noelheuristic (*boolean*): No relaxation heuristic attempts to find feasible solutions without solving root relaxation ↩

Gurobi 5.6.2 introduces an experimental no relaxation heuristic that attempts to find good quality feasible solutions to MIP models without first solving the root relaxation. This can be useful in situations where the root relaxation is extremely large or difficult.

Default: 0

value	meaning
0	Do not use no relaxation heuristic
1	Try no relaxation heuristic

normadjust (*integer*): Pricing norm variants ↩

Chooses from among multiple pricing norm variants. The default value of -1 chooses automatically.

Default: -1

numericfocus (*integer*): Set the numerical focus ↩

The **NumericFocus** parameter controls the degree to which the code attempts to detect and manage numerical issues. The default setting makes an automatic choice, with a slight preference for speed. Settings 1-3 increasingly shift the focus towards being more careful in numerical computations. With higher values, the code will spend more time checking the numerical accuracy of intermediate results, and it will employ more expensive techniques in order to avoid potential numerical issues.

Default: 0

objnabstol (*string*): Allowable absolute degradation for objective ↩

This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization (**MultObj**). The syntax for this parameter is **ObjName value**.

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. If it achieves objective value z when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most **ObjNabstol**.

objnreltol (*string*): Allowable relative degradation for objective ↩

This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization (**MultObj**). The syntax for this parameter is **ObjName value**.

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. If it achieves objective value z when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most **ObjNreltol*** $|z|$.

objscale (*real*): Objective coefficients scaling ↩

Divides the model objective by the specified value to avoid numerical errors that may result from very large objective coefficients. The default value of 0 decides on the scaling automatically. A value less than zero uses the maximum coefficient to the specified power as the scaling (so `ObjScale=-0.5` would scale by the square root of the largest objective coefficient).

Range: $[-1, \infty]$

Default: 0

optimalitytol (*real*): Dual feasibility tolerance ↩

Reduced costs must all be larger than `OptimalityTol` in the improving direction in order for a model to be declared optimal.

Range: $[1\text{e-}9, 1\text{e-}2]$

Default: `1e-6`

.partition (*integer*): Variable partition value ↩

The MIP solver can perform a solution improvement heuristic using user-provided partition information. The provided partition number can be positive, which indicates that the variable should be included when the correspondingly numbered sub-MIP is solved, 0 which indicates that the variable should be included in every sub-MIP, or -1 which indicates that the variable should not be included in any sub-MIP. Variables that are not included in the sub-MIP are fixed to their values in the current incumbent solution.

To give an example, imagine you are solving a model with 400 variables and you set the partition attribute to -1 for variables 0-99, 0 for variables 100-199, 1 for variables 200-299, and 2 for variables 300-399. The heuristic would solve two sub-MIP models: sub-MIP 1 would fix variables 0-99 and 300-399 to their values in the incumbent and solve for the rest, while sub-MIP 2 would fix variables 0-99 and 200-299.

The parameter `PartitionPlace` controls the use of the heuristic. The partition numbers are specified through the option `.partition`. The syntax for [dot options](#) is explained in the Introduction chapter of the Solver Manual.

Default: 0

partitionplace (*integer*): Controls where the partition heuristic runs ↩

This option works in combination with the `Partition` number for variables. Setting this option and providing some partitions enables the partitioning heuristic, which uses large-neighborhood search to try to improve the current incumbent solution.

This parameter determines where that heuristic runs. Options are:

- Before the root relaxation is solved (16)
 - At the start of the root cut loop (8)
 - At the end of the root cut loop (4)
 - At the nodes of the branch-and-cut search (2)
 - When the branch-and-cut search terminates (1)
-

The parameter value is a bit vector, where each bit turns the heuristic on or off at that place. The numerical values next to the options listed above indicate which bit controls the corresponding option. Thus, for example, to enable the heuristic at the beginning and end of the root cut loop (and nowhere else), you would set the 8 bit and the 4 bit to 1, which would correspond to a parameter value of 12.

The recommended value is 15 which indicates that every option except the first one listed above is enabled.

Default: 0

perturbvalue (*real*): Magnitude of simplex perturbation when required ↔

Range: [0, 0.01]

Default: 0.0002

poolgap (*real*): Maximum gap for stored solutions ↔

Determines how large a gap to tolerate in stored solutions. When this parameter is set to a non-default value, solutions whose objective values exceed that of the best known solution by more than the specified (relative) gap are discarded. For example, if the MIP solver has found a solution at objective 100, then a setting of `PoolGap=0.2` would discard solutions with objective worse than 120 (assuming a minimization objective).

Default: `maxdouble`

poolsearchmode (*integer*): Selects different modes for exploring the MIP search tree ↔

With the default setting (`PoolSearchMode=0`), the MIP solver tries to find an optimal solution to the model. It keeps other solutions found along the way, but those are incidental. By setting this parameter to a non-default value, the MIP search will continue after the optimal solution has been found in order to find additional, high-quality solutions. With a setting of 2, it will find the *n* best solutions, where *n* is determined by the value of the [PoolSolutions](#) parameter. With a setting of 1, it will try to find additional solutions, but with no guarantees about the quality of those solutions. The cost of the solve will increase with increasing values of this parameter.

Once optimization is complete, the *PoolObjBound* attribute (printed to the log) can be used to evaluate the quality of the solutions that were found. For example, a value of `PoolObjBound=100` indicates that there are no other solutions with objective better 100, and thus that any known solutions with objective better than 100 are better than any as-yet undiscovered solutions.

Default: 0

poolsolutions (*integer*): Number of MIP solutions to store ↔

Determines how many MIP solutions are stored. For the default value of [PoolSearchMode](#), these are just the solutions that are found along the way in the process of exploring the MIP search tree. For other values of [PoolSearchMode](#), this parameter sets a target for how many solutions to find, so larger values will impact performance.

Default: 10

precrush (*integer*): Presolve constraint option ↔

Allows presolve to translate constraints on the original model to equivalent constraints on the presolved model. This parameter is turned on when you use BCH with Gurobi.

Default: 0

predeprow (*integer*): Controls the presolve dependent row reduction [↔](#)

Controls the presolve dependent row reduction, which eliminates linearly dependent constraints from the constraint matrix. The default setting (-1) applies the reduction to continuous models but not to MIP models. Setting 0 turns the reduction off for all models. Setting 1 turns it on for all models.

Default: -1

predual (*integer*): Controls whether presolve forms the dual of a continuous model [↔](#)

Depending on the structure of the model, solving the dual can reduce overall solution time. The default setting uses a heuristic to decide. Setting 0 forbids presolve from forming the dual, while setting 1 forces it to take the dual. Setting 2 employs a more expensive heuristic that forms both the presolved primal and dual models (on two threads), and heuristically chooses one of them.

Default: -1

premiqcpform (*integer*): Determines the format of the presolved version of an MIQCP model [↔](#)

Option 0 leaves the model in MIQCP form, so the branch-and-cut algorithm will operate on a model with arbitrary quadratic constraints. Option 1 always transforms the model into MISOCP form; quadratic constraints are transformed into second-order cone constraints. Option 2 always transforms the model into disaggregated MISOCP form; quadratic constraints are transformed into rotated cone constraints, where each rotated cone contains two terms and involves only three variables.

Default: -1

value	meaning
-1	Auto
0	Always leaves the model in MIQCP form
1	Always transforms the model into MISOCP form
2	Always transforms the model into disaggregated MISOCP form

premiqpmethod (*integer*): Transformation presolve performs on MIQP models [↔](#)

Chooses the transformation presolve performs on MIQP models.

Default: -1

value	meaning
-1	Auto
0	Always leaves the model as an MIQP
1	Attempts to transform the model into an MILP

prepasses (*integer*): Controls the number of passes performed by presolve [↔](#)

Limits the number of passes performed by presolve. The default setting (-1) chooses the number of passes automatically.

Default: -1

preqlinearize (*integer*): Controls linearization of Q matrices in the quadratic constraints or a quadratic objective ↩

Options 1 and 2 attempt to linearize quadratic constraints or a quadratic objective, potentially transforming an MIQP or MIQCP model into an MILP. Option 1 focuses on getting a strong LP relaxation. Option 2 aims for a compact relaxation. Option 0 always leaves Q matrices unmodified. The default setting (-1) chooses automatically.

Default: -1

value	meaning
-1	Auto
0	Linearization off
1	Force Linearization and get strong LP relaxation
2	Force Linearization and get compact relaxation

presolve (*integer*): Controls the presolve level ↩

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

presos1bigm (*real*): Threshold for SOS1-to-binary reformulation ↩

Controls the automatic reformulation of SOS1 constraints into binary form. SOS1 constraints are often handled more efficiently using a binary representation. The reformulation often requires big-M values to be introduced as coefficients. This parameter specifies the largest big-M that can be introduced by presolve when performing this reformulation. Larger values increase the chances that an SOS1 constraint will be reformulated, but very large values (e.g., 1e8) can lead to numerical issues.

The default value of -1 chooses a threshold automatically. You should set the parameter to 0 to shut off SOS1 reformulation entirely, or a large value to force reformulation.

Range: $[-1, \infty]$

Default: -1

presos2bigm (*real*): Threshold for SOS2-to-binary reformulation ↩

Controls the automatic reformulation of SOS2 constraints into binary form. SOS2 constraints are often handled more efficiently using a binary representation. The reformulation often requires big-M values to be introduced as coefficients. This parameter specifies the largest big-M that can be introduced by presolve when performing this reformulation. Larger values

increase the chances that an SOS2 constraint will be reformulated, but very large values (e.g., 1e8) can lead to numerical issues.

The default value of 0 disables the reformulation. You can set the parameter to -1 to choose an automatic approach, or a large value to force reformulation.

Range: $[-1, \infty]$

Default: 0

presparsify (*boolean*): Enables the presolve sparsify reduction for MIP models [↔](#)

This reduction can sometimes significantly reduce the number of nonzero values in the presolved model.

Default: 0

value	meaning
0	Disable the presolve sparsify reduction
1	Enable the presolve sparsify reduction

prntoptions (*boolean*): List values of all options to GAMS listing file [↔](#)

Default: 0

value	meaning
0	Do not list option values to GAMS listing file
1	List option values to GAMS listing file

.prior (*real*): Branching priorities [↔](#)

GAMS allows to specify priorities for discrete variables only. Gurobi can detect that continuous variables are implied discrete variables and can utilize priorities. Such priorities can be specified through a GAMS/Gurobi solver option file. The syntax for [dot options](#) is explained in the Introduction chapter of the Solver Manual. The priorities are only passed on to Gurobi if the model attribute `priorOpt` is turned on.

Default: 1

psdtol (*real*): limit on the amount of diagonal perturbation [↔](#)

Positive semi-definite tolerance (for QP/MIQP). Sets a limit on the amount of diagonal perturbation that the optimizer is allowed to automatically perform on the Q matrix in order to correct minor PSD violations. If a larger perturbation is required, the optimizer will terminate stating the problem is not PSD.

Range: $[0, \infty]$

Default: 1e-6

pumppasses (*integer*): Number of passes of the feasibility pump heuristic [↔](#)

Note that this heuristic is only applied at the end of the MIP root, and only when no other root heuristic found a feasible solution.

Default: 0

qcpdual (*boolean*): Determines whether dual variable values are computed for QCP models [↔](#)

Determines whether dual variable values are computed for QCP models. Computing them can add significant time to the optimization, so you should turn this parameter to 0 if you do not need them.

Default: 1

value	meaning
0	Do not compute dual for QCP problem
1	Compute dual for QCP problem

quad (*integer*): Quad precision computation in simplex [↔](#)

Enables or disables quad precision computation in simplex. The -1 default setting allows the algorithm to decide.

Default: -1

readparams (*string*): Read Gurobi parameter file [↔](#)

rerun (*integer*): Resolve without presolve in case of unbounded or infeasible [↔](#)

In case Gurobi reports *Model was proven to be either infeasible or unbounded*, this option decides about a resolve without presolve which will determine the exact model status. If the option is set to *auto*, which is the default, and the model fits into demo limits, the problems is resolved.

Default: 0

value	meaning
-1	No
0	Auto
1	Yes

rins (*integer*): Frequency of the RINS heuristic [↔](#)

Default value (-1) chooses automatically. A value of 0 shuts off RINS. A positive value n applies RINS at every n -th node of the MIP search tree.

Default: -1

scaleflag (*integer*): Enables or disables model scaling [↔](#)

Controls model scaling. By default, the rows and columns of the model are scaled in order to improve the numerical properties of the constraint matrix. The scaling is removed before the final solution is returned. Scaling typically reduces solution times, but it may lead to larger constraint violations in the original, unscaled model. Turning off scaling `ScaleFlag=0` can sometimes produce smaller constraint violations. Choosing a more aggressive scaling option `ScaleFlag=2` can sometimes improve performance for particularly numerically difficult models.

freemsgmodel In order to provide the maximum amount of memory to the solver this option dumps the internal representation of the model instance temporarily to disk and frees memory. This option only works with `SolveLink=0` and only for models without quadratic constraints.

Default: 1

seed (*integer*): Random number seed ↔

Modifies the random number seed. This acts as a small perturbation to the solver, and typically leads to different solution paths.

Default: 0

sensitivity (*boolean*): Provide sensitivity information ↔

Default: 0

value	meaning
0	Do not provide sensitivity information
1	Provide sensitivity information

sifting (*integer*): Sifting within dual simplex ↔

Enables or disables sifting within dual simplex. Sifting is often useful for LP models where the number of variables is many times larger than the number of constraints. With a *Moderate* setting, sifting will be applied to LP models and to the root node for MIP models. With an *Aggressive* setting, sifting will be also applied to the nodes of a MIP. Note that this parameter has no effect if you aren't using dual simplex. Note also that sifting will be skipped in cases where it is obviously a worse choice, even when sifting has been selected.

Default: -1

value	meaning
-1	Auto
0	Off
1	Moderate
2	Agressive

siftmethod (*integer*): LP method used to solve sifting sub-problems ↔

Note that this parameter only has an effect when you are using dual simplex and sifting has been selected (either by the automatic method, or through the [Sifting](#) parameter).

Default: -1

value	meaning
-1	Auto
0	Primal Simplex
1	Dual Simplex
2	Barrier

simplexpricing (*integer*): Determines variable pricing strategy ↔

Default: -1

value	meaning
-1	Auto
0	Partial Pricing

value	meaning
1	Steepest Edge
2	Devex
3	Quick-Start Steepest Edge

solnpool (*string*): Controls export of alternate MIP solutions ↩

The GDX file specified by this option will contain a set call **index** that contains the names of GDX files with the individual solutions. For details see example model **dumpsol** in the GAMS Test Library. The option [PoolSolutions](#), [PoolSearchModel](#), and [PoolGap](#) control the search for alternative solutions. Please also refer to the section [Solution Pool](#).

threads Default number of parallel threads allowed for any solution method. Non-positive values are interpreted as the number of cores to leave free so setting threads to 0 uses all available cores while setting threads to -1 leaves one core free for other tasks.

solutionlimit (*integer*): Limits the number of feasible solutions found ↩

Default: **maxint**

solvefixed (*boolean*): Indicator for solving the fixed problem for a MIP to get a dual solution ↩

Default: 1

value	meaning
0	Do not solve the fixed problem
1	Solve the fixed problem

startodelimit (*integer*): Limit MIP start sub-MIP nodes ↩

This parameter limits the number of branch-and-bound nodes explored when completing a partial MIP start. The default value of -1 uses the value of the [subMIPNodes](#) parameter. A value of -2 shuts off MIP start processing entirely. Non-negative values are node limits.

Default: -1

strongcgcuts (*integer*): Strong-CG cut generation ↩

Controls Strong Chvátal-Gomory (Strong-CG) cut generation. Use 0 to disable these cuts, 1 for moderate cut generation, or 2 for aggressive cut generation. The default -1 value chooses automatically. Overrides the [Cuts](#) parameter.

Default: -1

submipcuts (*integer*): Controls the generation of sub-MIP cutting planes ↩

See the description of the global [Cuts](#) parameter for further information.

Default: -1

submipnodes (*integer*): Limits the number of nodes explored by the heuristics ↩

Limits the number of nodes explored by the heuristics, like RINS. Exploring more nodes can produce better solutions, but it generally takes longer.

Default: 500

symmetry (*integer*): Controls MIP symmetry detection ↩

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

threads (*integer*): Controls the number of threads to apply to parallel MIP or Barrier ↔

Default: GAMS threads

timelimit (*real*): Limits the total time expended in seconds ↔

Default: GAMS reslim

tunecriterion (*integer*): Tuning criterion ↔

Modifies the tuning criterion for the tuning tool. The primary tuning criterion is always to minimize the runtime required to find a proven optimal solution. However, for MIP models that don't solve to optimality within the specified time limit, a secondary criterion is needed. Set this parameter to 1 to use the optimality gap as the secondary criterion. Choose a value of 2 to use the objective of the best feasible solution found. Choose a value of 3 to use the best objective bound. Choose 0 to ignore the secondary criterion and focus entirely on minimizing the time to find a proven optimal solution. The default value of -1 chooses automatically.

Default: -1

tunejobs (*integer*): Distributed tuning job count ↔

Enables distributed parallel tuning, which can significantly increase the performance of the tuning tool. A value of n causes the tuning tool to distribute tuning work among n parallel jobs. These jobs are distributed among a set of workers. Use the [WorkerPool](#) parameter to provide a list of available workers.

Note that distributed tuning is most effective when the workers have similar performance. Distributed tuning doesn't attempt to normalize performance by worker, so it can incorrectly attribute a boost in performance to a parameter change when the associated setting is tried on a worker that is significantly faster than the others.

Default: 0

tuneoutput (*integer*): Tuning output level ↔

Default: 2

value	meaning
0	No output
1	Summary output only when a new best parameter set is found
2	Summary output for each parameter set that is tried
3	Summary output, plus detailed solver output, for each parameter set tried

tuneresults (*integer*): Number of improved parameter sets returned ↔

The tuning tool often finds multiple parameter sets that produce better results than the baseline settings. This parameter controls how many of these sets should be retained when tuning is complete.

Default: 1

tunetimelimit (*real*): Time limit for tuning ↔

Limits total tuning runtime (in seconds). The default setting (-1) chooses a time limit automatically.

Default: -1

tunetrials (*integer*): Perform multiple runs on each parameter set to limit the effect of random noise ↔

Performance on a MIP model can sometimes experience significant variations due to random effects. As a result, the tuning tool may return parameter sets that improve on the baseline only due to randomness. This parameter allows you to perform multiple solves for each parameter set, using different Seed values for each, in order to reduce the influence of randomness on the results.

Note: Only affects mixed integer programming (MIP) models

Default: 2

tuning (*string*): Parameter Tuning ↔

Invokes the Gurobi parameter tuning tool. The mandatory value following the keyword specifies a GAMS/Gurobi option file. All options found in this option file will be used but not modified during the tuning. A sequence of file names specifying existing problem files may follow the option file name. The files can be in MPS, REW, LP, RLP, and ILP format created by the [WriteProb](#) option. Gurobi will tune the parameters either for the problem provided by GAMS (no additional problem files specified) or for the suite of problems listed after the GAMS/Gurobi option file name without considering the problem provided by GAMS. The result of such a run is the updated GAMS/Gurobi option file with a tuned set of parameters. In case the option [TuneResults](#) is larger than 1, GAMS/Gurobi will create a sequence of GAMS/Gurobi option files. The solver and model status returned to GAMS will be **NORMAL COMPLETION** and **NO SOLUTION**. Tuning is incompatible with advanced features like [FeasOpt](#) of GAMS/Gurobi.

usebasis (*integer*): Use basis from GAMS ↔

If **UseBasis** is not specified, GAMS (via option **BRatio**) decides if the starting basis or a primal/dual solution is given to Gurobi. If **UseBasis** is explicitly set in an option file then the basis or a primal/dual solution is passed to Gurobi independent of the GAMS option **BRatio**. Please note, if Gurobi uses a starting basis presolve will be skipped.

Default: GAMS **bratio**

value	meaning
0	No basis
1	Supply basis if basis is full otherwise provide primal dual solution
2	Supply basis iff basis is full
3	Supply primal dual solution

varbranch (*integer*): Controls the branch variable selection strategy ↔

Default: -1

value	meaning
-1	Auto
0	Pseudo Reduced Cost Branching
1	Pseudo Shadow Price Branching
2	Maximum Infeasibility Branching
3	Strong Branching

varhint (*boolean*): Guide heuristics and branching through variable hints ↩

If you know that a variable is likely to take a particular value in high quality solutions of a MIP model, you can provide this information as a hint. If **VarHint** option is active, GAMS/Gurobi will pass variable levels rounded to the nearest integer as hints to Gurobi if their level is within **TryInt** of an integer. The closer the level is to the rounded integer the higher your level of confidence in this hint. Internally this is recalculated into a Gurobi variable hint priority: $\left\lceil \frac{1}{\max(10^{-6}, |x.l - [x.l]|)} \right\rceil$

The Gurobi MIP solver will use these variable hints in a number of different ways. Hints will affect the heuristics that Gurobi uses to find feasible solutions, and the branching decisions that Gurobi makes to explore the MIP search tree. In general, high quality hints should produce high quality MIP solutions faster. In contrast, low quality hints will lead to some wasted effort, but shouldn't lead to dramatic performance degradations.

Variables hints and [MIP starts](#) are similar in concept, but they behave in very different ways. If you specify a MIP start, the Gurobi MIP solver will try to build a single feasible solution from the provided set of variable values. If you know a solution, you should use a MIP start to provide it to the solver. In contrast, variable hints provide guidance to the MIP solver that affects the entire solution process. If you have a general sense of the likely values for variables, you should provide them through variable hints.

Default: 0

workerpassword (*string*): Compute server password Pool of compute servers to use for distributed algorithms ↩

When using a distributed algorithm (the distributed concurrent MIP solver or distributed tuning), this parameter allows you to specify the password for the workers listed in the [WorkerPool](#) parameter.

workerpool (*string*): Pool of compute servers to use for distributed algorithms ↩

When using a distributed algorithm (distributed MIP, distributed concurrent, or distributed tuning), this parameter allows you to specify a Remote Services cluster that will provide distributed workers. You should also specify the access password for that cluster, if there is one, in the [WorkerPassword](#) parameter.

You can provide a comma-separated list of machines for added robustness. If the first node in the list is unavailable, the client will attempt to contact the second node, etc.

To give an example, if you have a Remote Services cluster that uses port 61000 on a pair of machines named server1 and server2, you could set WorkerPool to **server1:61000 server1:61000,server2:61000**.

workerport (*integer*): Non-default port number for distributed workers ↩

When using a distributed algorithm (distributed MIP, distributed concurrent, or distributed tuning), this parameter allows you to specify a non-default port number for the distributed worker machines. All workers should use the same port number. The list of distributed workers should be specified via the [WorkerPool](#) parameter.

Default: -1

writeparams (*string*): Write Gurobi parameter file [↔](#)

writeprob (*string*): Save the problem instance [↔](#)

zerohalfcuts (*integer*): Controls zero-half cut generation [↔](#)

See the description of the global [Cuts](#) parameter for further information.

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

zeroobjnodes (*integer*): Number of nodes to explore in the zero objective heuristic [↔](#)

Note that this heuristic is only applied at the end of the MIP root, and only when no other root heuristic finds a feasible solution.

Default: 0

5.23 Gather-Update-Solve-Scatter (GUSS)

5.23.1 Introduction

The purpose of this chapter is to detail an extension of the GAMS modeling system that allows collections of models (parameterized exogenously by a set of samples or indices) to be described, instantiated, and solved efficiently.

As a specific example, we consider the parametric optimization problem $\mathcal{P}(s)$ defined by:

$$\min_{x \in X(s)} f(x; s) \text{ s.t. } g(x; s) \leq 0 \quad (5.11)$$

where $s \in S = \{1, \dots, K\}$. Note that each scenario s represents a different problem for which the optimization variable is x . The form of the constraint set as given above is simply for concreteness; equality constraints and range and bound constraints are trivial extensions of the above framework. Clearly the problems $\mathcal{P}(s)$ are interlinked. We intend to show how such problems can be easily specified within GAMS, and detail one type of algorithmic extension that can exploit the nature of the linkage. Other extensions of GAMS allow solves to be executed in parallel or by using grid computing resources. Note that in our description we will use the terms indexed, parameterized, and scenario somewhat interchangeably. An extended version of this chapter containing several examples is available as a paper at <http://www.gams.com/modlib/adddocs/gusspaper.pdf>.

5.23.2 Design Methodology

One of the most important functions of GAMS is to build a model instance from the collection of equations (i.e. an optimization model defined by the GAMS keyword `MODEL`) and corresponding data (consisting of the content of GAMS (sub)sets and parameters). Such a model instance is constructed or generated when the GAMS execution system executes a `SOLVE` statement. The generated model instance is passed to a solver which searches for a solution of this model instance and returns status information, statistics, and a (primal and dual) solution of the model instance. After the solver terminates, GAMS brings the solution back into the GAMS database, i.e. it updates the level (.L) and marginal (.M) fields of variable and equation symbols used in the model instance. Hence, the `SOLVE` statement can be interpreted as a complex operator against the GAMS database. The model instance generated by a `SOLVE` statement only lives during the execution of this one statement, and hence has no representation within the GAMS language. Moreover, its structure does fit the relational data model of GAMS. A model instance consists of vectors of bounds and right hand sides, a sparse matrix representation of the Jacobian, a representation of the non-linear expressions that allow the efficient calculation of gradient vectors and Hessian matrices, and so on.

This chapter is concerned with solving collections of models that have similar structure but modified data. As an example, consider a linear program of the form:

$$\min c^T x \text{ s.t. } Ax \geq b, \ell \leq x \leq u.$$

The data in this problem is (A, b, c, ℓ, u) . Omitting some details, the following code could be used within GAMS to solve a collection of such linear programs in which each member of the collection has a different A matrix and lower bound ℓ :

```
Set      i / ... /, j / ... /;
Parameter A(i,j), b(i);
Variable x(j), z, ...;
Equation e(i), ...;
e(i).. sum(j, A(i,j)*x(j)) =g= b(i);
...
model mymodel /all/;

Set s / s1*s10 /
Parameter
    A_s(s,i,j) 'Scenario data'
    xlo_s(s,j) 'Scenario lower bound for variable x'
    xl_s(s,j)  'Scenario solution for x.l'
    em_s(s,i)  'Scenario solution for e.m';
Loop(s,
    A(i,j) = A_s(s,i,j);
    x.lo(j) = xlo_s(s,j);
    solve mymodel min z using lp;
    xl_s(s,j) = x.l(j);
    em_s(s,i) = e.m(i);
);
```

Summarizing, we solve one particular model (`mymodel`) in a loop over `s` with an unchanged model rim (i.e. the same individual variables and equations) but with different model data and different bounds for the variables. The change in model data for a subsequent solve statement does not depend on the previous model solutions in the loop.

The purpose of this new Gather-Update-Solve-Scatter (GUSS) manager is to provide syntax at the GAMS modeling level that makes an instance of a problem that provides limited access to treat that instance as an object, and allows the modeler to update portions of it iteratively. Specifically, we provide syntax that gives a list of data changes to an instance, and allows these changes to be applied sequentially to

the instance (which is then solved without returning to GAMS). Thus, we can simulate a limited set of actions to be applied to the model instance object and retrieve portions of the solution of these changed instances back in the modeling environment. Such changes can be done to any model type in GAMS, including nonlinear problems and mixed integer models. However, the only changes we allow are to named parameters appearing in the equations and lower and upper bounds used in the model definition.

Thus, in the above example GUSS allows us to replace lines 15-21 by

```
Set dict / s.    scenario. ''
      A.    param.    A_s
      x.    lower.    xlo_s
      x.    level.    xl_s
      e.    marginal. em_s  /;
solve mymodel min z using lp scenario dict;
```

The three dimensional **set dict** (you can freely choose the name of this symbol) contains mapping information between symbols in the model (in the first position) and symbols that supply required update data or store solution information (in the third position), and the type of update/storing (in the second position). An exception to this rule is the tuple with label **scenario** in the second position. This tuple determines the symbol (in the first position) that is used as the scenario index. This scenario symbol can be a multidimensional set. A tuple in this set represents a single scenario. The remaining tuples in the **set dict** can be grouped into input and output tuples. Input tuples determine the modifications of the model instance prior to solving, while output tuples determine which part of the solution gets saved away. The following keywords can be used in the second position of the set **dict**:

Type	Keywords	Description
Input:	param	Supplies scenario data for a parameter used in the model
	lower	Supplies scenario lower bounds for a variable
	upper	Supplies scenario upper bounds for a variable
	fixed	Supplies scenario fixed bounds for a variable
Output:	level	Stores the levels of a scenario solution of variable or equation
	marginal	Stores the marginals of a scenario solution of variable or equation

Sets in the model cannot be updated. GUSS works as follows: GAMS generates the model instance for the original data. As with regular **SOLVE** statements, all the model data (e.g. parameter **A**) needs to be defined at this time. The model instance with the original data is also called the *base case*. The solution of the base case is reported back to GAMS in the regular way and is accessible via the regular **.L** and **.M** fields after the **SOLVE** statement. After solving the base case, the update data for the first scenario is applied to the model. The tuples with **lower**, **upper**, **fixed** update the bounds of the variables, whereas the tuples with **param** update the parameters in the model.

The scenario index **s** needs to be the first index in the parameters mapped in the **set dict**. The update of the model parameters goes far beyond updating the coefficients of the constraint matrix/objective function or the right hand side of an equation, as one can do with some other systems. GAMS stores all the necessary expressions of the constraints with the model instance, so the change in the constraint matrix coefficient is the result of an expression evaluation. For example, consider a term in the calculation of the cost for shipping a variable amount of goods $x(i,j)$ between cities i and j . The expression for shipping cost is $d(i,j)*f*x(i,j)$, i.e. the distance between the cities times a freight rate f times the variable amount of goods. In order to find out the sensitivity of the solution with respect to the freight rate f , one can solve the same model with different values for f . In a matrix representation of the model one would need to calculate the coefficient of $x(i,j)$ which is $d(i,j)*f$, but with GUSS it is sufficient to supply different values for f that potentially result in many modified coefficients on the matrix level. GUSS evaluates the shipping cost term and communicates the resulting matrix coefficient to the solver reliably behind the scenes.

After the variable bound and the model parameter updates have been applied and the resulting updates to the model instance data structures (e.g. constraint matrix) has been determined, the modified model instance is passed to the solver. Some solvers (e.g. Cplex, Gurobi, SoPlex, and Xpress) allow modifying a model instance. In these cases GUSS only communicates the changes from the previous model instance to the solver. This reduces the amount of data communicated to the solver and also, in the case of an LP model, allows the solver to restart from an advanced basis and its factorization. In the case of an NLP model, this provides initial values. After the solver determines the solution of a model instance, GUSS stores the part of the solution requested by the output tuples of `dict` to some GAMS parameters and continues with the next scenario. GUSS emphasizes on speed and only works with solver that allow to communicate the model instance through memory. Hence, the following solvers cannot be used as subsolvers of GUSS: ALPHAECF, AMPL, BARON, BDMLP, BENCH, CONVERT, DECISC, DECISM, DICOPT, EXAMINER, GAMSCHK, JAMS, KESTREL, LINGO, LOGMIP, LS, MILES, MPECDUMP, MPSGE, MSNLP, NLPEC, PATHNLP, SBB, and XA.

5.23.3 GUSS Options

The execution of GUSS can be parameterized using some options. Options are not passed through a solver option file but via another tuple in the `dict` set. The keyword in the second position of this tuple is `opt`. A one dimensional parameter is expected in the first position (or the label `''`). This parameter may contain some of the following labels with values:

Options	Description
<code>OptfileInit:</code>	Option file number for the first solve (default from GAMS OptFile setting)
<code>Optfile:</code>	Option file number for subsequent solves (default 0)
<code>LogOption:</code>	Determines amount of log output: 0 - Moderate log (default) 1 - Minimal log 2 - Detailed log
<code>NoHotStart:</code>	Disable hot start capability in solver that supports hot starts (default 0)
<code>NoMatchLimit:</code>	Limit of unmatched scenario records (default 0)
<code>RestartType::</code>	Determines restart point for the scenarios 0 - Restart from last solution (default) 1 - Restart from solution of base case 2 - Restart from input point
<code>SkipBaseCase:</code>	Switch for solving the base case (0 solves the base case)
<code>ReportLastScen:</code>	Switch for reporting the solution of the last scenario rather than solution of the base case (default 0)
<code>SolveEmpty:</code>	Limit of solved empty scenarios, afterwards scenarios will be skipped (default 0)
<code>UpdateType:</code>	Scenario update mechanism: 0 - Set everything to zero and apply changes (default) 1 - Reestablish base case and apply changes 2 - Build on top of last scenario and apply changes

For the example model above the `UpdateType` setting would mean:

```
UpdateType=0: loop(s, A(i,j) = A_s(s,i,j))
UpdateType=1: loop(s, A(i,j) = A_base(i,j);
               A(i,j) $= A_s(s,i,j))
UpdateType=2: loop(s, A(i,j) $= A_s(s,i,j))
```

The option `SkipBaseCase=1` allows the user to skip the base case. This means only the scenarios are solved and there is no solution reported back to GAMS in the traditional way. The third position in the

opt-tuple can contain a parameter for storing the scenario solution attribute information, e.g. model and solve status, or needs to have the label ''. The labels to store solution status information must be known to GAMS, so one needs to declare a set with such labels. A convenient way to enter these attributes is via `System.GUSSModelAttributes`:

```
Set ma 'GUSS Model Attributes' / System.GUSSModelAttributes /; display ma;
```

```
-----      1 SET ma  GUSS Model Attributes

ModelStat,    SolveStat,    NumInfes ,    SumInfes ,    IterUsd
ResUsd      ,    ObjVal    ,    NodUsd   ,    ObjEst   ,    DomUsd
RObj        ,    MaxInfes ,    MeanInfes
```

The following example shows how to use some of the GUSS options and the use of a parameter to store some solution status information:

```
Set h solution headers / System.GUSSModelAttributes /;
Parameter
  o / SkipBaseCase 1, UpdateType 1, Optfile 1 /
  r_s(s,h) Solution status report;
Set dict / s.    scenario. ''
           o.    opt.      r_s
           a.    param.    a_s
           x.    lower.    xlo_s
           x.    level.    xl_s
           e.    marginal. em_s /;
solve mymodel min z using lp scenario dict;
```

Please note that the domain set of the solution status report attributes (here `h`) must only contain model attributes known to GUSS. If this domain (unless the domain in `*`) contains a label unknown to GUSS, a compilation error is triggered.

5.23.4 Implementation Details

This section describes some technical details that may provide useful insight in case of unexpected behavior.

Because GUSS changes all model parameters mentioned in the `dict` set to variables, a linear model can produce some non-linear instructions (e.g. `d(i,j)*f*x(i,j)` becomes a non-linear expression since `f` becomes a variable in the model instance given to GUSS). This also explains why some models compile without complaint, but if the model is used in the context of GUSS, the compile time check of the model will fail because a parameter that is turned into a variable can no longer be used in that way. For example, suppose the model contains a constraint `e(i).. sum(j$A(i,j), ...)`. If `A(i,j)` is a parameter in the regular model, the compiler will not complain, but if `A` becomes a parameter that shows up in the first position of a `param` tuple in the `dict` set, the GAMS compiler will turn `A` into a variable and complain that an endogenous variable cannot be used in a `$`-condition.

The sparsity pattern of a model can be greatly affected by GUSS. In a regular model instance GAMS will only generate and pass on non-zero matrix elements of a constraint `e(i).. sum(j, A(i,j)*x(j)) ...`, so the sparsity of `A` determines the sparsity of the generated model instance. GUSS allows to use this constraint with different values for `A` hence GUSS cannot exclude any of the pairs `(i,j)` and generate a dense matrix. The user can enforce some sparsity by explicitly restricting the `(i,j)` pairs: `e(i).. sum(ij(i,j), A(i,j)*x(j)) ...`

Attention

While GUSS is available for many model types quadratic models require special attention. Linear solvers that have been extended to cover (convex) quadratic models, e.g. Cplex, Gurobi, Mosek, Xpress, do not work properly if the modifying parameter affects the left hand side of linear equations or any modifications of quadratic equations. Bound updates as well as changes of the right hand side of linear constraints are okay (see the example of the quadratic support vector machine below). Unfortunately, detecting if a quadratic model is okay or not for a given solver is at the moment difficult to detect, so use caution with quadratic models in combination with such (linear) solvers.

The actual change of the GAMS language required for the implementation of GUSS is minimal. The only true change is the extension of the `SOLVE` statement with the term `SCENARIO dict`. Existing language elements have been used to store symbol mapping information, options, and model result statistics. Some parts of the GUSS presentation look somewhat unnatural, e.g. since `dict` is a three dimensional `set` the specification the scenario `set` using keyword `scenario` requires a third dummy label `''`. However, this approach gives maximum flexibility for future extension, allows reliable consistency checks at compile and execution time, and allows the user to delay the commitment for significant and permanent syntax changes of a developing method to handle model instances at a GAMS language level.

5.23.5 Applications

5.23.5.1 Cross Validation in GAMS via GUSS

Cross validation is a statistical/machine learning technique that aims to evaluate the generalizability of a classifier (or other decision) process. It does this by setting aside a portion of the data for testing, and uses the remaining data entries to produce the classifier. The testing data is subsequently used to evaluate how well the classifier works. Cross validation performs this whole process a number of times in order to estimate the true power of the classifier.

Ten-fold cross validation is a special case, where the original data is split into ten pieces, and cross validation is performed using each of these ten pieces as the testing set. Thus, the training process is performed ten times, each of which uses the data obtained by deleting the testing set from the whole dataset. We show below how to carry this out using the Gather-Update-Solve-Scatter (GUSS) facility in GAMS.

A paper with the title "GUSS: Solving Collections of Data Related Models within GAMS" that contains two additional application examples for GUSS is available [here](#).

5.23.5.1.1 GUSS formulation in GAMS The following example compares the two formulations for a feature-selection model under cross-validation using data files `a_data.inc` and `b_data.inc`. The actual source code for both of these GAMS formulations is available [here](#).

Original GAMS formulation (without the GAMS/DEA interface):

```

  rep(p,'objval') = train.objval;
);
display rep;

```

Options file for the original formulation: xpress.opt

```
loadmipsol=1
```

The `batinclude` file `gentestset.inc` . gives instructions for generating the testing sets. It produces `a.test` and `b.test` that detail which equations are left out on solve `p`.

The actual model is set up to include all the data points in the equations `a_def` and `b_def`. To delete the equations that correspond to the test set, we introduce nonnegative slack variables into all the equations. We then set the upper bounds of the slack variables to zero in equations corresponding to the training set, and to infinity in equations corresponding to the testing set. At the same time we fix the error measures `a_err` and `b_err` belonging to the testing set by setting their upper bounds to zero. Thus the testing set equations are always satisfiable by choice of the slack variables alone - essentially they are discarded from the model as required. An alternative formulation could "include" the data equations that you need in each scenario, but the update from one scenario to the next in the defining data is much larger.

Cross validation formulated using GUSS: This model essentially mimics what the standard model does, but the implementation of the solver loop behind the scenes is much more efficient, and the consequences are that are clear to see if you execute both model runs. The changes are in the last 40 lines of the GAMS code.

```

```

Firstly, parameters `aupper`, `bupper`, `afree` and `bfree` are used to set the bounds on the error and slack variables in the testing set equations respectively. The setting of the upper bounds are governed by the syntax shown in the controlling set `dict`. Furthermore, the output of the classifier (`w, gamma`) for each fold of the cross validation uses the `dict` set to place results into the parameters `wval` and `gval` respectively. Finally, the GUSS options are used to guarantee that the subsequent solves are instructed to process solver options (`Optfile 1`) which instruct the solver to use the previous solution to start the branch-and-cut process (`loadmipsol=1`).

The complete data and model files for this example are found in ([galaxy zip archive](#)). The data and model for a second instance based on the Wisconsin Diagnostic Breast Cancer Database is downloadable as ([wdbc zip archive](#)).

5.23.5.1.2 Quadratic Programs GUSS is not limited to linear programs, but can be used more generally. Simple (indexed) quadratic models can be solved using GUSS. The following example illustrates the use of GUSS for quadratic programs. In this example, a support vector machine is used to determine a linear classifier that separates data into two categories. We use the following model:

$$\begin{aligned}
 &\text{Min}_{w,g,z} && (1/2)\|w\|^2 + Ce^T z \\
 &\text{subject to} && D(Aw - g) + z \geq 1 \\
 &&& z \geq 0
 \end{aligned} \tag{5.12}$$

Here, A is a matrix containing the training data (patients by features) and D is a diagonal matrix with values $+1$ or -1 (each denoting one of the two classes). C is a parameter weighting the importance of

maximizing the margin between the classes ($2/\|w\|_2$) versus minimizing the misclassification error (z). The solution w and g are used to define a separating hyperplane $\{x|w^T x = g\}$ to classify (unseen) data points.

As given, the standard linear support vector machine is not a slice model per se. It becomes a slice model under cross-validation training, where it is solved multiple times on different pieces of data. In this case, only the data A and D vary between solves, appropriately fitting the definition of a slice model.

The data for this example comes from the Wisconsin Diagnosis Breast Cancer Database, and is available [here](#). The data was converted to the GAMS file `wdbc.gms`, which defines A and D . The actual source code for the following GAMS formulation is available [here](#).

The GUSS formulation for quadratic svm:

```
$title Ten-fold cross validation example using GUSS
$eolcom !

$setglobal num_folds 10

set p /1*%num_folds%/; ! folds to perform

! Read in data
$include "wdbc.gms"

set test(p,i);          ! testing set

! Define problem
parameter C /1/;
positive variables z(i);
variables obj, w(k), gamma, slack(i);

equations obj_def, sep_def(i);

obj_def..  obj =e= 1/2*sum(k, sqr(w(k))) + C*sum(i, z(i));
sep_def(i)..
            D(i)*(sum(k, A(i,k)*w(k)) - gamma) + z(i) + slack(i) =g= 1;

model train /all/;

! Generate testing sets (to be deleted in each problem)
loop(p,
$batinclude gentestset2.inc "p,i"
);

set headers report / modelstat, solvestat, objval /;
parameter
    scenrep(p,headers)
    scopt / SkipBaseCase 1, LogOption 2 /;

set dict / p.    scenario.''
           scopt.opt.    scenrep
           z.    upper.    iupper
           slack.upper.    ifree /;

Parameter iupper(p,i), ifree(p,i);
iupper(p,i)$(not test(p,i)) = inf;
ifree(p,i)$test(p,i)        = inf;
```

```
option qcp=conopt, optcr=0, optca=0;
solve train using qcp minimizing obj scenario dict;
display scenrep;
```

Because the problem is quadratic, we must use a quadratic program solver. The variable values for weight and gamma could be saved for later testing using the same method as detailed above for the linear case.

The batinclude file [gentestset2.inc](#) is very similar to [gentestset.inc](#) from the earlier cross-validation examples. In [gentestset2.inc](#), though, only one set is being dealt with rather than two. The complete source GAMS code for this formulation is available in this [zip archive](#).

5.23.5.2 DEA Modeling in GAMS via GUSS

Data Envelopment Analysis (DEA) models can be solved most efficiently in GAMS using the Gather-Update-Solve-Scatter (GUSS) facility. This is the preferred method since release 23.7 of GAMS and hence the GAMS/DEA solver is no longer available.

A paper with the title "GUSS: Solving Collections of Data Related Models within GAMS" that contains two additional application examples for GUSS is available [here](#).

5.23.5.2.1 Introduction The basic (CCR) DEA model is a collection of models indexed by k and defined by

$$\begin{array}{llll}
 \max_{u,v} & u^T Y_{*,k} & & \text{(objective slice)} \\
 \text{subject to} & v^T X_{*,k} = 1 & & \text{(slice constraint)} \\
 & u^T Y \leq v^T X & & \text{(core constraint)} \\
 & u, v \geq 0 & & \text{(core constraint)}
 \end{array} \tag{5.13}$$

where X, Y are data matrices.

Without using GUSS in GAMS, a model would be defined and solved in a loop over k , requiring the model to be generated multiple times with different instances for each value of k . GUSS is an alternative (and more efficient) way to define the individual programs and pass them to any underlying GAMS solver. In this way, individual programs are not re-generated, but are instead defined as data modifications of each other. This reduces overall model generation time. Further, previous solutions can be used as starting points in later solves to speed up overall processing time.

Some DEA examples compare the two formulations. The actual source code for both of these formulations is available [here](#).

5.23.5.2.2 DEA Examples Original GAMS formulation (without GUSS): In all these models the model setup and data are given at the top of the file and the code of interest is in the last 10 or so lines. In this setting we loop over the set k and change the data in the objective function and the first constraint of the model explicitly before each solve. We only output a minimal summary of the solution.

```
$title Data Envelopment Analysis - DEA
```

```
$ontext
```

```
Data Envelopment Analysis (DEA) is a technique for measuring the relative
performance of organizational units where presence of multiple inputs and
outputs makes comparison difficult.
```

```
efficiency = weighted sum of output / weighted sum of input
```

Find weights that maximize the efficiency for one unit while ensuring that no other units has an efficiency < 1 using these weights. A primal and dual formulation is presented.

Dyson, Thanassoulis, and Boussofiane, A DEA Tutorial.

solve dea using lp max eff scenario dict;
display scenrep,eff_k;

```

In the GUSS version we indicate the collection of models to be solved using the set `dict`. The first element of `dict` determines the set to be used for the scenario (collection) index, in this case k . The second element of `dict` then details that in each scenario k , the parameter `slice` is instantiated using a slice of the parameter data. Essentially, this corresponds to the GAMS statement:

$$\text{slice}(j) = \text{data}(k,j)$$

Note the scenario index k must appear as the first index of the parameter data. The third element of `dict` allows the modeler to collect information from each solve and store it into a GAMS parameter. Essentially, the third element of `dict` corresponds to the GAMS statement:

$$\text{eff.k}(k) = \text{eff.l}$$

that gets executed immediately after the solve of scenario k .

More complex scenario models can also be formulated using GUSS, including multiple equations being updated. This is shown by the dual of the basic DEA model, given by

$$\begin{array}{lll}
 \min_{z,\lambda} & z & \text{(objective)} \\
 \text{subject to} & X^*\lambda \leq zX_{*,k} & \text{(slice constraint)} \\
 & Y^*\lambda \geq Y_{*,k} & \text{(slice constraint)} \\
 & \lambda \geq 0 & \text{(core constraint)}
 \end{array} \tag{5.14}$$

The next example compares the two formulations for this model. The actual source code for both of these formulations is available [here](#).

Original GAMS formulation (without GUSS):

```

Extensions of these models to formulations with weighted outputs or variable returns to scale are easy to formulate with the scenario solver within GAMS. This extended model can be downloaded [here](#).

The **DEA model** in the model library is similar to the extended model, but does not make use of GUSS.

5.24 IPOPT and IPOPTH

COIN-OR IPOPT (Interior Point Optimizer) is an open-source solver for large-scale nonlinear programming (NLP). The code has been written primarily by Andreas Wächter.

IPOPT implements an interior point line search filter method for nonlinear programming models which functions can be nonconvex, but should be twice continuously differentiable. For more information on the algorithm we refer to [189] [249] [248] [250] [247] and the [IPOPT web site](#). Most of the IPOPT documentation in the section was taken from the IPOPT manual [138] .

5.24.1 The linear solver in IPOPT

The performance and robustness of IPOPT on larger models heavily relies on the used solver for sparse symmetric indefinite linear systems.

GAMS/IPOPT includes the sparse solver **MUMPS** [14] [15] (currently the default), and MKL PARDISO [218] [219] (only Linux, Mac OS X, and Windows). In the commercially licensed GAMS/IPOPTH version, also the Harwell Subroutine Library (HSL) solvers MA27, MA57, HSL_MA86, and HSL_MA97 are available and MA27 is used by default.

MUMPS, MA57, HSL_MA86, and HSL_MA97 use **METIS** for matrix ordering [137], see also the **METIS manual** . METIS is copyrighted by the regents of the University of Minnesota.

IPOPT and IPOPTH can exploit parallelization of the linear solvers MKL Pardiso, HSL MA86, and HSL MA97 and the linear algebra routines (MKL Blas and Lapack).

The linear solver is chosen by the [linear_solver](#) option. Benchmarks have shown that MA57 and HSL_MA97 are often able to outperform MA27 on larger instances. Further, PARDISO often allows for performance that is better than MUMPS and similar to the HSL solvers. If IPOPT fails to solve an instance with PARDISO, it's worth to try changing the options [pardiso_order](#) and [pardiso_max_iterative_refinement_steps](#).

5.24.2 Usage

The following statement can be used inside your GAMS program to specify using IPOPT

```
Option NLP = IPOPT;      { or LP, RMIP, DNLP, RMINLP, QCP, RMIQCP, CNS }
```

The above statement should appear before the Solve statement. If IPOPT was specified as the default solver during GAMS installation, the above statement is not necessary.

To use IPOPTH, the statement should be

```
Option NLP = IPOPTH;     { or LP, RMIP, DNLP, RMINLP, QCP, RMIQCP, CNS }
```

5.24.2.1 Using Harwell Subroutine Library routines with GAMS/IPOPT.

GAMS/IPOPT can use the HSL routines MA27, MA28, MA57, HSL_MA77, HSL_MA86, HSL_MA97, MC19, and HSL_MC68 when provided as shared library. By telling IPOPT to use one of these routines (see options [linear_solver](#), [linear_system_scaling](#), [nlp_scaling_method](#), [dependency_detector](#)), GAMS/IPOPT attempts to load the required routines from the library `libhsl.so` (Unix-Systems), `libhsl.dylib` (MacOS X), or `libhsl.dll` (Windows), respectively.

The HSL routines are available at <http://www.hsl.rl.ac.uk/ipopt>. Note that it is your responsibility to ensure that you are entitled to download and use these routines!

5.24.2.2 Specification of Options

IPOPT has many options that can be adjusted for the algorithm (see Section [List of IPOPT Options](#)). Options are all identified by a string name, and their values can be of one of three types: Number (real), Integer, or String. Number options are used for things like tolerances, integer options are used for things like maximum number of iterations, and string options are used for setting algorithm details, like the NLP scaling method. Options can be set by creating a `ipopt.opt` file in the directory you are executing IPOPT.

The `ipopt.opt` file is read line by line and each line should contain the option name, followed by whitespace, and then the value. Comments can be included with the `#` symbol. For example, the following is a valid `ipopt.opt` file:

```
# This is a comment

# Turn off the NLP scaling
nlp_scaling_method none

# Change the initial barrier parameter
mu_init 1e-2

# Set the max number of iterations
max_iter 500
```

GAMS/IPOPT understands currently the following GAMS parameters: [reslim](#) (time limit), [iterlim](#) (iteration limit), [domlim](#) (domain violation limit). Further the option [threads](#) can be used to control the number of threads used in the [linear algebra routines and the linear solver](#).

5.24.2.3 Warmstarting Ipopt

As an interior point solver, it is difficult to warm start IPOPT. By default, only the level values of the variables are passed as starting point to IPOPT. Setting the IPOPT option `warm_start_init_point` to `yes` enables that also dual values for variables and constraints are passed to IPOPT.

However, the expected behavior that IPOPT finishes within one iteration if optimal primal and dual values are passed is not reached this way, yet. This is, because IPOPT by default moves any initial value that is close to a bound into the interior. The amount on how much the initial point is moved can be controlled by various `bound_push` and `bound_frac` options. To make IPOPT accept an optimal primal/dual solution within one iteration, it should be sufficient to set the following options:

```
warm_start_init_point      yes
warm_start_bound_push      1e-9
warm_start_bound_frac      1e-9
warm_start_slack_bound_frac 1e-9
warm_start_slack_bound_push 1e-9
warm_start_mult_bound_push 1e-9
```

5.24.3 Output

This section describes the standard IPOPT console output. The output is designed to provide a quick summary of each iteration as IPOPT solves the problem.

Before IPOPT starts to solve the problem, it displays the problem statistics (number of nonzero-elements in the matrices, number of variables, etc.). Note that if you have fixed variables (both upper and lower bounds are equal), IPOPT may remove these variables from the problem internally and not include them in the problem statistics.

Following the problem statistics, IPOPT will begin to solve the problem and you will see output resembling the following,

iter	objective	inf_pr	inf_du	lg(mu)	d	lg(rg)	alpha_du	alpha_pr	ls
0	1.6109693e+01	1.12e+01	5.28e-01	0.0	0.00e+00	-	0.00e+00	0.00e+00	0
1	1.8029749e+01	9.90e-01	6.62e+01	0.1	2.05e+00	-	2.14e-01	1.00e+00f	1
2	1.8719906e+01	1.25e-02	9.04e+00	-2.2	5.94e-02	2.0	8.04e-01	1.00e+00h	1

and the columns of output are defined as

item

The current iteration count. This includes regular iterations and iterations while in restoration phase. If the algorithm is in the restoration phase, the letter `r` will be appended to the iteration number.

objective

The unscaled objective value at the current point. During the restoration phase, this value remains the unscaled objective value for the original problem.

inf_pr

The unscaled constraint violation at the current point. This quantity is the infinity-norm (max) of the (unscaled) constraint violation. During the restoration phase, this value remains the constraint violation of the original problem at the current point. The option `inf_pr_output` can be used to switch to the printing of a different quantity. During the restoration phase, this value is the primal infeasibility of the original problem at the current point.

`inf_du`

The scaled dual infeasibility at the current point. This quantity measure the infinity-norm (max) of the internal dual infeasibility (Eq. (4a) in [250]), including inequality constraints reformulated using slack variables and problem scaling. During the restoration phase, this is the value of the dual infeasibility for the restoration phase problem.

`lg(mu)`

$\log_{10}$ of the value of the barrier parameter μ .

`||d||`

The infinity norm (max) of the primal step (for the original variables $\mathbf{x}$ and the internal slack variables $\mathbf{s}$). During the restoration phase, this value includes the values of additional variables, $\mathbf{p}$ and $\mathbf{n}$ in Eq. (10) of [250] .

`lg(rg)`

$\log_{10}$ of the value of the regularization term for the Hessian of the Lagrangian in the augmented system (δ_w in Eq. (26) of [250]). A dash (-) indicates that no regularization was done.

`alpha_du`

The stepsize for the dual variables (α_k^z in Eq. (14c) of [250]).

`alpha_pr`

The stepsize for the primal variables (α_k in Eq. (14a) of [250]). The number is usually followed by a character for additional diagnostic information regarding the step acceptance criterion:

- **f**: f-type iteration in the filter method w/o second order correction
- **F**: f-type iteration in the filter method w/ second order correction
- **h**: h-type iteration in the filter method w/o second order correction
- **H**: h-type iteration in the filter method w/ second order correction
- **k**: penalty value unchanged in merit function method w/o second order correction
- **K**: penalty value unchanged in merit function method w/ second order correction
- **n**: penalty value updated in merit function method w/o second order correction
- **N**: penalty value updated in merit function method w/ second order correction
- **R**: Restoration phase just started
- **w**: in watchdog procedure
- **s**: step accepted in soft restoration phase
- **t/T**: tiny step accepted without line search
- **r**: some previous iterate restored

`ls`

The number of backtracking line search steps (does not include second-order correction steps).

Note that the step acceptance mechanisms in IPOPT consider the barrier objective function (Eq. (3a) in [250]) which is usually different from the value reported in the `objective` column. Similarly, for the purposes of the step acceptance, the constraint violation is measured for the internal problem formulation, which includes slack variables for inequality constraints and potentially scaling of the constraint functions. This value, too, is usually different from the value reported in `inf_pr`. As a consequence, a new iterate might have worse values both for the objective function and the constraint violation as reported in the iteration output, seemingly contradicting globalization procedure.

When the algorithm terminates, IPOPT will output a message to the screen. The following is a list of the possible output messages and a brief description.

Optimal Solution Found.

This message indicates that IPOPT found a (locally) optimal point within the desired tolerances.

Solved To Acceptable Level.

This indicates that the algorithm did not converge to the "desired" tolerances, but that it was able to obtain a point satisfying the "acceptable" tolerance level as specified by `acceptable-*` options. This may happen if the desired tolerances are too small for the current problem.

Feasible point for square problem found.

This message is printed if the problem is "square" (i.e., it has as many equality constraints as free variables) and IPOPT found a feasible point.

Converged to a point of local infeasibility. Problem may be infeasible.

The restoration phase converged to a point that is a minimizer for the constraint violation (in the ℓ_1 -norm), but is not feasible for the original problem. This indicates that the problem may be infeasible (or at least that the algorithm is stuck at a locally infeasible point). The returned point (the minimizer of the constraint violation) might help you to find which constraint is causing the problem. If you believe that the NLP is feasible, it might help to start the optimization from a different point.

Search Direction is becoming Too Small.

This indicates that IPOPT is calculating very small step sizes and making very little progress. This could happen if the problem has been solved to the best numerical accuracy possible given the current scaling.

Iterates diverging; problem might be unbounded.

This message is printed if the max-norm of the iterates becomes larger than the value of the option `diverging_iterates_tol`. This can happen if the problem is unbounded below and the iterates are diverging.

Stopping optimization at current point as requested by user.

This message is printed if either the Ctrl+C was pressed or the domain violation limit is reached.

Maximum Number of Iterations Exceeded.

This indicates that IPOPT has exceeded the maximum number of iterations as specified by the IPOPT option `max_iter` or the GAMS option `iterlim`.

Maximum CPU time exceeded.

This indicates that IPOPT has exceeded the maximum number of seconds as specified by the IPOPT option [max_cpu_time](#) or the GAMS option [reslim](#).

Restoration Failed!

This indicates that the restoration phase failed to find a feasible point that was acceptable to the filter line search for the original problem. This could happen if the problem is highly degenerate or does not satisfy the constraint qualification, or if an external function in GAMS provides incorrect derivative information.

Error in step computation (regularization becomes too large?)!

This message is printed if IPOPT is unable to compute a search direction, despite several attempts to modify the iteration matrix. Usually, the value of the regularization parameter then becomes too large.

Problem has too few degrees of freedom.

This indicates that your problem, as specified, has too few degrees of freedom. This can happen if you have too many equality constraints, or if you fix too many variables (IPOPT removes fixed variables).

Not enough memory.

An error occurred while trying to allocate memory. The problem may be too large for your current memory and swap configuration.

INTERNAL ERROR: Unknown SolverReturn value - Notify IPOPT Authors.

An unknown internal error has occurred. Please notify the authors of the GAMS/IPOPT link or IPOPT (refer to support@gams.com).

5.24.3.1 Diagnostic Tags for IPOPT

To print additional diagnostic tags for each iteration of IPOPT, set the options [print_info_string](#) to **yes**. With this, a tag will appear at the end of an iteration line with the following diagnostic meaning that are useful to flag difficulties for a particular IPOPT run. The following is a list of possible strings:

- **!**: Tighten resto tolerance if only slightly infeasible, see Sec. 3.3 in [\[250\]](#)
 - **A**: Current iteration is acceptable (alternate termination)
 - **a**: Perturbation for PD Singularity can't be done, assume singular, see Sec. 3.1 in [\[250\]](#)
 - **C**: Second Order Correction taken, see Sec. 2.4 in [\[250\]](#)
 - **Dh**: Hessian degenerate based on multiple iterations, see Sec. 3.1 in [\[250\]](#)
 - **Dhj**: Hessian/Jacobian degenerate based on multiple iterations, see Sec. 3.1 in [\[250\]](#)
 - **Dj**: Jacobian degenerate based on multiple iterations, see Sec. 3.1 in [\[250\]](#)
 - **dx**: δ_x perturbation too large, see Sec. 3.1 in [\[250\]](#)
 - **e**: Cutting back α due to evaluation error (in backtracking line search)
 - **F-**: Filter should be reset, but maximal resets exceeded, see Sec. 2.3 in [\[250\]](#)
 - **F+**: Resetting filter due to last few rejections of filter, see Sec. 2.3 in [\[250\]](#)
 - **L**: Degenerate Jacobian, δ_c already perturbed, see Sec. 3.1 in [\[250\]](#)
-

- 1: Degenerate Jacobian, δ_c perturbed, see Sec. 3.1 in [250]
- M: Magic step taken for slack variables (in backtracking line search)
- Nh: Hessian not yet degenerate, see Sec. 3.1 in [250]
- Nhj: Hessian/Jacobian not yet degenerate, see Sec. 3.1 in [250]
- Nj: Jacobian not yet degenerate, see Sec. 3.1 in [250]
- NW: Warm start initialization failed (in Warm Start Initialization)
- q: PD system possibly singular, attempt to improve solution quality, see Sec. 3.1 in [250]
- R: Solution of restoration phase, see Sec. 3.3 in [250]
- S: PD system possibly singular, accept current solution, see Sec. 3.1 in [250]
- s: PD system singular, see Sec. 3.1 in [250]
- s: Square Problem. Set multipliers to zero (default initialization routine)
- Tmax: Trial θ is larger than $\theta_{\max}$ (filter parameter, Eq. (21) in [250])
- W: Watchdog line search procedure successful, see Sec. 3.2 in [250]
- w: Watchdog line search procedure unsuccessful, stopped, see Sec. 3.2 in [250]
- Wb: Undoing most recent SR1 update, see Sec. 5.4.1 in [39]
- We: Skip Limited-Memory Update in restoration phase, see Sec. 5.4.1 in [39]
- Wp: Safeguard $B^0 = \sigma I$ for Limited-Memory Update, see Sec. 5.4.1 in [39]
- Wr: Resetting Limited-Memory Update, see Sec. 5.4.1 in [39]
- Ws: Skip Limited-Memory Update since $s^T y$ is not positive, see Sec. 5.4.1 in [39]
- WS: Skip Limited-Memory Update since Δx is too small, see Sec. 5.4.1 in [39]
- y: Dual infeasibility, use least square multiplier update (during IPOPT algorithm)
- z: Apply correction to bound multiplier if too large (during IPOPT algorithm)

5.24.4 List of IPOPT Options

5.24.4.1 Barrier Parameter Update

Option	Description	Default
adaptive_mu_globalization	Globalization strategy for the adaptive mu selection mode.	obj-constr-filter
adaptive_mu_kkterror_red_fact	Sufficient decrease factor for 'kkt-error' globalization strategy.	0.9999
adaptive_mu_kkterror_red_iters	Maximum number of iterations requiring sufficient progress.	4
adaptive_mu_kkt_norm_type	Norm used for the KKT error in the adaptive mu globalization strategies.	2-norm-squared
adaptive_mu_monotone_init_factor	Determines the initial value of the barrier parameter when switching to the monotone mode.	0.8
adaptive_mu_restore_previous_iterate	Indicates if the previous iterate should be restored if the monotone mode is entered.	no

Option	Description	Default
barrier_tol_factor	Factor for mu in barrier stop test.	10
filter_margin_fact	Factor determining width of margin for obj-constr-filter adaptive globalization strategy.	1e-05
filter_max_margin	Maximum width of margin in obj-constr-filter adaptive globalization strategy.	1
fixed_mu_oracle	Oracle for the barrier parameter when switching to fixed mode.	average_compl
mu_allow_fast_monotone_decrease	Allow skipping of barrier problem if barrier test is already met.	yes
mu_init	Initial value for the barrier parameter.	0.1
mu_linear_decrease_factor	Determines linear decrease rate of barrier parameter.	0.2
mu_max	Maximum value for barrier parameter.	100000
mu_max_fact	Factor for initialization of maximum value for barrier parameter.	1000
mu_min	Minimum value for barrier parameter.	1e-11
mu_oracle	Oracle for a new barrier parameter in the adaptive strategy.	quality-function
mu_strategy	Update strategy for barrier parameter.	adaptive
mu_superlinear_decrease_power	Determines superlinear decrease rate of barrier parameter.	1.5
quality_function_balancing_term	The balancing term included in the quality function for centrality.	none
quality_function_centrality	The penalty term for centrality that is included in quality function.	none
quality_function_max_section_steps	Maximum number of search steps during direct search procedure determining the optimal centering parameter.	8
quality_function_norm_type	Norm used for components of the quality function.	2-norm-squared
quality_function_section_qf_tol	Tolerance for the golden section search procedure determining the optimal centering parameter (in the function value space).	0
quality_function_section_sigma_tol	Tolerance for the section search procedure determining the optimal centering parameter (in sigma space).	0.01
sigma_max	Maximum value of the centering parameter.	100
sigma_min	Minimum value of the centering parameter.	1e-06
tau_min	Lower bound on fraction-to-the-boundary parameter tau.	0.99

5.24.4.2 Convergence

Option	Description	Default
acceptable_compl_inf_tol	'Acceptance' threshold for the complementarity conditions.	0.01
acceptable_constr_viol_tol	'Acceptance' threshold for the constraint violation.	0.01
acceptable_dual_inf_tol	'Acceptance' threshold for the dual infeasibility.	1e+10
acceptable_iter	Number of 'acceptable' iterates before triggering termination.	15
acceptable_obj_change_tol	'Acceptance' stopping criterion based on objective function change.	1e+20
acceptable_tol	'Acceptable' convergence tolerance (relative).	1e-06
compl_inf_tol	Desired threshold for the complementarity conditions.	0.0001
constr_viol_tol	Desired threshold for the constraint violation.	0.0001
diverging_iterates_tol	Threshold for maximal value of primal iterates.	1e+20
dual_inf_tol	Desired threshold for the dual infeasibility.	1
max_cpu_time	Maximum number of CPU seconds.	1000
max_iter	Maximum number of iterations.	maxint
mu_target	Desired value of complementarity.	0
s_max	Scaling threshold for the NLP error.	100
tol	Desired convergence tolerance (relative).	1e-08

5.24.4.3 Hessian Approximation

Option	Description	Default
hessian_approximation	Indicates what Hessian information is to be used.	exact
hessian_approximation_space	Indicates in which subspace the Hessian information is to be approximated.	nonlinear-variables
limited_memory_aug_solver	Strategy for solving the augmented system for low-rank Hessian.	sherman-morrison
limited_memory_initialization	Initialization strategy for the limited memory quasi-Newton approximation.	scalar1
limited_memory_init_val	Value for B0 in low-rank update.	1
limited_memory_init_val_max	Upper bound on value for B0 in low-rank update.	1e+08
limited_memory_init_val_min	Lower bound on value for B0 in low-rank update.	1e-08
limited_memory_max_history	Maximum size of the history for the limited quasi-Newton Hessian approximation.	6
limited_memory_max_skipping	Threshold for successive iterations where update is skipped.	2
limited_memory_special_for_resto	Determines if the quasi-Newton updates should be special during the restoration phase.	no
limited_memory_update_type	Quasi-Newton update formula for the limited memory approximation.	bfgs

5.24.4.4 Initialization

Option	Description	Default
bound_frac	Desired minimum relative distance from the initial point to bound.	0.01
bound_mult_init_method	Initialization method for bound multipliers	constant
bound_mult_init_val	Initial value for the bound multipliers.	1
bound_push	Desired minimum absolute distance from the initial point to bound.	0.01
constr_mult_init_max	Maximum allowed least-square guess of constraint multipliers.	1000
least_square_init_duals	Least square initialization of all dual variables	no
least_square_init_primal	Least square initialization of the primal variables	no
slack_bound_frac	Desired minimum relative distance from the initial slack to bound.	0.01
slack_bound_push	Desired minimum absolute distance from the initial slack to bound.	0.01

5.24.4.5 Line Search

Option	Description	Default
accept_after_max_steps	Accept a trial point after maximal this number of steps.	-1
accept_every_trial_step	Always accept the first trial step.	no
alpha_for_y	Method to determine the step size for constraint multipliers.	primal
alpha_for_y_tol	Tolerance for switching to full equality multiplier steps.	10
alpha_min_frac	Safety factor for the minimal step size (before switching to restoration phase).	0.05
alpha_red_factor	Fractional reduction of the trial step size in the backtracking line search.	0.5
constraint_violation_norm_type	Norm to be used for the constraint violation in the line search.	1-norm
corrector_compl_avrg_red_fact	Complementarity tolerance factor for accepting corrector step.	1
corrector_type	The type of corrector steps that should be taken.	none
delta	Multiplier for constraint violation in the switching rule.	1
eta_phi	Relaxation factor in the Armijo condition.	1e-08
filter_reset_trigger	Number of iterations that trigger the filter reset.	5
gamma_phi	Relaxation factor in the filter margin for the barrier function.	1e-08
gamma_theta	Relaxation factor in the filter margin for the constraint violation.	1e-05
kappa_sigma	Factor limiting the deviation of dual variables from primal estimates.	1e+10
kappa_soc	Factor in the sufficient reduction rule for second order correction.	0.99

Option	Description	Default
line_search_method	Globalization method used in backtracking line search	filter
max_filter_resets	Maximal allowed number of filter resets	5
max_soc	Maximum number of second order correction trial steps at each iteration.	4
nu_inc	Increment of the penalty parameter.	0.0001
nu_init	Initial value of the penalty parameter.	1e-06
obj_max_inc	Determines the upper bound on the acceptable increase of barrier objective function.	5
recalc_y	Tells the algorithm to recalculate the equality and inequality multipliers as least square estimates.	no
recalc_y_feas_tol	Feasibility threshold for recomputation of multipliers.	1e-06
rho	Value in penalty parameter update formula.	0.1
skip_corr_if_neg_curv	Skip the corrector step in negative curvature iteration.	yes
skip_corr_in_monotone_mode	Skip the corrector step during monotone barrier parameter mode.	yes
slack_move	Correction size for very small slacks.	1.81899e-12
soc_method	Ways to apply second order correction	0
s_phi	Exponent for linear barrier function model in the switching rule.	2.3
s_theta	Exponent for current constraint violation in the switching rule.	1.1
theta_max_fact	Determines upper bound for constraint violation in the filter.	10000
theta_min_fact	Determines constraint violation threshold in the switching rule.	0.0001
tiny_step_tol	Tolerance for detecting numerically insignificant steps.	2.22045e-15
tiny_step_y_tol	Tolerance for quitting because of numerically insignificant steps.	0.01
watchdog_shortened_iter_trigger	Number of shortened iterations that trigger the watchdog.	10
watchdog_trial_iter_max	Maximum number of watchdog iterations.	3

5.24.4.6 Linear Solver

Option	Description	Default
linear_scaling_on_demand	Flag indicating that linear scaling is only done if it seems required.	yes
linear_solver	Linear solver used for step computations.	ma27
linear_system_scaling	Method for scaling the linear system.	mc19

5.24.4.7 MA27 Linear Solver

Option	Description	Default
ma27_ignore_singularity	Enables MA27's ability to solve a linear system even if the matrix is singular.	no
ma27_la_init_factor	Real workspace memory for MA27.	5
ma27_liw_init_factor	Integer workspace memory for MA27.	5
ma27_meminc_factor	Increment factor for workspace size for MA27.	2
ma27_pivtol	Pivot tolerance for the linear solver MA27.	1e-08
ma27_pivtolmax	Maximum pivot tolerance for the linear solver MA27.	0.0001
ma27_skip_inertia_check	Always pretend inertia is correct.	no

5.24.4.8 MA28 Linear Solver

Option	Description	Default
ma28_pivtol	Pivot tolerance for linear solver MA28.	0.01

5.24.4.9 MA57 Linear Solver

Option	Description	Default
ma57_automatic_scaling	Controls MA57 automatic scaling	no
ma57_block_size	Controls block size used by Level 3 BLAS in MA57BD	16
ma57_node_amalgamation	Node amalgamation parameter	16
ma57_pivot_order	Controls pivot order in MA57	5
ma57_pivtol	Pivot tolerance for the linear solver MA57.	1e-08
ma57_pivtolmax	Maximum pivot tolerance for the linear solver MA57.	0.0001
ma57_pre_alloc	Safety factor for work space memory allocation for the linear solver MA57.	1.05
ma57_small_pivot_flag	If set to 1, then when small entries defined by CNTL(2) are detected they are removed and the corresponding pivots placed at the end of the factorization. This can be particularly efficient if the matrix is highly rank deficient.	0

5.24.4.10 MA77 Linear Solver

Option	Description	Default
ma77_buffer_lpage	Number of scalars per MA77 buffer page	4096
ma77_buffer_npage	Number of pages that make up MA77 buffer	1600
ma77_file_size	Target size of each temporary file for MA77, scalars per type	2097152
ma77_maxstore	Maximum storage size for MA77 in-core mode	0
ma77_nemin	Node Amalgamation parameter	8

Option	Description	Default
ma77_order	Controls type of ordering used by HSL_MA77	<code>metis</code>
ma77_print_level	Debug printing level for the linear solver MA77	<code>-1</code>
ma77_small	Zero Pivot Threshold	<code>1e-20</code>
ma77_static	Static Pivoting Threshold	<code>0</code>
ma77_u	Pivoting Threshold	<code>1e-08</code>
ma77_umax	Maximum Pivoting Threshold	<code>0.0001</code>

5.24.4.11 MA86 Linear Solver

Option	Description	Default
ma86_nemin	Node Amalgamation parameter	<code>32</code>
ma86_order	Controls type of ordering used by HSL_MA86	<code>auto</code>
ma86_print_level	Debug printing level for the linear solver MA86	<code>-1</code>
ma86_scaling	Controls scaling of matrix	<code>mc64</code>
ma86_small	Zero Pivot Threshold	<code>1e-20</code>
ma86_static	Static Pivoting Threshold	<code>0</code>
ma86_u	Pivoting Threshold	<code>1e-08</code>
ma86_umax	Maximum Pivoting Threshold	<code>0.0001</code>

5.24.4.12 MA97 Linear Solver

Option	Description	Default
ma97_nemin	Node Amalgamation parameter	<code>8</code>
ma97_order	Controls type of ordering used by HSL_MA97	<code>auto</code>
ma97_print_level	Debug printing level for the linear solver MA97	<code>0</code>
ma97_scaling	Specifies strategy for scaling in HSL_MA97 linear solver	<code>dynamic</code>
ma97_scaling1	First scaling.	<code>mc64</code>
ma97_scaling2	Second scaling.	<code>mc64</code>
ma97_scaling3	Third scaling.	<code>mc64</code>
ma97_small	Zero Pivot Threshold	<code>1e-20</code>
ma97_solve_blas3	Controls if blas2 or blas3 routines are used for solve	<code>no</code>
ma97_switch1	First switch, determine when <code>ma97_scaling1</code> is enabled.	<code>od_hd_reuse</code>
ma97_switch2	Second switch, determine when <code>ma97_scaling2</code> is enabled.	<code>never</code>
ma97_switch3	Third switch, determine when <code>ma97_scaling3</code> is enabled.	<code>never</code>
ma97_u	Pivoting Threshold	<code>1e-08</code>
ma97_umax	Maximum Pivoting Threshold	<code>0.0001</code>

5.24.4.13 Mumps Linear Solver

Option	Description	Default
mumps_dep_tol	Pivot threshold for detection of linearly dependent constraints in MUMPS.	0
mumps_mem_percent	Percentage increase in the estimated working space for MUMPS.	1000
mumps_permuting_scaling	Controls permuting and scaling in MUMPS	7
mumps_pivot_order	Controls pivot order in MUMPS	7
mumps_pivtol	Pivot tolerance for the linear solver MUMPS.	1e-06
mumps_pivtolmax	Maximum pivot tolerance for the linear solver MUMPS.	0.1
mumps_scaling	Controls scaling in MUMPS	77

5.24.4.14 NLP

Option	Description	Default
bound_relax_factor	Factor for initial relaxation of the bounds.	1e-10
check_derivatives_for_naninf	Indicates whether it is desired to check for Nan/Inf in derivative matrices	no
dependency_detection_with_rhs	Indicates if the right hand sides of the constraints should be considered during dependency detection	no
dependency_detector	Indicates which linear solver should be used to detect linearly dependent equality constraints.	none
fixed_variable_treatment	Determines how fixed variables should be handled.	make_parameter
honor_original_bounds	Indicates whether final points should be projected into original bounds.	yes
jac_c_constant	Indicates whether all equality constraints are linear	no
jac_d_constant	Indicates whether all inequality constraints are linear	no
kappa_d	Weight for linear damping term (to handle one-sided bounds).	1e-05

5.24.4.15 NLP Scaling

Option	Description	Default
nlp_scaling_constr_target_gradient	Target value for constraint function gradient size.	0
nlp_scaling_max_gradient	Maximum gradient after NLP scaling.	100
nlp_scaling_method	Select the technique used for scaling the NLP.	gradient-based
nlp_scaling_min_value	Minimum value of gradient-based scaling values.	1e-08
nlp_scaling_obj_target_gradient	Target value for objective function gradient size.	0

5.24.4.16 Output

Option	Description	Default
inf_pr_output	Determines what value is printed in the 'inf_pr' output column.	original
print_eval_error	Switch to enable printing information about function evaluation errors into the GAMS listing file.	yes
print_frequency_iter	Determines at which iteration frequency the summarizing iteration output line should be printed.	1
print_frequency_time	Determines at which time frequency the summarizing iteration output line should be printed.	0
print_info_string	Enables printing of additional info string at end of iteration output.	no
print_level	Output verbosity level.	5
print_timing_statistics	Switch to print timing statistics.	no
replace_bounds	Indicates if all variable bounds should be replaced by inequality constraints	no
report_mininfeas_solution	Switch to report intermediate solution with minimal constraint violation to GAMS if the final solution is not feasible.	no

5.24.4.17 Pardiso Linear Solver

Option	Description	Default
pardiso_matching_strategy	Matching strategy to be used by Pardiso	complete+2x2
pardiso_max_iterative_refinement_steps	Limit on number of iterative refinement steps.	1
pardiso_msglvl	Pardiso message level	0
pardiso_order	Controls the fill-in reduction ordering algorithm for the input matrix.	metis
pardiso_redo_symbolic_fact_only_if_inertia_wrong	Toggle for handling case when elements were perturbed by Pardiso.	no
pardiso_repeated_perturbation_means_singular	Interpretation of perturbed elements.	no
pardiso_skip_inertia_check	Always pretend inertia is correct.	no

5.24.4.18 Restoration Phase

Option	Description	Default
bound_mult_reset_threshold	Threshold for resetting bound multipliers after the restoration phase.	1000
constr_mult_reset_threshold	Threshold for resetting equality and inequality multipliers after restoration phase.	0
evaluate_orig_obj_at_resto_trial	Determines if the original objective function should be evaluated at restoration phase trial points.	yes
expect_infeasible_problem	Enable heuristics to quickly detect an infeasible problem.	no
expect_infeasible_problem_ctol	Threshold for disabling 'expect_infeasible_problem' option.	0.001

Option	Description	Default
expect_infeasible_problem_ymol	Multiplier threshold for activating 'expect_infeasible_problem' option.	1e+08
max_resto_iter	Maximum number of successive iterations in restoration phase.	3000000
max_soft_resto_iters	Maximum number of iterations performed successively in soft restoration phase.	10
required_infeasibility_reduction	Required reduction of infeasibility before leaving restoration phase.	0.9
resto_failure_feasibility_threshold	Threshold for primal infeasibility to declare failure of restoration phase.	0
resto_penalty_parameter	Penalty parameter in the restoration phase objective function.	1000
resto_proximity_weight	Weighting factor for the proximity term in restoration phase objective.	1
soft_resto_pderror_reduction_factor	Required reduction in primal-dual error in the soft restoration phase.	0.9999
start_with_resto	Tells algorithm to switch to restoration phase in first iteration.	no

5.24.4.19 Step Calculation

Option	Description	Default
fast_step_computation	Indicates if the linear system should be solved quickly.	no
first_hessian_perturbation	Size of first x-s perturbation tried.	0.0001
jacobian_regularization_exponent	Exponent for mu in the regularization for rank-deficient constraint Jacobians.	0.25
jacobian_regularization_value	Size of the regularization for rank-deficient constraint Jacobians.	1e-08
max_hessian_perturbation	Maximum value of regularization parameter for handling negative curvature.	1e+20
max_refinement_steps	Maximum number of iterative refinement steps per linear system solve.	10
mehrotra_algorithm	Indicates if we want to do Mehrotra's algorithm.	no
min_hessian_perturbation	Smallest perturbation of the Hessian block.	1e-20
min_refinement_steps	Minimum number of iterative refinement steps per linear system solve.	1
neg_curv_test_reg	Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014).	yes
neg_curv_test_tol	Tolerance for heuristic to ignore wrong inertia.	0
perturb_always_cd	Active permanent perturbation of constraint linearization.	no
perturb_dec_fact	Decrease factor for x-s perturbation.	0.333333
perturb_inc_fact	Increase factor for x-s perturbation.	8
perturb_inc_fact_first	Increase factor for x-s perturbation for very first perturbation.	100
residual_improvement_factor	Minimal required reduction of residual test ratio in iterative refinement.	1

Option	Description	Default
residual_ratio_max	Iterative refinement tolerance	1e-10
residual_ratio_singular	Threshold for declaring linear system singular after failed iterative refinement.	1e-05

5.24.4.20 Warm Start

Option	Description	Default
warm_start_bound_frac	same as <code>bound_frac</code> for the regular initializer.	0.001
warm_start_bound_push	same as <code>bound_push</code> for the regular initializer.	0.001
warm_start_init_point	Warm-start for initial point	no
warm_start_mult_bound_push	same as <code>mult_bound_push</code> for the regular initializer.	0.001
warm_start_mult_init_max	Maximum initial value for the equality multipliers.	1e+06
warm_start_slack_bound_frac	same as <code>slack_bound_frac</code> for the regular initializer.	0.001
warm_start_slack_bound_push	same as <code>slack_bound_push</code> for the regular initializer.	0.001

5.24.5 Detailed Options Description

acceptable_compl_inf_tol (*real*): 'Acceptance' threshold for the complementarity conditions. [↔](#)

Absolute tolerance on the complementarity. "Acceptable" termination requires that the max-norm of the (unscaled) complementarity is less than this threshold; see also `acceptable_tol`.

Default: 0.01

acceptable_constr_viol_tol (*real*): 'Acceptance' threshold for the constraint violation. [↔](#)

Absolute tolerance on the constraint violation. "Acceptable" termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold; see also `acceptable_tol`.

Default: 0.01

acceptable_dual_inf_tol (*real*): 'Acceptance' threshold for the dual infeasibility. [↔](#)

Absolute tolerance on the dual infeasibility. "Acceptable" termination requires that the (max-norm of the unscaled) dual infeasibility is less than this threshold; see also `acceptable_tol`.

Default: 1e+10

acceptable_iter (*integer*): Number of 'acceptable' iterates before triggering termination. [↔](#)

If the algorithm encounters this many successive "acceptable" iterates (see "acceptable_tol"), it terminates, assuming that the problem has been solved to best possible accuracy given round-off. If it is set to zero, this heuristic is disabled.

Default: 15

acceptable_obj_change_tol (*real*): 'Acceptance' stopping criterion based on objective function change. [↔](#)

If the relative change of the objective function (scaled by $\text{Max}(1, |f(x)|)$) is less than this value, this part of the acceptable tolerance termination is satisfied; see also `acceptable_tol`. This is useful for the quasi-Newton option, which has trouble to bring down the dual infeasibility.

Default: `1e+20`

acceptable_tol (*real*): 'Acceptable' convergence tolerance (relative). [↔](#)

Determines which (scaled) overall optimality error is considered to be "acceptable." There are two levels of termination criteria. If the usual "desired" tolerances (see `tol`, `dual_inf_tol` etc) are satisfied at an iteration, the algorithm immediately terminates with a success message. On the other hand, if the algorithm encounters "acceptable_iter" many iterations in a row that are considered "acceptable", it will terminate before the desired convergence tolerance is met. This is useful in cases where the algorithm might not be able to achieve the "desired" level of accuracy.

Default: `1e-06`

accept_after_max_steps (*integer*): Accept a trial point after maximal this number of steps. [↔](#)

Even if it does not satisfy line search conditions.

Range: $[-1, \infty]$

Default: `-1`

accept_every_trial_step (*string*): Always accept the first trial step. [↔](#)

Setting this option to "yes" essentially disables the line search and makes the algorithm take aggressive steps, without global convergence guarantees.

Default: `no`

value	meaning
no	don't arbitrarily accept the full step
yes	always accept the full step

adaptive_mu_globalization (*string*): Globalization strategy for the adaptive mu selection mode. [↔](#)

To achieve global convergence of the adaptive version, the algorithm has to switch to the monotone mode (Fiacco-McCormick approach) when convergence does not seem to appear. This option sets the criterion used to decide when to do this switch. (Only used if option "mu_strategy" is chosen as "adaptive".)

Default: `obj-constr-filter`

value	meaning
kkt-error	nonmonotone decrease of kkt-error
never-monotone-mode	disables globalization
obj-constr-filter	2-dim filter for objective and constraint violation

adaptive_mu_kkterror_red_fact (*real*): Sufficient decrease factor for 'kkt-error' globalization strategy. [↔](#)

For the "kkt-error" based globalization strategy, the error must decrease by this factor to be deemed sufficient decrease.

Range: [0, 1]

Default: 0.9999

adaptive_mu_kkterror_red_iters (*integer*): Maximum number of iterations requiring sufficient progress. [↩](#)

For the "kkt-error" based globalization strategy, sufficient progress must be made for "adaptive_mu_kkterror_red_iters" iterations. If this number of iterations is exceeded, the globalization strategy switches to the monotone mode.

Default: 4

adaptive_mu_kkt_norm_type (*string*): Norm used for the KKT error in the adaptive mu globalization strategies. [↩](#)

When computing the KKT error for the globalization strategies, the norm to be used is specified with this option. Note, this options is also used in the QualityFunctionMuOracle.

Default: 2-norm-squared

value	meaning
1-norm	use the 1-norm (abs sum)
2-norm	use 2-norm
2-norm-squared	use the 2-norm squared (sum of squares)
max-norm	use the infinity norm (max)

adaptive_mu_monotone_init_factor (*real*): Determines the initial value of the barrier parameter when switching to the monotone mode. [↩](#)

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode and fixed_mu_oracle is chosen as "average_compl", the barrier parameter is set to the current average complementarity times the value of "adaptive_mu_monotone_init_factor".

Default: 0.8

adaptive_mu_restore_previous_iterate (*string*): Indicates if the previous iterate should be restored if the monotone mode is entered. [↩](#)

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode, it can either start from the most recent iterate (no), or from the last iterate that was accepted (yes).

Default: no

value	meaning
no	don't restore accepted iterate
yes	restore accepted iterate

alpha_for_y (*string*): Method to determine the step size for constraint multipliers. [↩](#)

This option determines how the step size (`alpha_y`) will be calculated when updating the constraint multipliers.

Default: `primal`

value	meaning
<code>acceptor</code>	Call <code>LSAcceptor</code> to get step size for <code>y</code>
<code>bound-mult</code>	use step size for the bound multipliers (good for LPs)
<code>dual-and-full</code>	use the dual step size, and full step if $\delta x \leq \alpha_{\text{for\_y\_tol}}$
<code>full</code>	take a full step of size one
<code>max</code>	use the max of primal and bound multipliers
<code>min</code>	use the min of primal and bound multipliers
<code>min-dual-infeas</code>	choose step size minimizing new dual infeasibility
<code>primal</code>	use primal step size
<code>primal-and-full</code>	use the primal step size, and full step if $\delta x \leq \alpha_{\text{for\_y\_tol}}$
<code>safer-min-dual-infeas</code>	like ' <code>min_dual_infeas</code> ', but safeguarded by ' <code>min</code> ' and ' <code>max</code> '

`alpha_for_y_tol` (*real*): Tolerance for switching to full equality multiplier steps. [↔](#)

This is only relevant if "`alpha_for_y`" is chosen "`primal-and-full`" or "`dual-and-full`". The step size for the equality constraint multipliers is taken to be one if the max-norm of the primal step is less than this tolerance.

Default: 10

`alpha_min_frac` (*real*): Safety factor for the minimal step size (before switching to restoration phase). [↔](#)

(This is γ_{α} in Eqn. (20) in the implementation paper.)

Range: [0, 1]

Default: 0.05

`alpha_red_factor` (*real*): Fractional reduction of the trial step size in the backtracking line search. [↔](#)

At every step of the backtracking line search, the trial step size is reduced by this factor.

Range: [0, 1]

Default: 0.5

`barrier_tol_factor` (*real*): Factor for μ in barrier stop test. [↔](#)

The convergence tolerance for each barrier problem in the monotone mode is the value of the barrier parameter times "`barrier_tol_factor`". This option is also used in the adaptive μ strategy during the monotone mode. (This is κ_{ϵ} in implementation paper).

Default: 10

`bound_frac` (*real*): Desired minimum relative distance from the initial point to bound. [↔](#)

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "`bound_push`"). (This is κ_2 in Section 3.6 of implementation paper.)

Range: [0, 0.5]

Default: 0.01

`bound_mult_init_method` (*string*): Initialization method for bound multipliers [↔](#)

This option defines how the iterates for the bound multipliers are initialized. If "`constant`" is chosen, then all bound multipliers are initialized to the value of "`bound_mult_init_val`". If "`mu-based`" is chosen, the each value is initialized to the the value of "`mu_init`" divided by the corresponding slack variable. This latter option might be useful if the starting point is close to the optimal solution.

Default: `constant`

value	meaning
constant	set all bound multipliers to the value of bound_mult_init_val
mu-based	initialize to mu_init/x_slack

bound_mult_init_val (*real*): Initial value for the bound multipliers. [↔](#)

All dual variables corresponding to bound constraints are initialized to this value.

Default: 1

bound_mult_reset_threshold (*real*): Threshold for resetting bound multipliers after the restoration phase. [↔](#)

After returning from the restoration phase, the bound multipliers are updated with a Newton step for complementarity. Here, the change in the primal variables during the entire restoration phase is taken to be the corresponding primal Newton step. However, if after the update the largest bound multiplier exceeds the threshold specified by this option, the multipliers are all reset to 1.

Default: 1000

bound_push (*real*): Desired minimum absolute distance from the initial point to bound. [↔](#)

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)

Default: 0.01

bound_relax_factor (*real*): Factor for initial relaxation of the bounds. [↔](#)

Before start of the optimization, the bounds given by the user are relaxed. This option sets the factor for this relaxation. If it is set to zero, then bounds relaxation is disabled. (See Eqn.(35) in implementation paper.)

Default: 1e-10

check_derivatives_for_naninf (*string*): Indicates whether it is desired to check for Nan/Inf in derivative matrices [↔](#)

Activating this option will cause an error if an invalid number is detected in the constraint Jacobians or the Lagrangian Hessian. If this is not activated, the test is skipped, and the algorithm might proceed with invalid numbers and fail. If test is activated and an invalid number is detected, the matrix is written to output with print_level corresponding to J_MORE_DETAILED; so beware of large output!

Default: no

value	meaning
no	Don't check (faster).
yes	Check Jacobians and Hessian for Nan and Inf.

compl_inf_tol (*real*): Desired threshold for the complementarity conditions. [↔](#)

Absolute tolerance on the complementarity. Successful termination requires that the max-norm of the (unscaled) complementarity is less than this threshold.

Default: 0.0001

constraint_violation_norm_type (*string*): Norm to be used for the constraint violation in the line search. [↩](#)

Determines which norm should be used when the algorithm computes the constraint violation in the line search.

Default: 1-norm

value	meaning
1-norm	use the 1-norm
2-norm	use the 2-norm
max-norm	use the infinity norm

constr_mult_init_max (*real*): Maximum allowed least-square guess of constraint multipliers. [↩](#)

Determines how large the initial least-square guesses of the constraint multipliers are allowed to be (in max-norm). If the guess is larger than this value, it is discarded and all constraint multipliers are set to zero. This options is also used when initializing the restoration phase. By default, "resto.constr_mult_init_max" (the one used in RestoIterateInitializer) is set to zero.

Default: 1000

constr_mult_reset_threshold (*real*): Threshold for resetting equality and inequality multipliers after restoration phase. [↩](#)

After returning from the restoration phase, the constraint multipliers are recomputed by a least square estimate. This option triggers when those least-square estimates should be ignored.

Default: 0

constr_viol_tol (*real*): Desired threshold for the constraint violation. [↩](#)

Absolute tolerance on the constraint violation. Successful termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold.

Default: 0.0001

corrector_compl_avrg_red_fact (*real*): Complementarity tolerance factor for accepting corrector step. [↩](#)

This option determines the factor by which complementarity is allowed to increase for a corrector step to be accepted. Changing this option is experimental.

Default: 1

corrector_type (*string*): The type of corrector steps that should be taken. [↩](#)

If "mu_strategy" is "adaptive", this option determines what kind of corrector steps should be tried. Changing this option is experimental.

Default: none

value	meaning
affine	corrector step towards $\mu=0$
none	no corrector
primal-dual	corrector step towards current μ

delta (*real*): Multiplier for constraint violation in the switching rule. [↔](#)

(See Eqn. (19) in the implementation paper.)

Default: 1

dependency_detection_with_rhs (*string*): Indicates if the right hand sides of the constraints should be considered during dependency detection [↔](#)

Default: no

value	meaning
no	only look at gradients
yes	also consider right hand side

dependency_detector (*string*): Indicates which linear solver should be used to detect linearly dependent equality constraints. [↔](#)

The default and available choices depend on how Ipopt has been compiled. This is experimental and does not work well.

Default: none

value	meaning
ma28	use MA28
mumps	use MUMPS
none	don't check; no extra work at beginning

diverging_iterates_tol (*real*): Threshold for maximal value of primal iterates. [↔](#)

If any component of the primal iterates exceeded this value (in absolute terms), the optimization is aborted with the exit message that the iterates seem to be diverging.

Default: $1e+20$

dual_inf_tol (*real*): Desired threshold for the dual infeasibility. [↔](#)

Absolute tolerance on the dual infeasibility. Successful termination requires that the max-norm of the (unscaled) dual infeasibility is less than this threshold.

Default: 1

eta_phi (*real*): Relaxation factor in the Armijo condition. [↔](#)

(See Eqn. (20) in the implementation paper)

Range: $[0, 0.5]$

Default: $1e-08$

evaluate_orig_obj_at_resto_trial (*string*): Determines if the original objective function should be evaluated at restoration phase trial points. [↔](#)

Setting this option to "yes" makes the restoration phase algorithm evaluate the objective function of the original problem at every trial point encountered during the restoration phase, even if this value is not required. In this way, it is guaranteed that the original objective function can be evaluated without error at all accepted iterates; otherwise the algorithm might fail at a point where the restoration phase accepts an iterate that is good for the restoration phase problem, but not the original problem. On the other hand, if the evaluation of the original objective is expensive, this might be costly.

Default: yes

value	meaning
no	skip evaluation
yes	evaluate at every trial point

expect_infeasible_problem (*string*): Enable heuristics to quickly detect an infeasible problem. [↔](#)

This options is meant to activate heuristics that may speed up the infeasibility determination if you expect that there is a good chance for the problem to be infeasible. In the filter line search procedure, the restoration phase is called more quickly than usually, and more reduction in the constraint violation is enforced before the restoration phase is left. If the problem is square, this option is enabled automatically.

Default: no

value	meaning
no	the problem probably be feasible
yes	the problem has a good chance to be infeasible

expect_infeasible_problem_ctol (*real*): Threshold for disabling 'expect_infeasible_problem' option. [↔](#)

If the constraint violation becomes smaller than this threshold, the "expect_infeasible_problem" heuristics in the filter line search are disabled. If the problem is square, this options is set to 0.

Default: 0.001

expect_infeasible_problem_ytol (*real*): Multiplier threshold for activating 'expect_infeasible_problem' option. [↔](#)

If the max norm of the constraint multipliers becomes larger than this value and "expect_infeasible_problem" is chosen, then the restoration phase is entered.

Default: 1e+08

fast_step_computation (*string*): Indicates if the linear system should be solved quickly. [↔](#)

If set to yes, the algorithm assumes that the linear system that is solved to obtain the search direction, is solved sufficiently well. In that case, no residuals are computed, and the computation of the search direction is a little faster.

Default: no

value	meaning
no	Verify solution of linear system by computing residuals.
yes	Trust that linear systems are solved well.

filter_margin_fact (*real*): Factor determining width of margin for obj-constr-filter adaptive globalization strategy. [↩](#)

When using the adaptive globalization strategy, "obj-constr-filter", sufficient progress for a filter entry is defined as follows: (new obj) < (filter obj) - filter_margin_fact*(new constr-viol) OR (new constr-viol) < (filter constr-viol) - filter_margin_fact*(new constr-viol). For the description of the "kkt-error-filter" option see "filter_max_margin".

Range: [0, 1]

Default: 1e-05

filter_max_margin (*real*): Maximum width of margin in obj-constr-filter adaptive globalization strategy. [↩](#)

Default: 1

filter_reset_trigger (*integer*): Number of iterations that trigger the filter reset. [↩](#)

If the filter reset heuristic is active and the number of successive iterations in which the last rejected trial step size was rejected because of the filter, the filter is reset.

Range: [1, ∞]

Default: 5

first_hessian_perturbation (*real*): Size of first x-s perturbation tried. [↩](#)

The first value tried for the x-s perturbation in the inertia correction scheme.(This is delta_0 in the implementation paper.)

Default: 0.0001

fixed_mu_oracle (*string*): Oracle for the barrier parameter when switching to fixed mode. [↩](#)

Determines how the first value of the barrier parameter should be computed when switching to the "monotone mode" in the adaptive strategy. (Only considered if "adaptive" is selected for option "mu_strategy".)

Default: average_compl

value	meaning
average_compl	base on current average complementarity
loqo	LOQO's centrality rule
probing	Mehrotra's probing heuristic
quality-function	minimize a quality function

fixed_variable_treatment (*string*): Determines how fixed variables should be handled. [↩](#)

The main difference between those options is that the starting point in the "make_constraint" case still has the fixed variables at their given values, whereas in the case "make_parameter" the functions are always evaluated with the fixed values for those variables. Also, for "relax_bounds", the fixing bound constraints are relaxed (according to "bound_relax_factor"). For both "make_constraints" and "relax_bounds", bound multipliers are computed for the fixed variables.

Default: `make_parameter`

value	meaning
<code>make_constraint</code>	Add equality constraints fixing variables
<code>make_parameter</code>	Remove fixed variable from optimization variables
<code>relax_bounds</code>	Relax fixing bound constraints

gamma_phi (*real*): Relaxation factor in the filter margin for the barrier function. [↩](#)

(See Eqn. (18a) in the implementation paper.)

Range: [0, 1]

Default: `1e-08`

gamma_theta (*real*): Relaxation factor in the filter margin for the constraint violation. [↩](#)

(See Eqn. (18b) in the implementation paper.)

Range: [0, 1]

Default: `1e-05`

hessian_approximation (*string*): Indicates what Hessian information is to be used. [↩](#)

This determines which kind of information for the Hessian of the Lagrangian function is used by the algorithm.

Default: `exact`

value	meaning
<code>exact</code>	Use second derivatives provided by the NLP.
<code>limited-memory</code>	Perform a limited-memory quasi-Newton approximation

hessian_approximation_space (*string*): Indicates in which subspace the Hessian information is to be approximated. [↩](#)

Default: `nonlinear-variables`

value	meaning
<code>all-variables</code>	in space of all variables (without slacks)
<code>nonlinear-variables</code>	only in space of nonlinear variables.

honor_original_bounds (*string*): Indicates whether final points should be projected into original bounds. [↩](#)

Ipopt might relax the bounds during the optimization (see, e.g., option "bound_relax_factor"). This option determines whether the final point should be projected back into the user-provide original bounds after the optimization.

Default: **yes**

value	meaning
no	Leave final point unchanged
yes	Project final point back into original bounds

inf_pr_output (*string*): Determines what value is printed in the 'inf_pr' output column. [↩](#)

Ipopt works with a reformulation of the original problem, where slacks are introduced and the problem might have been scaled. The choice "internal" prints out the constraint violation of this formulation. With "original" the true constraint violation in the original NLP is printed.

Default: **original**

value	meaning
internal	max-norm of violation of internal equality constraints
original	maximal constraint violation in original NLP

jacobian_regularization_exponent (*real*): Exponent for mu in the regularization for rank-deficient constraint Jacobians. [↩](#)

(This is kappa_c in the implementation paper.)

Default: 0.25

jacobian_regularization_value (*real*): Size of the regularization for rank-deficient constraint Jacobians. [↩](#)

(This is bar delta_c in the implementation paper.)

Default: 1e-08

jac_c_constant (*string*): Indicates whether all equality constraints are linear [↩](#)

Activating this option will cause Ipopt to ask for the Jacobian of the equality constraints only once from the NLP and reuse this information later.

Default: **no**

value	meaning
no	Don't assume that all equality constraints are linear
yes	Assume that equality constraints Jacobian are constant

jac_d_constant (*string*): Indicates whether all inequality constraints are linear [↩](#)

Activating this option will cause Ipopt to ask for the Jacobian of the inequality constraints only once from the NLP and reuse this information later.

Default: **no**

value	meaning
no	Don't assume that all inequality constraints are linear
yes	Assume that equality constraints Jacobian are constant

kappa_d (*real*): Weight for linear damping term (to handle one-sided bounds). ↩

(see Section 3.7 in implementation paper.)

Default: 1e-05

kappa_sigma (*real*): Factor limiting the deviation of dual variables from primal estimates. ↩

If the dual variables deviate from their primal estimates, a correction is performed. (See Eqn. (16) in the implementation paper.) Setting the value to less than 1 disables the correction.

Default: 1e+10

kappa_soc (*real*): Factor in the sufficient reduction rule for second order correction. ↩

This option determines how much a second order correction step must reduce the constraint violation so that further correction steps are attempted. (See Step A-5.9 of Algorithm A in the implementation paper.)

Default: 0.99

least_square_init_duals (*string*): Least square initialization of all dual variables ↩

If set to yes, Ipopt tries to compute least-square multipliers (considering ALL dual variables). If successful, the bound multipliers are possibly corrected to be at least bound_mult_init_val. This might be useful if the user doesn't know anything about the starting point, or for solving an LP or QP. This overwrites option "bound_mult_init_method".

Default: no

value	meaning
no	use bound_mult_init_val and least-square equality constraint multipliers
yes	overwrite user-provided point with least-square estimates

least_square_init_primal (*string*): Least square initialization of the primal variables ↩

If set to yes, Ipopt ignores the user provided point and solves a least square problem for the primal variables (x and s), to fit the linearized equality and inequality constraints. This might be useful if the user doesn't know anything about the starting point, or for solving an LP or QP.

Default: no

value	meaning
no	take user-provided point
yes	overwrite user-provided point with least-square estimates

limited_memory_aug_solver (*string*): Strategy for solving the augmented system for low-rank Hessian. ↩

Default: `sherman-morrison`

value	meaning
<code>extended</code>	use an extended augmented system
<code>sherman-morrison</code>	use Sherman-Morrison formula

limited_memory_initialization (*string*): Initialization strategy for the limited memory quasi-Newton approximation. [↩](#)

Determines how the diagonal Matrix B_0 as the first term in the limited memory approximation should be computed.

Default: `scalar1`

value	meaning
<code>constant</code>	$\sigma = \text{limited\_memory\_init\_val}$
<code>scalar1</code>	$\sigma = s^T y / s^T s$
<code>scalar2</code>	$\sigma = y^T y / s^T y$
<code>scalar3</code>	arithmetic average of <code>scalar1</code> and <code>scalar2</code>
<code>scalar4</code>	geometric average of <code>scalar1</code> and <code>scalar2</code>

limited_memory_init_val (*real*): Value for B_0 in low-rank update. [↩](#)

The starting matrix in the low rank update, B_0 , is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Default: 1

limited_memory_init_val_max (*real*): Upper bound on value for B_0 in low-rank update. [↩](#)

The starting matrix in the low rank update, B_0 , is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Default: `1e+08`

limited_memory_init_val_min (*real*): Lower bound on value for B_0 in low-rank update. [↩](#)

The starting matrix in the low rank update, B_0 , is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Default: `1e-08`

limited_memory_max_history (*integer*): Maximum size of the history for the limited quasi-Newton Hessian approximation. [↩](#)

This option determines the number of most recent iterations that are taken into account for the limited-memory quasi-Newton approximation.

Default: 6

limited_memory_max_skipping (*integer*): Threshold for successive iterations where update is skipped. [↩](#)

If the update is skipped more than this number of successive iterations, we quasi-Newton approximation is reset.

Range: $[1, \infty]$

Default: 2

limited_memory_special_for_resto (*string*): Determines if the quasi-Newton updates should be special during the restoration phase. [↔](#)

Until Nov 2010, Ipopt used a special update during the restoration phase, but it turned out that this does not work well. The new default uses the regular update procedure and it improves results. If for some reason you want to get back to the original update, set this option to "yes".

Default: no

value	meaning
no	use the same update as in regular iterations
yes	use the a special update during restoration phase

limited_memory_update_type (*string*): Quasi-Newton update formula for the limited memory approximation. [↔](#)

Determines which update formula is to be used for the limited-memory quasi-Newton approximation.

Default: bfgs

value	meaning
bfgs	BFGS update (with skipping)
sr1	SR1 (not working well)

linear_scaling_on_demand (*string*): Flag indicating that linear scaling is only done if it seems required. [↔](#)

This option is only important if a linear scaling method (e.g., mc19) is used. If you choose "no", then the scaling factors are computed for every linear system from the start. This can be quite expensive. Choosing "yes" means that the algorithm will start the scaling method only when the solutions to the linear system seem not good, and then use it until the end.

Default: yes

value	meaning
no	Always scale the linear system.
yes	Start using linear system scaling if solutions seem not good.

linear_solver (*string*): Linear solver used for step computations. [↔](#)

Determines which linear algebra package is to be used for the solution of the augmented linear system (for obtaining the search directions). Note, that MA27, MA57, MA86, and MA97 are only available with a commercially supported GAMS/IpoptH license, or when the user

provides a library with HSL code separately. If no GAMS/IpoptH license is available, the default linear solver is MUMPS. Pardiso is only available on Linux and Windows systems. For using Pardiso on non-Linux/Windows systems or MA77, a Pardiso or HSL library need to be provided.

Default: `ma27`

value	meaning
<code>ma27</code>	use the Harwell routine MA27
<code>ma57</code>	use the Harwell routine MA57
<code>ma77</code>	use the Harwell routine HSL_MA77
<code>ma86</code>	use the Harwell routine HSL_MA86
<code>ma97</code>	use the Harwell routine HSL_MA97
<code>mumps</code>	use MUMPS package
<code>pardiso</code>	use the Pardiso package

linear_system_scaling (*string*): Method for scaling the linear system. ↩

Determines the method used to compute symmetric scaling factors for the augmented system (see also the "linear_scaling_on_demand" option). This scaling is independent of the NLP problem scaling. By default, MC19 is only used if MA27 or MA57 are selected as linear solvers. Note, that MC19 is only available with a commercially supported GAMS/IpoptH license, or when the user provides a library with HSL code separately. If no commercial GAMS/IpoptH license is available, the default scaling method is slack-based.

Default: `mc19`

value	meaning
<code>mc19</code>	use the Harwell routine MC19
<code>none</code>	no scaling will be performed
<code>slack-based</code>	use the slack values

line_search_method (*string*): Globalization method used in backtracking line search ↩

Only the "filter" choice is officially supported. But sometimes, good results might be obtained with the other choices.

Default: `filter`

value	meaning
<code>cg-penalty</code>	Chen-Goldfarb penalty function
<code>filter</code>	Filter method
<code>penalty</code>	Standard penalty function

ma27_ignore_singularity (*string*): Enables MA27's ability to solve a linear system even if the matrix is singular. ↩

Setting this option to "yes" means that Ipopt will call MA27 to compute solutions for right hand sides, even if MA27 has detected that the matrix is singular (but is still able to solve the linear system). In some cases this might be better than using Ipopt's heuristic of small perturbation of the lower diagonal of the KKT matrix.

Default: `no`

value	meaning
no	Don't have MA27 solve singular systems
yes	Have MA27 solve singular systems

ma27_la_init_factor (*real*): Real workspace memory for MA27. [↔](#)

The initial real workspace memory = `la_init_factor` * memory required by unfactored system. Ipopt will increase the workspace size by `meminc_factor` if required. This option is only available if Ipopt has been compiled with MA27.

Range: $[1, \infty]$

Default: 5

ma27_liw_init_factor (*real*): Integer workspace memory for MA27. [↔](#)

The initial integer workspace memory = `liw_init_factor` * memory required by unfactored system. Ipopt will increase the workspace size by `meminc_factor` if required. This option is only available if Ipopt has been compiled with MA27.

Range: $[1, \infty]$

Default: 5

ma27_meminc_factor (*real*): Increment factor for workspace size for MA27. [↔](#)

If the integer or real workspace is not large enough, Ipopt will increase its size by this factor. This option is only available if Ipopt has been compiled with MA27.

Range: $[1, \infty]$

Default: 2

ma27_pivtol (*real*): Pivot tolerance for the linear solver MA27. [↔](#)

A smaller number pivots for sparsity, a larger number pivots for stability. This option is only available if Ipopt has been compiled with MA27.

Range: $[0, 1]$

Default: 1e-08

ma27_pivtolmax (*real*): Maximum pivot tolerance for the linear solver MA27. [↔](#)

Ipopt may increase `pivtol` as high as `pivtolmax` to get a more accurate solution to the linear system. This option is only available if Ipopt has been compiled with MA27.

Range: $[0, 1]$

Default: 0.0001

ma27_skip_inertia_check (*string*): Always pretend inertia is correct. [↔](#)

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Default: no

value	meaning
no	check inertia
yes	skip inertia check

ma28_pivtol (*real*): Pivot tolerance for linear solver MA28. [↔](#)

This is used when MA28 tries to find the dependent constraints.

Range: [0, 1]

Default: 0.01

ma57_automatic_scaling (*string*): Controls MA57 automatic scaling [↔](#)

This option controls the internal scaling option of MA57. For higher reliability of the MA57 solver, you may want to set this option to yes. This is ICNTL(15) in MA57.

Default: no

value	meaning
no	Do not scale the linear system matrix
yes	Scale the linear system matrix

ma57_block_size (*integer*): Controls block size used by Level 3 BLAS in MA57BD [↔](#)

This is ICNTL(11) in MA57.

Range: [1, ∞]

Default: 16

ma57_node_amalgamation (*integer*): Node amalgamation parameter [↔](#)

This is ICNTL(12) in MA57.

Range: [1, ∞]

Default: 16

ma57_pivot_order (*integer*): Controls pivot order in MA57 [↔](#)

This is ICNTL(6) in MA57.

Range: [0, 5]

Default: 5

ma57_pivtol (*real*): Pivot tolerance for the linear solver MA57. [↔](#)

A smaller number pivots for sparsity, a larger number pivots for stability. This option is only available if Ipopt has been compiled with MA57.

Range: [0, 1]

Default: 1e-08

ma57_pivtolmax (*real*): Maximum pivot tolerance for the linear solver MA57. [↔](#)

Ipopt may increase pivtol as high as ma57_pivtolmax to get a more accurate solution to the linear system. This option is only available if Ipopt has been compiled with MA57.

Range: $[0, 1]$

Default: 0.0001

ma57_pre_alloc (*real*): Safety factor for work space memory allocation for the linear solver MA57. [↔](#)

If 1 is chosen, the suggested amount of work space is used. However, choosing a larger number might avoid reallocation if the suggest values do not suffice. This option is only available if Ipopt has been compiled with MA57.

Range: $[1, \infty]$

Default: 1.05

ma57_small_pivot_flag (*integer*): If set to 1, then when small entries defined by CNTL(2) are detected they are removed and the corresponding pivots placed at the end of the factorization. This can be particularly efficient if the matrix is highly rank deficient. [↔](#)

This is ICNTL(16) in MA57.

Range: $[0, 1]$

Default: 0

ma77_buffer_lpage (*integer*): Number of scalars per MA77 buffer page [↔](#)

Number of scalars per an in-core buffer in the out-of-core solver MA77. Must be at most ma77_file_size.

Range: $[1, \infty]$

Default: 4096

ma77_buffer_npage (*integer*): Number of pages that make up MA77 buffer [↔](#)

Number of pages of size buffer_lpage that exist in-core for the out-of-core solver MA77.

Range: $[1, \infty]$

Default: 1600

ma77_file_size (*integer*): Target size of each temporary file for MA77, scalars per type [↔](#)

MA77 uses many temporary files, this option controls the size of each one. It is measured in the number of entries (int or double), NOT bytes.

Range: $[1, \infty]$

Default: 2097152

ma77_maxstore (*integer*): Maximum storage size for MA77 in-core mode [↔](#)

If greater than zero, the maximum size of factors stored in core before out-of-core mode is invoked.

Default: 0

ma77_nemin (*integer*): Node Amalgamation parameter [↔](#)

Two nodes in elimination tree are merged if result has fewer than ma77_nemin variables.

Range: $[1, \infty]$

Default: 8

ma77_order (*string*): Controls type of ordering used by HSL_MA77 [↔](#)

This option controls ordering for the solver HSL_MA77.

Default: `metis`

value	meaning
amd	Use the HSL_MC68 approximate minimum degree algorithm
metis	Use the MeTiS nested dissection algorithm (if available)

ma77_print_level (*integer*): Debug printing level for the linear solver MA77 [↔](#)

Range: $[-\infty, \infty]$

Default: -1

ma77_small (*real*): Zero Pivot Threshold [↔](#)

Any pivot less than `ma77_small` is treated as zero.

Default: 1e-20

ma77_static (*real*): Static Pivoting Threshold [↔](#)

See MA77 documentation. Either `ma77_static=0.0` or `ma77_static>ma77_small`.
`ma77_static=0.0` disables static pivoting.

Default: 0

ma77_u (*real*): Pivoting Threshold [↔](#)

See MA77 documentation.

Range: $[0, 0.5]$

Default: 1e-08

ma77_umax (*real*): Maximum Pivoting Threshold [↔](#)

Maximum value to which `u` will be increased to improve quality.

Range: $[0, 0.5]$

Default: 0.0001

ma86_nemin (*integer*): Node Amalgamation parameter [↔](#)

Two nodes in elimination tree are merged if result has fewer than `ma86_nemin` variables.

Range: $[1, \infty]$

Default: 32

ma86_order (*string*): Controls type of ordering used by HSL_MA86 [↔](#)

This option controls ordering for the solver HSL_MA86.

Default: `auto`

value	meaning
amd	Use the HSL_MC68 approximate minimum degree algorithm
auto	Try both AMD and MeTiS, pick best
metis	Use the MeTiS nested dissection algorithm (if available)

ma86_print_level (*integer*): Debug printing level for the linear solver MA86 [↔](#)

Range: $[-\infty, \infty]$

Default: -1

ma86_scaling (*string*): Controls scaling of matrix [↔](#)

This option controls scaling for the solver HSL_MA86.

Default: mc64

value	meaning
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]
none	Do not scale the linear system matrix

ma86_small (*real*): Zero Pivot Threshold [↔](#)

Any pivot less than ma86_small is treated as zero.

Default: 1e-20

ma86_static (*real*): Static Pivoting Threshold [↔](#)

See MA86 documentation. Either `ma86_static=0.0` or `ma86_static>ma86_small`. `ma86_static=0.0` disables static pivoting.

Default: 0

ma86_u (*real*): Pivoting Threshold [↔](#)

See MA86 documentation.

Range: $[0, 0.5]$

Default: 1e-08

ma86_umax (*real*): Maximum Pivoting Threshold [↔](#)

Maximum value to which u will be increased to improve quality.

Range: $[0, 0.5]$

Default: 0.0001

ma97_nemin (*integer*): Node Amalgamation parameter [↔](#)

Two nodes in elimination tree are merged if result has fewer than ma97_nemin variables.

Range: $[1, \infty]$

Default: 8

ma97_order (*string*): Controls type of ordering used by HSL_MA97 [↔](#)

Default: auto

value	meaning
amd	Use the HSL_MC68 approximate minimum degree algorithm
auto	Use HSL_MA97 heuristic to guess best of AMD and METIS
best	Try both AMD and MeTiS, pick best
matched-amd	Use the HSL_MC80 matching based ordering with AMD
matched-auto	Use the HSL_MC80 matching with heuristic choice of AMD or METIS
matched-metis	Use the HSL_MC80 matching based ordering with METIS
metis	Use the MeTiS nested dissection algorithm

ma97_print_level (*integer*): Debug printing level for the linear solver MA97 [↔](#)

Range: $[-\infty, \infty]$

Default: 0

ma97_scaling (*string*): Specifies strategy for scaling in HSL_MA97 linear solver [↔](#)

Default: `dynamic`

value	meaning
dynamic	Dynamically select scaling according to rules specified by <code>ma97_scalingX</code> and <code>ma97_switchX</code> options.
mc30	Scale all linear system matrices using MC30
mc64	Scale all linear system matrices using MC64
mc77	Scale all linear system matrices using MC77 [1,3,0]
none	Do not scale the linear system matrix

ma97_scaling1 (*string*): First scaling. [↔](#)

If `ma97_scaling=dynamic`, this scaling is used according to the trigger `ma97_switch1`. If `ma97_switch2` is triggered it is disabled.

Default: `mc64`

value	meaning
mc30	Scale linear system matrix using MC30
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]
none	No scaling

ma97_scaling2 (*string*): Second scaling. [↔](#)

If `ma97_scaling=dynamic`, this scaling is used according to the trigger `ma97_switch2`. If `ma97_switch3` is triggered it is disabled.

Default: `mc64`

value	meaning
mc30	Scale linear system matrix using MC30
mc64	Scale linear system matrix using MC64

value	meaning
mc77	Scale linear system matrix using MC77 [1,3,0]
none	No scaling

ma97_scaling3 (*string*): Third scaling. ↔

If ma97_scaling=dynamic, this scaling is used according to the trigger ma97_switch3.

Default: mc64

value	meaning
mc30	Scale linear system matrix using MC30
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]
none	No scaling

ma97_small (*real*): Zero Pivot Threshold ↔

Any pivot less than ma97_small is treated as zero.

Default: 1e-20

ma97_solve_blas3 (*string*): Controls if blas2 or blas3 routines are used for solve ↔

Default: no

value	meaning
no	Use BLAS2 (faster, some implementations bit incompatible)
yes	Use BLAS3 (slower)

ma97_switch1 (*string*): First switch, determine when ma97_scaling1 is enabled. ↔

If ma97_scaling=dynamic, ma97_scaling1 is enabled according to this condition. If ma97_switch2 occurs this option is henceforth ignored.

Default: od_hd_reuse

value	meaning
at_start	Scaling to be used from the very start.
at_start_reuse	Scaling to be used on first iteration, then reused thereafter.
high_delay	Scaling to be used after more than 0.05*n delays are present
high_delay_reuse	Scaling to be used only when previous itr created more that 0.05*n additional delays, otherwise reuse scaling from previous itr
never	Scaling is never enabled.
od_hd	Combination of on_demand and high_delay
od_hd_reuse	Combination of on_demand_reuse and high_delay_reuse
on_demand	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
on_demand_reuse	As on_demand, but reuse scaling from previous itr

ma97_switch2 (*string*): Second switch, determine when ma97_scaling2 is enabled. ↩

If ma97_scaling=dynamic, ma97_scaling2 is enabled according to this condition. If ma97_switch3 occurs this option is henceforth ignored.

Default: `never`

value	meaning
<code>at_start</code>	Scaling to be used from the very start.
<code>at_start_reuse</code>	Scaling to be used on first iteration, then reused thereafter.
<code>high_delay</code>	Scaling to be used after more than $0.05 \cdot n$ delays are present
<code>high_delay_reuse</code>	Scaling to be used only when previous itr created more than $0.05 \cdot n$ additional delays, otherwise reuse scaling from previous itr
<code>never</code>	Scaling is never enabled.
<code>od_hd</code>	Combination of <code>on_demand</code> and <code>high_delay</code>
<code>od_hd_reuse</code>	Combination of <code>on_demand_reuse</code> and <code>high_delay_reuse</code>
<code>on_demand</code>	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
<code>on_demand_reuse</code>	As <code>on_demand</code> , but reuse scaling from previous itr

ma97_switch3 (*string*): Third switch, determine when ma97_scaling3 is enabled. ↩

If ma97_scaling=dynamic, ma97_scaling3 is enabled according to this condition.

Default: `never`

value	meaning
<code>at_start</code>	Scaling to be used from the very start.
<code>at_start_reuse</code>	Scaling to be used on first iteration, then reused thereafter.
<code>high_delay</code>	Scaling to be used after more than $0.05 \cdot n$ delays are present
<code>high_delay_reuse</code>	Scaling to be used only when previous itr created more than $0.05 \cdot n$ additional delays, otherwise reuse scaling from previous itr
<code>never</code>	Scaling is never enabled.
<code>od_hd</code>	Combination of <code>on_demand</code> and <code>high_delay</code>
<code>od_hd_reuse</code>	Combination of <code>on_demand_reuse</code> and <code>high_delay_reuse</code>
<code>on_demand</code>	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
<code>on_demand_reuse</code>	As <code>on_demand</code> , but reuse scaling from previous itr

ma97_u (*real*): Pivoting Threshold ↩

See MA97 documentation.

Range: $[0, 0.5]$

Default: `1e-08`

ma97_umax (*real*): Maximum Pivoting Threshold ↩

See MA97 documentation.

Range: $[0, 0.5]$

Default: `0.0001`

max_cpu_time (*real*): Maximum number of CPU seconds. [↔](#)

A limit on CPU seconds that Ipopt can use to solve one problem. If during the convergence check this limit is exceeded, Ipopt will terminate with a corresponding error message.

Default: 1000

max_filter_resets (*integer*): Maximal allowed number of filter resets [↔](#)

A positive number enables a heuristic that resets the filter, whenever in more than "filter_reset_trigger" successive iterations the last rejected trial steps size was rejected because of the filter. This option determine the maximal number of resets that are allowed to take place.

Default: 5

max_hessian_perturbation (*real*): Maximum value of regularization parameter for handling negative curvature. [↔](#)

In order to guarantee that the search directions are indeed proper descent directions, Ipopt requires that the inertia of the (augmented) linear system for the step computation has the correct number of negative and positive eigenvalues. The idea is that this guides the algorithm away from maximizers and makes Ipopt more likely converge to first order optimal points that are minimizers. If the inertia is not correct, a multiple of the identity matrix is added to the Hessian of the Lagrangian in the augmented system. This parameter gives the maximum value of the regularization parameter. If a regularization of that size is not enough, the algorithm skips this iteration and goes to the restoration phase. (This is $\delta w^{\max}$ in the implementation paper.)

Default: $1e+20$

max_iter (*integer*): Maximum number of iterations. [↔](#)

The algorithm terminates with an error message if the number of iterations exceeded this number.

Default: `maxint`

max_refinement_steps (*integer*): Maximum number of iterative refinement steps per linear system solve. [↔](#)

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the maximum number of iterative refinement steps.

Default: 10

max_resto_iter (*integer*): Maximum number of successive iterations in restoration phase. [↔](#)

The algorithm terminates with an error message if the number of iterations successively taken in the restoration phase exceeds this number.

Default: 3000000

max_soc (*integer*): Maximum number of second order correction trial steps at each iteration. [↔](#)

Choosing 0 disables the second order corrections. (This is $p^{\max}$ of Step A-5.9 of Algorithm A in the implementation paper.)

Default: 4

max_soft_resto_iters (*integer*): Maximum number of iterations performed successively in soft restoration phase. [↔](#)

If the soft restoration phase is performed for more than so many iterations in a row, the regular restoration phase is called.

Default: 10

mehrotra_algorithm (*string*): Indicates if we want to do Mehrotra's algorithm. [↔](#)

If set to yes, Ipopt runs as Mehrotra's predictor-corrector algorithm. This works usually very well for LPs and convex QPs. This automatically disables the line search, and chooses the (unglobalized) adaptive mu strategy with the "probing" oracle, and uses "corrector_type=affine" without any safeguards; you should not set any of those options explicitly in addition. Also, unless otherwise specified, the values of "bound_push", "bound_frac", and "bound_mult_init_val" are set more aggressive, and sets "alpha_for_y=bound_mult".

Default: no

value	meaning
no	Do the usual Ipopt algorithm.
yes	Do Mehrotra's predictor-corrector algorithm.

min_hessian_perturbation (*real*): Smallest perturbation of the Hessian block. [↔](#)

The size of the perturbation of the Hessian block is never selected smaller than this value, unless no perturbation is necessary. (This is $\delta_w^{\min}$ in implementation paper.)

Default: 1e-20

min_refinement_steps (*integer*): Minimum number of iterative refinement steps per linear system solve. [↔](#)

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the minimum number of iterative refinements (i.e. at least "min_refinement_steps" iterative refinement steps are enforced per right hand side.)

Default: 1

mumps_dep_tol (*real*): Pivot threshold for detection of linearly dependent constraints in MUMPS. [↔](#)

When MUMPS is used to determine linearly dependent constraints, this determines the threshold for a pivot to be considered zero. This is CNTL(3) in MUMPS.

Range: $[-\infty, \infty]$

Default: 0

mumps_mem_percent (*integer*): Percentage increase in the estimated working space for MUMPS. [↔](#)

In MUMPS when significant extra fill-in is caused by numerical pivoting, larger values of mumps_mem_percent may help use the workspace more efficiently. On the other hand, if memory requirements are too large at the very beginning of the optimization, choosing a much smaller value for this option, such as 5, might reduce memory requirements.

Default: 1000

mumps_permuting_scaling (*integer*): Controls permuting and scaling in MUMPS [↔](#)

This is ICNTL(6) in MUMPS.

Range: [0, 7]

Default: 7

mumps_pivot_order (*integer*): Controls pivot order in MUMPS [↔](#)

This is ICNTL(7) in MUMPS.

Range: [0, 7]

Default: 7

mumps_pivtol (*real*): Pivot tolerance for the linear solver MUMPS. [↔](#)

A smaller number pivots for sparsity, a larger number pivots for stability. This option is only available if Ipopt has been compiled with MUMPS.

Range: [0, 1]

Default: 1e-06

mumps_pivtolmax (*real*): Maximum pivot tolerance for the linear solver MUMPS. [↔](#)

Ipopt may increase pivtol as high as pivtolmax to get a more accurate solution to the linear system. This option is only available if Ipopt has been compiled with MUMPS.

Range: [0, 1]

Default: 0.1

mumps_scaling (*integer*): Controls scaling in MUMPS [↔](#)

This is ICNTL(8) in MUMPS.

Range: [-2, 77]

Default: 77

mu_allow_fast_monotone_decrease (*string*): Allow skipping of barrier problem if barrier test is already met. [↔](#)

If set to "no", the algorithm enforces at least one iteration per barrier problem, even if the barrier test is already met for the updated barrier parameter.

Default: yes

value	meaning
no	Take at least one iteration per barrier problem
yes	Allow fast decrease of mu if barrier test it met

mu_init (*real*): Initial value for the barrier parameter. [↔](#)

This option determines the initial value for the barrier parameter (μ). It is only relevant in the monotone, Fiacco-McCormick version of the algorithm. (i.e., if "mu_strategy" is chosen as "monotone")

Default: 0.1

mu_linear_decrease_factor (*real*): Determines linear decrease rate of barrier parameter. [↔](#)

For the Fiacco-McCormick update procedure the new barrier parameter μ is obtained by taking the minimum of $\mu \cdot \text{mu\_linear\_decrease\_factor}$ and $\mu^{\text{superlinear\_decrease\_power}}$. (This is κ_μ in implementation paper.) This option is also used in the adaptive μ strategy during the monotone mode.

Range: [0, 1]

Default: 0.2

mu_max (*real*): Maximum value for barrier parameter. [↔](#)

This option specifies an upper bound on the barrier parameter in the adaptive μ selection mode. If this option is set, it overwrites the effect of mu_max_fact. (Only used if option "mu_strategy" is chosen as "adaptive".)

Default: 100000

mu_max_fact (*real*): Factor for initialization of maximum value for barrier parameter. [↔](#)

This option determines the upper bound on the barrier parameter. This upper bound is computed as the average complementarity at the initial point times the value of this option. (Only used if option "mu_strategy" is chosen as "adaptive".)

Default: 1000

mu_min (*real*): Minimum value for barrier parameter. [↔](#)

This option specifies the lower bound on the barrier parameter in the adaptive μ selection mode. By default, it is set to the minimum of $1e-11$ and $\min(\text{"tol"}, \text{"compl\_inf\_tol"}) / (\text{"barrier\_tol\_factor"} + 1)$, which should be a reasonable value. (Only used if option "mu_strategy" is chosen as "adaptive".)

Default: $1e-11$

mu_oracle (*string*): Oracle for a new barrier parameter in the adaptive strategy. [↔](#)

Determines how a new barrier parameter is computed in each "free-mode" iteration of the adaptive barrier parameter strategy. (Only considered if "adaptive" is selected for option "mu_strategy").

Default: quality-function

value	meaning
loqo	LOQO's centrality rule
probing	Mehrotra's probing heuristic
quality-function	minimize a quality function

mu_strategy (*string*): Update strategy for barrier parameter. [↔](#)

Determines which barrier parameter update strategy is to be used.

Default: **adaptive**

value	meaning
adaptive	use the adaptive update strategy
monotone	use the monotone (Fiacco-McCormick) strategy

mu_superlinear_decrease_power (*real*): Determines superlinear decrease rate of barrier parameter. [↔](#)

For the Fiacco-McCormick update procedure the new barrier parameter μ is obtained by taking the minimum of $\mu \cdot \text{mu\_linear\_decrease\_factor}$ and $\mu^{\text{mu\_superlinear\_decrease\_power}}$. (This is θ_μ in implementation paper.) This option is also used in the adaptive μ strategy during the monotone mode.

Range: [1, 2]

Default: 1.5

mu_target (*real*): Desired value of complementarity. [↔](#)

Usually, the barrier parameter is driven to zero and the termination test for complementarity is measured with respect to zero complementarity. However, in some cases it might be desired to have Ipopt solve barrier problem for strictly positive value of the barrier parameter. In this case, the value of "mu_target" specifies the final value of the barrier parameter, and the termination tests are then defined with respect to the barrier problem for this value of the barrier parameter.

Default: 0

neg_curv_test_reg (*string*): Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014). [↔](#)

Default: **yes**

value	meaning
no	use original IPOPT approach, in which the primal regularization is ignored
yes	use primal regularization with the inertia-free curvature test

neg_curv_test_tol (*real*): Tolerance for heuristic to ignore wrong inertia. [↔](#)

If nonzero, incorrect inertia in the augmented system is ignored, and Ipopt tests if the direction is a direction of positive curvature. This tolerance is α_n in the paper by Zavala and Chiang (2014) and it determines when the direction is considered to be sufficiently positive. A value in the range of [1e-12, 1e-11] is recommended.

Default: 0

nlp_scaling_constr_target_gradient (*real*): Target value for constraint function gradient size. [↔](#)

If a positive number is chosen, the scaling factor the constraint functions is computed so that the gradient has the max norm of the given size at the starting point. This overrides `nlp_scaling_max_gradient` for the constraint functions.

Default: 0

nlp_scaling_max_gradient (*real*): Maximum gradient after NLP scaling. [↔](#)

This is the gradient scaling cut-off. If the maximum gradient is above this value, then gradient based scaling will be performed. Scaling parameters are calculated to scale the maximum gradient back to this value. (This is `g_max` in Section 3.8 of the implementation paper.) Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Default: 100

nlp_scaling_method (*string*): Select the technique used for scaling the NLP. [↔](#)

Selects the technique used for scaling the problem internally before it is solved. For user-scaling, the parameters come from the NLP. If you are using AMPL, they can be specified through suffixes ("scaling_factor")

Default: `gradient-based`

value	meaning
<code>equilibration-based</code>	scale the problem so that first derivatives are of order 1 at random points (only available with MC19)
<code>gradient-based</code>	scale the problem so the maximum gradient at the starting point is <code>scaling_max_gradient</code>
<code>none</code>	no problem scaling will be performed

nlp_scaling_min_value (*real*): Minimum value of gradient-based scaling values. [↔](#)

This is the lower bound for the scaling factors computed by gradient-based scaling method. If some derivatives of some functions are huge, the scaling factors will otherwise become very small, and the (unscaled) final constraint violation, for example, might then be significant. Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Default: `1e-08`

nlp_scaling_obj_target_gradient (*real*): Target value for objective function gradient size. [↔](#)

If a positive number is chosen, the scaling factor the objective function is computed so that the gradient has the max norm of the given size at the starting point. This overrides `nlp_scaling_max_gradient` for the objective function.

Default: 0

nu_inc (*real*): Increment of the penalty parameter. [↔](#)

Default: 0.0001

nu_init (*real*): Initial value of the penalty parameter. [↔](#)

Default: `1e-06`

obj_max_inc (*real*): Determines the upper bound on the acceptable increase of barrier objective function. [↔](#)

Trial points are rejected if they lead to an increase in the barrier objective function by more than `obj_max_inc` orders of magnitude.

Range: $[1, \infty]$

Default: 5

pardiso_matching_strategy (*string*): Matching strategy to be used by Pardiso [↔](#)

This is IPAR(13) in Pardiso manual.

Default: `complete+2x2`

value	meaning
complete	Match complete (IPAR(13)=1)
complete+2x2	Match complete+2x2 (IPAR(13)=2)
constraints	Match constraints (IPAR(13)=3)

pardiso_max_iterative_refinement_steps (*integer*): Limit on number of iterative refinement steps. [↔](#)

The solver does not perform more than the absolute value of this value steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. If negative, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement. The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and this option is set to 0.

Range: $[-\infty, \infty]$

Default: 1

pardiso_msglvl (*integer*): Pardiso message level [↔](#)

This determines the amount of analysis output from the Pardiso solver. This is MSGVLV in the Pardiso manual.

Default: 0

pardiso_order (*string*): Controls the fill-in reduction ordering algorithm for the input matrix. [↔](#)

Default: metis

value	meaning
amd	minimum degree algorithm
metis	MeTiS nested dissection algorithm
one	undocumented
pmetis	parallel (OpenMP) version of MeTiS nested dissection algorithm

pardiso_redo_symbolic_fact_only_if_inertia_wrong (*string*): Toggle for handling case when elements were perturbed by Pardiso. [↔](#)

Default: no

value	meaning
no	Always redo symbolic factorization when elements were perturbed
yes	Only redo symbolic factorization when elements were perturbed if also the inertia was wrong

pardiso_repeated_perturbation_means_singular (*string*): Interpretation of perturbed elements. [↔](#)

Default: no

value	meaning
no	Don't assume that matrix is singular if elements were perturbed after recent symbolic factorization

value	meaning
yes	Assume that matrix is singular if elements were perturbed after recent symbolic factorization

pardiso_skip_inertia_check (*string*): Always pretend inertia is correct. [↔](#)

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Default: no

value	meaning
no	check inertia
yes	skip inertia check

perturb_always_cd (*string*): Active permanent perturbation of constraint linearization. [↔](#)

This options makes the delta_c and delta_d perturbation be used for the computation of every search direction. Usually, it is only used when the iteration matrix is singular.

Default: no

value	meaning
no	perturbation only used when required
yes	always use perturbation

perturb_dec_fact (*real*): Decrease factor for x-s perturbation. [↔](#)

The factor by which the perturbation is decreased when a trial value is deduced from the size of the most recent successful perturbation. (This is κ_w^- in the implementation paper.)

Range: [0, 1]

Default: 0.333333

perturb_inc_fact (*real*): Increase factor for x-s perturbation. [↔](#)

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of all perturbations except for the first. (This is κ_w^+ in the implementation paper.)

Range: [1, ∞]

Default: 8

perturb_inc_fact_first (*real*): Increase factor for x-s perturbation for very first perturbation. [↔](#)

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of the very first perturbation and allows a different value for for the first perturbation than that used for the remaining perturbations. (This is $\bar{\kappa}_w^+$ in the implementation paper.)

Range: [1, ∞]

Default: 100

print_eval_error (*string*): Switch to enable printing information about function evaluation errors into the GAMS listing file. [↔](#)

Default: **yes**

Values: **no**, **yes**

print_frequency_iter (*integer*): Determines at which iteration frequency the summarizing iteration output line should be printed. [↔](#)

Summarizing iteration output is printed every `print_frequency_iter` iterations, if at least `print_frequency_time` seconds have passed since last output.

Range: $[1, \infty]$

Default: **1**

print_frequency_time (*real*): Determines at which time frequency the summarizing iteration output line should be printed. [↔](#)

Summarizing iteration output is printed if at least `print_frequency_time` seconds have passed since last output and the iteration number is a multiple of `print_frequency_iter`.

Default: **0**

print_info_string (*string*): Enables printing of additional info string at end of iteration output. [↔](#)

This string contains some insider information about the current iteration. For details, look for "Diagnostic Tags" in the IpopT documentation.

Default: **no**

value	meaning
no	don't print string
yes	print string at end of each iteration output

print_level (*integer*): Output verbosity level. [↔](#)

Sets the default verbosity level for console output. The larger this value the more detailed is the output.

Range: $[0, 12]$

Default: **5**

print_timing_statistics (*string*): Switch to print timing statistics. [↔](#)

If selected, the program will print the CPU usage (user time) for selected tasks.

Default: **no**

value	meaning
no	don't print statistics
yes	print all timing statistics

quality_function_balancing_term (*string*): The balancing term included in the quality function for centrality. [↔](#)

This determines whether a term is added to the quality function that penalizes situations where the complementarity is much smaller than dual and primal infeasibilities. (Only used if option "mu_oracle" is set to "quality-function".)

Default: none

value	meaning
cubic	$\text{Max}(0, \text{Max}(\text{dual\_inf}, \text{primal\_inf}) - \text{compl})^3$
none	no balancing term is added

quality_function_centrality (*string*): The penalty term for centrality that is included in quality function. [↔](#)

This determines whether a term is added to the quality function to penalize deviation from centrality with respect to complementarity. The complementarity measure here is the xi in the Logo update rule. (Only used if option "mu_oracle" is set to "quality-function".)

Default: none

value	meaning
cubed-reciprocal	complementarity * the reciprocal of the centrality measure cubed
log	complementarity * the log of the centrality measure
none	no penalty term is added
reciprocal	complementarity * the reciprocal of the centrality measure

quality_function_max_section_steps (*integer*): Maximum number of search steps during direct search procedure determining the optimal centering parameter. [↔](#)

The golden section search is performed for the quality function based mu oracle. (Only used if option "mu_oracle" is set to "quality-function".)

Default: 8

quality_function_norm_type (*string*): Norm used for components of the quality function. [↔](#)

(Only used if option "mu_oracle" is set to "quality-function".)

Default: 2-norm-squared

value	meaning
1-norm	use the 1-norm (abs sum)
2-norm	use 2-norm
2-norm-squared	use the 2-norm squared (sum of squares)
max-norm	use the infinity norm (max)

quality_function_section_qf_tol (*real*): Tolerance for the golden section search procedure determining the optimal centering parameter (in the function value space). [↔](#)

The golden section search is performed for the quality function based mu oracle. (Only used if option "mu_oracle" is set to "quality-function".)

Range: [0, 1]

Default: 0

quality_function_section_sigma_tol (*real*): Tolerance for the section search procedure determining the optimal centering parameter (in sigma space). ↩

The golden section search is performed for the quality function based mu oracle. (Only used if option "mu_oracle" is set to "quality-function".)

Range: [0, 1]

Default: 0.01

recalc_y (*string*): Tells the algorithm to recalculate the equality and inequality multipliers as least square estimates. ↩

This asks the algorithm to recompute the multipliers, whenever the current infeasibility is less than `recalc_y_feas_tol`. Choosing yes might be helpful in the quasi-Newton option. However, each recalculation requires an extra factorization of the linear system. If a limited memory quasi-Newton option is chosen, this is used by default.

Default: no

value	meaning
no	use the Newton step to update the multipliers
yes	use least-square multiplier estimates

recalc_y_feas_tol (*real*): Feasibility threshold for recomputation of multipliers. ↩

If `recalc_y` is chosen and the current infeasibility is less than this value, then the multipliers are recomputed.

Default: 1e-06

replace_bounds (*string*): Indicates if all variable bounds should be replaced by inequality constraints ↩

This option must be set for the inexact algorithm

Default: no

value	meaning
no	leave bounds on variables
yes	replace variable bounds by inequality constraints

report_mininfeas_solution (*string*): Switch to report intermediate solution with minimal constraint violation to GAMS if the final solution is not feasible. ↩

This option allows to obtain the most feasible solution found by Ipopt during the iteration process, if it stops at a (locally) infeasible solution, due to a limit (time, iterations, ...), or with a failure in the restoration phase.

Default: no

Values: no, yes

required_infeasibility_reduction (*real*): Required reduction of infeasibility before leaving restoration phase. [↩](#)

The restoration phase algorithm is performed, until a point is found that is acceptable to the filter and the infeasibility has been reduced by at least the fraction given by this option.

Range: [0, 1]

Default: 0.9

residual_improvement_factor (*real*): Minimal required reduction of residual test ratio in iterative refinement. [↩](#)

If the improvement of the residual test ratio made by one iterative refinement step is not better than this factor, iterative refinement is aborted.

Default: 1

residual_ratio_max (*real*): Iterative refinement tolerance [↩](#)

Iterative refinement is performed until the residual test ratio is less than this tolerance (or until "max_refinement_steps" refinement steps are performed).

Default: 1e-10

residual_ratio_singular (*real*): Threshold for declaring linear system singular after failed iterative refinement. [↩](#)

If the residual test ratio is larger than this value after failed iterative refinement, the algorithm pretends that the linear system is singular.

Default: 1e-05

resto_failure_feasibility_threshold (*real*): Threshold for primal infeasibility to declare failure of restoration phase. [↩](#)

If the restoration phase is terminated because of the "acceptable" termination criteria and the primal infeasibility is smaller than this value, the restoration phase is declared to have failed. The default value is $1e2 \cdot \text{tol}$, where tol is the general termination tolerance.

Default: 0

resto_penalty_parameter (*real*): Penalty parameter in the restoration phase objective function. [↩](#)

This is the parameter ρ in equation (31a) in the Ipopt implementation paper.

Default: 1000

resto_proximity_weight (*real*): Weighting factor for the proximity term in restoration phase objective. [↩](#)

This determines how the parameter ζ in equation (29a) in the implementation paper is computed. ζ here is $\text{resto\_proximity\_weight} \cdot \sqrt{\mu}$, where μ is the current barrier parameter.

Default: 1

rho (*real*): Value in penalty parameter update formula. [↔](#)

Range: [0, 1]

Default: 0.1

sigma_max (*real*): Maximum value of the centering parameter. [↔](#)

This is the upper bound for the centering parameter chosen by the quality function based barrier parameter update. (Only used if option "mu_oracle" is set to "quality-function".)

Default: 100

sigma_min (*real*): Minimum value of the centering parameter. [↔](#)

This is the lower bound for the centering parameter chosen by the quality function based barrier parameter update. (Only used if option "mu_oracle" is set to "quality-function".)

Default: 1e-06

skip_corr_if_neg_curv (*string*): Skip the corrector step in negative curvature iteration. [↔](#)

The corrector step is not tried if negative curvature has been encountered during the computation of the search direction in the current iteration. This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Default: yes

value	meaning
no	don't skip
yes	skip

skip_corr_in_monotone_mode (*string*): Skip the corrector step during monotone barrier parameter mode. [↔](#)

The corrector step is not tried if the algorithm is currently in the monotone mode (see also option "barrier_strategy"). This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Default: yes

value	meaning
no	don't skip
yes	skip

slack_bound_frac (*real*): Desired minimum relative distance from the initial slack to bound. [↔](#)

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_push"). (This is kappa_2 in Section 3.6 of implementation paper.)

Range: [0, 0.5]

Default: 0.01

slack_bound_push (*real*): Desired minimum absolute distance from the initial slack to bound. [↔](#)

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_frac"). (This is κ_1 in Section 3.6 of implementation paper.)

Default: 0.01

slack_move (*real*): Correction size for very small slacks. [↔](#)

Due to numerical issues or the lack of an interior, the slack variables might become very small. If a slack becomes very small compared to machine precision, the corresponding bound is moved slightly. This parameter determines how large the move should be. Its default value is $\text{mach\_eps}^{\{3/4\}}$. (See also end of Section 3.5 in implementation paper - but actual implementation might be somewhat different.)

Default: 1.81899e-12

soc_method (*integer*): Ways to apply second order correction [↔](#)

This option determines the way to apply second order correction, 0 is the method described in the implementation paper. 1 is the modified way which adds alpha on the rhs of x and s rows.

Range: [0, 1]

Default: 0

soft_resto_pderror_reduction_factor (*real*): Required reduction in primal-dual error in the soft restoration phase. [↔](#)

The soft restoration phase attempts to reduce the primal-dual error with regular steps. If the damped primal-dual step (damped only to satisfy the fraction-to-the-boundary rule) is not decreasing the primal-dual error by at least this factor, then the regular restoration phase is called. Choosing "0" here disables the soft restoration phase.

Default: 0.9999

start_with_resto (*string*): Tells algorithm to switch to restoration phase in first iteration. [↔](#)

Setting this option to "yes" forces the algorithm to switch to the feasibility restoration phase in the first iteration. If the initial point is feasible, the algorithm will abort with a failure.

Default: no

value	meaning
no	don't force start in restoration phase
yes	force start in restoration phase

s_max (*real*): Scaling threshold for the NLP error. [↔](#)

(See paragraph after Eqn. (6) in the implementation paper.)

Default: 100

s_phi (*real*): Exponent for linear barrier function model in the switching rule. [↔](#)

(See Eqn. (19) in the implementation paper.)

Range: $[1, \infty]$

Default: 2.3

s_theta (*real*): Exponent for current constraint violation in the switching rule. [↩](#)

(See Eqn. (19) in the implementation paper.)

Range: $[1, \infty]$

Default: 1.1

tau_min (*real*): Lower bound on fraction-to-the-boundary parameter tau. [↩](#)

(This is tau_min in the implementation paper.) This option is also used in the adaptive mu strategy during the monotone mode.

Range: $[0, 1]$

Default: 0.99

theta_max_fact (*real*): Determines upper bound for constraint violation in the filter. [↩](#)

The algorithmic parameter theta_max is determined as theta_max_fact times the maximum of 1 and the constraint violation at initial point. Any point with a constraint violation larger than theta_max is unacceptable to the filter (see Eqn. (21) in the implementation paper).

Default: 10000

theta_min_fact (*real*): Determines constraint violation threshold in the switching rule. [↩](#)

The algorithmic parameter theta_min is determined as theta_min_fact times the maximum of 1 and the constraint violation at initial point. The switching rules treats an iteration as an h-type iteration whenever the current constraint violation is larger than theta_min (see paragraph before Eqn. (19) in the implementation paper).

Default: 0.0001

tiny_step_tol (*real*): Tolerance for detecting numerically insignificant steps. [↩](#)

If the search direction in the primal variables (x and s) is, in relative terms for each component, less than this value, the algorithm accepts the full step without line search. If this happens repeatedly, the algorithm will terminate with a corresponding exit message. The default value is 10 times machine precision.

Default: 2.22045e-15

tiny_step_y_tol (*real*): Tolerance for quitting because of numerically insignificant steps. [↩](#)

If the search direction in the primal variables (x and s) is, in relative terms for each component, repeatedly less than tiny_step_tol, and the step in the y variables is smaller than this threshold, the algorithm will terminate.

Default: 0.01

tol (*real*): Desired convergence tolerance (relative). [↩](#)

Determines the convergence tolerance for the algorithm. The algorithm terminates successfully, if the (scaled) NLP error becomes smaller than this value, and if the (absolute) criteria according to "dual_inf_tol", "constr_viol_tol", and "compl_inf_tol" are met. (This is epsilon_tol in Eqn. (6) in implementation paper). See also "acceptable_tol" as a second termination criterion. Note, some other algorithmic features also use this quantity to determine thresholds etc.

Default: 1e-08

warm_start_bound_frac (*real*): same as bound_frac for the regular initializer. [↔](#)

Range: [0, 0.5]

Default: 0.001

warm_start_bound_push (*real*): same as bound_push for the regular initializer. [↔](#)

Default: 0.001

warm_start_init_point (*string*): Warm-start for initial point [↔](#)

Indicates whether this optimization should use a warm start initialization, where values of primal and dual variables are given (e.g., from a previous optimization of a related problem.)

Default: no

value	meaning
no	do not use the warm start initialization
yes	use the warm start initialization

warm_start_mult_bound_push (*real*): same as mult_bound_push for the regular initializer. [↔](#)

Default: 0.001

warm_start_mult_init_max (*real*): Maximum initial value for the equality multipliers. [↔](#)

Range: $[-\infty, \infty]$

Default: 1e+06

warm_start_slack_bound_frac (*real*): same as slack_bound_frac for the regular initializer. [↔](#)

Range: [0, 0.5]

Default: 0.001

warm_start_slack_bound_push (*real*): same as slack_bound_push for the regular initializer. [↔](#)

Default: 0.001

watchdog_shortened_iter_trigger (*integer*): Number of shortened iterations that trigger the watchdog. [↔](#)

If the number of successive iterations in which the backtracking line search did not accept the first trial point exceeds this number, the watchdog procedure is activated. Choosing "0" here disables the watchdog procedure.

Default: 10

watchdog_trial_iter_max (*integer*): Maximum number of watchdog iterations. [↔](#)

This option determines the number of trial iterations allowed before the watchdog procedure is aborted and the algorithm returns to the stored point.

Range: [1, ∞]

Default: 3

5.25 JAMS and LogMIP

5.25.1 Introduction

EMP (Extended Mathematical Programming) is not a solver but an (experimental) framework for automated mathematical programming reformulations. The idea behind EMP is that new upcoming types of models which currently cannot be solved reliably are reformulated into models of established math programming classes in order to use mature solver technology. At this stage, EMP supports the modeling of Bilevel Programs, Variational Inequalities, Disjunctive Programs, Extended Nonlinear Programs and Embedded Complementarity Systems.

Extended mathematical programs are collections of functions and variables joined together using specific optimization and complementarity primitives. EMP annotates the existing relationships within a model to facilitate higher level structure identification. A specific implementation of this framework is outlined that reformulates the original GAMS model automatically using directives contained in an "empinfo" file into an equivalent model that can be solved using existing GAMS solvers.

The reformulation is done by the solver JAMS which currently is the only solver that is capable of handling EMP models. Examples showing how to use the EMP framework and the solver JAMS are made available through the GAMS EMP Library which is included in the GAMS Distribution. In order to generate a copy of an EMPLIB model, one can use the library facility of the GAMS IDE, or execute the command line directive `emplib <modelname>`, where `modelname` is the (stem of the) file containing the model.

EMP has been developed jointly by Michael Ferris of UW-Madison, Ignacio Grossmann of Carnegie Mellon University, and GAMS Development Corporation. EMP and JAMS come free of charge with any licensed GAMS system but require a subsolver to solve the generated models.

5.25.2 JAMS: a reformulation tool

EMP models are currently processed by the JAMS solver. The solver JAMS creates a scalar version of the given GAMS model. This scalar version of the model is then solved by an appropriate subsolver. By default, there are no reformulations carried out, so the model generated is simply a GAMS scalar form of the model the actual subsolver will process. The subsolver used is by default the currently specified solver for the given model type.

5.25.2.1 The JAMS Option File

As with any GAMS solver, JAMS has an option file, typically called `jams.opt`. A JAMS option [subsolver](#) is available to change the subsolver used for the reformulated model, along with an option to utilize a subsolver option file ([subsolveropt](#)).

The actual scalar version of the model can also be seen by the modeler using the option [filename](#). For example, the option file

```
subsolver path
subsolveropt 1
filename mcpmod.gms
```

when applied to an EMP model that is a complementarity problem will create a file called `mcpmod.gms` in the current directory and solve that model using the solver PATH utilizing any options for PATH that are specified in `path.opt`. The scalarized model is not particularly useful to look at since all of the original variables have been renamed into a scalar form. The mapping between original variables and the ones used in the scalar version of the model is given in a dictionary file that can also be seen by the modeler using the [dict option](#). If a user simply wants to generate this scalar model, then the option [terminate](#) will not solve the generated model.

After the scalar version of the model is solved, the solution values are mapped back into the original namespace and returned to the modeler as usual in the listing file. The JAMS option [margtol](#) allows the modeler to suppress reporting marginals that have (absolute) values smaller than this tolerance.

Obviously, all of the above functionality is not of much value: the key part of JAMS is to interpret additional directives to take the original model and produce a *reformulated* scalar model. This is carried out using an "empinfo" file. The syntax and use of this file is the content of the remaining sections of this document.

The option [EMPInfoFile](#) allows the user to specify the path and name of a file containing additional EMP information. The syntax of this file is described by examples elsewhere in this document and in section [Empinfo file details](#). There is a subtlety that should be mentioned when a user writes this file in the default location in the GAMS scratch directory of the current run specified in the gams file using:

```
file empinfo / '%emp.info%' /;
```

wherein certain additional formatting instructions are given. If instead, the file handle is given by:

```
file empinfo / 'empinfo.txt' /;
```

for example, then to produce the same file the following lines must be added to the gams source file:

```
empinfo.pc = 8;
empinfo.pw = 255;
```

The following tables list all available options.

5.25.2.2 Reformulation Options

Option	Description	Default
KeepObj	Keep original objective function and variables in generated MCP model. This option is only valid for reformulations into complementarity systems. If KeepObj is set the generated MCP program will incorporate the original objective function and the Karush-Kuhn-Tucker condition of the original objective variable.	0
MargTol	Only report marginals with an absolute value above the tolerance	1e-6
ObjVarName	Name of objective variable in generated model.	objvar

5.25.2.3 General Options

Option	Description	Default
CompModel	Complementarity model (MCP or VI) to generate for equilibrium problems.	mcp
Dict	Generate a dictionary file that maps original variable and equation names to the ones of the scalar JAMS model.	dict.txt
DisjBinRelax	Relax requirement that disjunction variables are binary.	0
EMPInfoFile	Path and name of file containing additional EMP information as disjunctions, perpendiculars, bilevel characterization etc. By default, the file is expected to exist in the GAMS scratch directory of the current run (<code>gams.scrdir</code>). If this option is used, EMP searches for the file based on the provided relative or absolute path. In case of a given relative path, it is assumed to be relative to the working directory.	
FileName	Filename of generated scalar reformulated GAMS model.	emp.gms
ImplVarModel	Reformulation model to generate for implicit variables. Replication: Shared variables are replicated for each agent Substitution: Shared multipliers are substituted out: assumes implicit function Switching: Switch function-variable matching to avoid replication	switching
NLConsToFunc	Stick nonlinear constraints into functional part when generating a VI model for equilibrium problems	0
SharedEqu	Allow shared equations in equilibrium problems	0
SubSolvePar	User defined GAMS parameters for subsolve	
SubSolver	Subsolver used to solve the reformulated model. The subsolver chosen has to be suitable for the chosen reformulation type. The user can also provide a solver related option file, see SubSolverOpt .	
SubSolverOpt	Optfile value to pass to the subsolver Range: [1, 999]	1
Terminate	Generate the GAMS source code of the reformulated model in a file and terminate without solving the model.	0
ZipDebug	Zip-file name to create if the internal GAMS model fails	none

5.25.3 Forming Optimality Conditions: NLP2MCP

The first nontrivial use of the JAMS solver is to automatically generate the first order conditions of a linear or nonlinear program; essentially we *reformulate* the optimization problem as a mixed complementarity problem (MCP). The "empinfo" file to do this simply contains the following line:

```
modeltype mcp
```

Behind the scenes, JAMS forms the Lagrangian of the nonlinear program and then forms its Karush-Kuhn-Tucker optimality conditions. To be clear, given the original nonlinear program

$$\min_x f(x) \text{ s.t. } g(x) \leq 0, h(x) = 0, \quad (\text{NLP})$$

the Lagrangian is:

$$\mathcal{L}(x, \lambda, \mu) = f(x) - \langle \lambda, g(x) \rangle - \langle \mu, h(x) \rangle.$$

The first order conditions are the following MCP:

$$\begin{array}{lll} 0 = \nabla_x \mathcal{L}(x, \lambda, \mu) & \perp & x \text{ free} \\ 0 \geq -\nabla_\lambda \mathcal{L}(x, \lambda, \mu) & \perp & \lambda \leq 0 \\ 0 = -\nabla_\mu \mathcal{L}(x, \lambda, \mu) & \perp & \mu \text{ free} \end{array}$$

A specific example is:

$$\begin{array}{ll} \min_{x,y,z} & -3x + y \\ \text{s.t.} & x + y \leq 1, \quad x + y - z = 2, \quad x, y \geq 0 \end{array}$$

which is found in the EMPLIB model **nlp2mcp**:

```
Positive Variables x, y;
Variables f, z;
Equations g, h, defobj;

g..      x + y      =l= 1;
h..      x + y - z  =e= 2;
defobj.. f          =e= -3*x + y;

model comp / defobj, g, h /;

file info / '%emp.info%' /;
putclose info / 'modeltype mcp';

solve comp using emp minimizing f;
```

The putclose line writes out the default "empinfo" file whose location is provided in the system string %emp.info%. Armed with this additional information, the EMP tool automatically creates the following MCP:

$$\begin{array}{lll} 0 \leq -3 - \lambda - \mu & \perp & x \geq 0 \\ 0 \leq 1 - \lambda - \mu & \perp & y \geq 0 \\ 0 = \mu & \perp & z \text{ free} \\ 0 \geq x + y - 1 & \perp & \lambda \leq 0 \\ 0 = x + y - z - 2 & \perp & \mu \text{ free.} \end{array}$$

5.25.4 Soft Constraints

In many cases, we wish to relax certain constraints in a model during solution (to help identify feasibility issues for example). As an example, consider the problem

$$\begin{array}{ll} \min_{x_1, x_2, x_3} & \exp(x_1) \\ \text{s.t.} & \log(x_1) = 1, \\ & x_2^2 \leq 2, \\ & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, \quad x_1 \geq 0, \quad x_2 \geq 0, \end{array}$$

which can be formulated in GAMS as

```
$title simple example of ENLP

Variables obj, x1, x2, x3;
Equations f0, f1, f2, f3, f4;

f0.. obj      =e= exp(x1);
f1.. log(x1)  =e= 1;
f2.. sqr(x2)  =g= 2;
f3.. x1/x2    =e= log(x3);
f4.. 3*x1 + x2 =l= 5;

x1.lo = 0; x2.lo = 0;

model enlpemp /all/;
x1.l = 1; x2.l = 1; x3.l = 1;
solve enlpemp using nlp min obj;
```

5.25.4.1 Reformulation as a classical NLP

Soft constraints allow us to treat certain equations in the model as "soft" by removing the constraints and adding a penalty term to the objective function. Explicitly, we replace the above problem by:

$$\begin{aligned} \min_{x_1, x_2, x_3} \quad & \exp(x_1) + 5 \|\log(x_1) - 1\|^2 + 2 \max(x_2^2 - 2, 0) \\ \text{s.t.} \quad & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0. \end{aligned}$$

In this problem, we still force $x_1/x_2 = \log(x_3)$, but apply a least squares penalty to $\log(x_1) - 1$ and a smaller one-sided penalization to $x_2^2 - 2$.

The above formulation is nonsmooth due to the "max" term in the objective function; in practice we would replace this by:

$$\begin{aligned} \min_{x_1, x_2, x_3, w} \quad & \exp(x_1) + 5 (\log(x_1) - 1)^2 + 2w \\ \text{s.t.} \quad & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0 \\ & w \geq x_2^2 - 2, w \geq 0 \end{aligned}$$

and recover a standard form NLP.

The "empinfo" file:

```
modeltype NLP
adjustequ
f1 sqr 5
f2 maxx 2
```

coupled with replacing the last line with

```
solve enlpemp using emp min obj;
```

achieves this goal. The parameter values provide the penalty coefficients above.

5.25.4.2 Reformulation as an MCP

As an alternative, we can rewrite the problem as an MCP, also dealing explicitly with the nonsmoothness. The "empinfo" file is given by:

```
modeltype NLP
adjustequ
f1 sqr 5
f2 maxx 2
```

and this generates the following MCP:

$$\begin{array}{ll} 0 = \log(x_1) - 1 + y_1/10 & \perp \quad y_1 \text{ free,} \\ 0 \leq x_2^2 - 2 & \perp \quad y_2 \geq 0, \\ 0 = x_1/x_2 - \log(x_3) & \perp \quad y_3 \text{ free,} \\ 0 \geq 3x_1 + x_2 - 5 & \perp \quad y_4 \leq 0, \\ 0 \leq \exp(x_1) - y_1/x_1 - y_3/x_2 - 3y_4 & \perp \quad x_1 \geq 0, \\ 0 \leq -2y_2x_2 + x_1y_3/x_2^2 - y_4 & \perp \quad x_2 \geq 0, \\ 0 = y_3/x_3 & \perp \quad x_3 \text{ free,} \end{array}$$

where y represent the multipliers.

A complete description of the process to derive this MCP will be given later in section [Extended Nonlinear Programs](#).

5.25.5 Bilevel Programs

Mathematical programs with optimization problems in their constraints have a long history in operations research including [28] [49] [100]. New codes are being developed that exploit this structure, at least for simple hierarchies, and attempt to define and implement algorithms for their solution.

The simplest case is that of bilevel programming, where an upper level problem depends on the solution of a lower level optimization. For example:

$$\begin{aligned} \min_{x,y} & f(x,y) \\ \text{s.t.} & g(x,y) \leq 0, \\ & y \text{ solves } \min_y v(x,y) \text{ s.t. } h(x,y) \geq 0. \end{aligned}$$

Often, the upper level is referred to as the "leader", while the lower level is the "follower".

This problem can be reformulated as a Mathematical Program with Complementarity Constraints (MPCC) by replacing the lower level optimization problem by its first order optimality conditions:

$$\begin{aligned} \min_{x,y} & f(x,y) \\ \text{s.t.} & g(x,y) \leq 0, \\ & 0 = \nabla_y v(x,y) - \lambda^T \nabla_y h(x,y) \perp x \text{ free} \\ & 0 \leq h(x,y) \perp \lambda \geq 0. \end{aligned}$$

We find a solution of the MPCC, not of the bilevel program. This approach allows the MPCC to be solved using the NLPEC code, for example. Note that this reformulation is potentially problematic. First order conditions require theoretical assumptions to be necessary and sufficient for *local optimality*. There may be cases where the lower level problem has multiple local solutions, but the modeler really was interested in the *global* solution. The approach here may not produce this solution, even if a global solver is used within NLPEC.

The following example is Example 5.1.1, page 197 from [28]. Mathematically, the problem is

$$\begin{aligned} \min_{x,y} & x - 4y \\ \text{s.t.} & y \text{ solves } \min_y y \\ & \text{s.t. } x + y \geq 3 \\ & 2x - y \geq 0 \\ & -2x - y \geq -12 \\ & -3x + 2y \geq -4 \end{aligned}$$

and the EMPLIB model **bard511** contains the following code:

```
Positive variables x, y;
Variables objout, objin;
equations defout, defin, e1, e2, e3, e4;

defout.. objout =e= x - 4*y;
defin..  objin  =e= y;

e1..    x +   y =g=  3;
e2..   2*x -   y =g=  0;
e3..  -2*x -   y =g= -12;
e4..  -3*x + 2*y =g= -4;

model bard / all /;

$echo bilevel x min objin y defin e1 e2 e3 e4 > "%emp.info%"

solve bard using emp minimizing objout;
```

Note that first the functions that form the objectives and constraints of the model are defined and the model is assembled. The `$echo` line writes the "empinfo" file and states that the lower level problem involves the objective `objin` which is to be minimized by choice of variables `y` subject to the constraints specified in (`defin`), `e1`, `e2`, `e3`, and `e4`.

Note that the variables x are declared to be variables of the upper level problem and this example has no upper level constraints g . Having written the problem in this way, the MPCC is generated automatically, and passed on to a solver. In the case where that solver is NLPEC, a further reformulation of the model is carried out to convert the MPCC into an equivalent NLP or a parametric sequence of NLP's.

Further examples of bilevel models in **EMPLIB** are named: `bard*`, `ccmg74`, `ccmg153`, `flds*`, `jointc1`, `jointc2`, `mirrlees`, `transbp`.

The EMP model type allows multiple lower level problems to be specified within the bilevel format. An example of this is given in EMPLIB as **ccmg71**. The equations and objectives are specified in the normal manner; the only change is the definition of the "empinfo" file, shown below:

```
...
defh1.. h1 =e= sqrt(u1-x1) + sqrt(u2-x2) + sqrt(u3-x3) + sqrt(u4-x4);
e1.. 3*u1 + u2 + 2*u3 + u4 =e= 6;
...
$onecho > "%emp.info%"
bilevel x1 x2 x3 x4
min h1 u1 u2 u3 u4 defh1 e1
min h2 v1 v2 v3 v4 defh2 e2
$offecho
```

This corresponds to a bilevel program with two followers, both solving minimization problems. The first follower minimizes the objective function `h1` (defined in `defh1`) over the variables `u1`, `u2`, `u3`, and `u4` subject to the constraint given in `e1`. The second followers problem is defined analogously next. Note that `h1` involves the variables `x1`, `x2`, `x3`, and `x4` that are optimization variables of the leader. The constraint in `e1` could also include these variables, and also the variables `v1`, `v2`, `v3`, or `v4` of the second follower, but all of these would be treated as parameters by the first follower.

The actual model (**ccmg71**) in EMPLIB uses a shortcut notation:

```
...
defh1.. h1 =e= sqrt(u1-x1) + sqrt(u2-x2) + sqrt(u3-x3) + sqrt(u4-x4);
e1.. 3*u1 + u2 + 2*u3 + u4 =e= 6;
...
$onecho > "%emp.info%"
bilevel x1 x2 x3 x4
min h1 * defh1 e1
min h2 * defh2 e2
$offecho
```

In the followers problem, the '*' notation indicates that this agent will optimize over all the variables used in `defh1` and `e1` that are not under the control of any other follower or the leader. In this case, this means `u1`, `u2`, `u3`, and `u4`. To avoid confusion, it is recommended that the modeler explicitly names all the variables in each followers problem as shown before.

5.25.6 Variational Inequalities

A variational inequality $VI(F, X)$ is to find $x \in X$:

$$\langle F(x), (z - x) \rangle \geq 0, \text{ for all } z \in X.$$

Here X is a closed (frequently assumed convex) set, defined for example as

$$X = \{x \mid x \geq 0, h(x) \geq 0\}.$$

Note that the first-order (minimum principle) conditions of a nonlinear program

$$\min_{z \in X} f(z)$$

are precisely of this form with $F(x) = \nabla f(x)$.

It is well known that such problems can be reformulated as complementarity problems when the set X has the representation $\{x \mid x \geq 0, h(x) \geq 0\}$ by introducing multipliers λ on the constraints $h(x) \geq 0$:

$$\begin{array}{ll} 0 \leq F(x) - \langle \lambda, \nabla h(x) \rangle & \perp \quad x \geq 0 \\ 0 \leq h(x) & \perp \quad \lambda \geq 0. \end{array}$$

If X has a different representation, this construction would be modified appropriately.

A simple two dimensional example may be useful to improve understanding. Let

$$F(x) = \begin{bmatrix} x_1 + 2 \\ x_1 + x_2 - 3 \end{bmatrix}, \quad X = \{x \geq 0 \mid x_1 + x_2 \leq 1\},$$

so that F is an affine function, but F is not the gradient of any function $f: \mathbf{R}^2 \rightarrow \mathbf{R}$. For this particular data, $VI(F, X)$ has a unique solution $x = (0, 1)$.

```
Set J / 1, 2 /;
Positive Variable x(J) 'vars, perp to f(J)';

Equations F(J), h;

F(J).. (x('1') + 2)$sameas(J,'1') + (x('1') + x('2') - 3)$sameas(J,'2') =n= 0 ;
h.. x('1') + x('2') =l= 1;

model simpleVI / F, h/;

file fx /"%emp.info%"/;
putclose fx 'vi F x h';

solve simpleVI using emp;
```

Note that the first lines of this file define the F and h using standard GAMS syntax and include the defining equations in the model **simpleVI**. The extension is the annotation "empinfo" file that indicates certain equations are to be treated differently by the EMP tool. The annotation simply says that the model is a VI (**vi**) that pairs **F** with **x** and that the remaining (unpaired) equations form the constraint set X . (Alternative notation allows the keyword **vi** to be replaced by **vifunc**.) Thus, model equations **F** define a function F that is to be part of a variational inequality, while the equations **h** define constraints of X . It is also acceptable in this setting to use the "empinfo" file defined by:

```
putclose fx 'vi F x';
```

In this case, by default, any equations that are given in the model statement but not included as a pair in the **vi** statement are automatically used to form X . An alternative way to write this model without using **sameas** is given in EMPLIB as **affinevi**.

Some subtleties related to VI's are demonstrated in the EMPLIB model **zerofunc**. In this model, the set X is defined using variables y and z , for which z does not appear in the definition of $F \equiv F_y$. In this case, the variable z is then matched with a "0" function. The "empinfo" file can be written in a number of different ways:

```
putclose fx 'vi F_y y';
```

or

```
putclose fx 'vi z F_y y';
```

or

```
putclose fx 'vi z F_y y gCons';
```

or

```
putclose fx 'vi F_z z F_y y gCons';
```

where **F_z** simply defines the zero function. To some extent, our preferred notation is the one listed third: it explicitly includes all the variables and constraints that are present in the model and does not require the modeler to define **F_z** at all.

Further example models in EMPLIB are **simplevi**, **simplevi2**, **simplevi3**, **target**, **traffic**, **traffic2**, and **transvi**.

Note also that the lower level problems of a bilevel program could be VI's instead of optimization problems - these problems are called Mathematical Programs with Equilibrium Constraints (MPEC) in the literature. Note that since MPCC is a special case of MPEC, the GAMS model type MPEC covers both. An example demonstrating this setup is given in EMPLIB as **multmpec**. The actual model to solve is:

$$\begin{aligned} & \min_{u,v,w,z} z \\ & \text{s.t. } \exp(z) + w = 2, z \geq 1 \\ & \quad (u, v) \text{ solves VI}([v + w + z - 1; u - \log(v)], \{(u, v) \mid u \geq 0, v \geq 0\}) \\ & \quad w \text{ solves VI}(w + z + 3, \{w \mid w \text{ free}\}) \end{aligned}$$

Note that the two VI's (due to the definitional sets) correspond respectively to a complementarity problem:

$$\begin{aligned} 0 \leq v + w + z - 1 & \quad \perp \quad u \geq 0 \\ 0 \leq u - \log(v) & \quad \perp \quad v \geq 0 \end{aligned}$$

and a linear equation:

$$w + z + 3 = 0$$

The actual GAMS code is as follows:

```

Positive Variable u;
Variables v, w, z;
Equations f1, f2, f3, h;

f1.. v + w + z =n= 1;
f2.. u =n= log(v);

f3.. w + z =n= -3;

h.. exp(z) + w =e= 2;

v.lo = 0; v.l = 1; z.lo = 1;

model mpecmod /all/;

$onecho > %emp.info%
bilevel
vi f1 u
f2 v
vi f3 w
$offecho

solve mpecmod using emp min z;

```

The initial level value for v ($v.l = 1$) is needed to protect the evaluation of $\log(v)$. The two complementarity problems are specified in the empinfo file (it is not really necessary to split these VI's apart, but it may give information to a solver that can be exploited). It is of course possible to write the MPCC directly in GAMS using the model type MPEC instead of EMP.

5.25.7 Embedded Complementarity Systems

A different type of embedded optimization model that arises frequently in applications is:

$$\begin{aligned}
 &\max_x f(x, y) \\
 &\text{s.t.} \quad g(x, y) \leq 0 \quad (\perp p \geq 0) \\
 &\quad \quad H(x, y, p) = 0 \quad (\perp y \text{ free})
 \end{aligned}$$

Note the difference here: the optimization problem is over the variable x , and is parameterized by the variable y . The choice of y is fixed by the (auxiliary) complementarity relationships depicted here by H . Note that the H equations are not part of the optimization problem, but are essentially auxiliary constraints to tie down remaining variables in the model.

A specific example is:

$$\begin{aligned}
 &\max_x x \\
 &\text{s.t.} \quad x + y \leq 1 \\
 &\quad \quad -3x + y = 0.5 \quad (\perp y \text{ free})
 \end{aligned}$$

which is found in the EMPLIB model **simpequil2**:

```

Variables y;
Positive variables x;
Equations optcons, vicons;

optcons.. x + y =l= 1;
vicons.. -3*x + y =e= 0.5;

model comp / optcons, vicons /;

file info / '%emp.info%' /;
put info / 'equilibrium';
put / 'max x optcons';
putclose / 'vi vicons y';

solve comp using emp;

```

In order that this model can be processed correctly as an EMP, the modeler provides additional annotations to the model defining equations in an "empinfo" file. Specifically, first it is indicated that the problem is an equilibrium problem involving one or more agent problems. Next, the first agent is defined as an optimizer (over x). Finally, the second agent is defined as solving a VI in y . Armed with this additional information, the EMP tool automatically creates the following MCP:

$$\begin{array}{lll} 0 \leq -1 + p & \perp & x \geq 0 \\ 0 \leq 1 - x - y & \perp & p \geq 0 \\ 0 = -3x + y - 0.5 & \perp & y \text{ free,} \end{array}$$

(which is formed by the steps we outline below). EMP explicitly enforces the rule that every variable and constraint is under the control of exactly one agent. Thus a constraint or a variable cannot appear in both the max problem and the VI problem.

The above example is slightly simpler than the general form described above in which H is a function of x , y , and p , the multiplier on the constraint of the optimization problem. The problem is that we do not have that variable around in the model code if we only specify the optimization problem there. This occurs for example in the classical PIES Model due to Hogan. In this setting, the problem is described by a linear program

$$\begin{array}{ll} \min_x & c^T x \\ \text{s.t.} & Ax = q(p) \\ & Bx = b \\ & x \geq 0 \end{array}$$

in which the quantity q is a function of p , which is a multiplier on one of the LP constraints. To do this in EMP, we simply add the annotation:

```
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;

file myinfo /'%emp.info%'/;
put myinfo 'equilibrium';
put 'min obj c o ct ot lt ht defobj dembal cmbal ombal lmbal hmbal ruse';
putclose 'dualvar p dembal';

solve piesemp using emp;
```

where **dembal** is the name of the constraint for which **p** needs to be the multiplier. The full model is found in the EMPLIB model **pies**. Two final points: the **dualvar** directive identifies the variable **p** with the multiplier on the **dembal** constraint, and all variables and constraints must be owned by a single agent. In this case, since there is only one agent (the minimizer), all constraints of the model are explicitly claimed, along with all variables except for **p**. However, next, **p** is identified with the **dembal** constraint, which is owned by the min agent, and hence **p** is also owned by that agent.

There are several shorthands possible here. The first is that the explicit statement of variables can be replaced by the '*' form:

```
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;

file myinfo /'%emp.info%'/;
put myinfo 'equilibrium';
put 'min obj * defobj dembal cmbal ombal lmbal hmbal ruse';
```

Alternatively, an even shorter version is possible since there is only one agent present in this model, namely:

```
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;

file myinfo /'%emp.info%'/;
putclose myinfo 'dualvar p dembal';

solve piesemp using emp minimizing obj;
```

Note that in this form, all the variables and constraints of the original model are included in the (single) agents problem, and the original variable p is identified in the constructed MCP with the multiplier on the `dembal` constraint.

In the general case where the "empinfo" file contains all three lines:

```
min x optcons
vi vicons y
dualvar p optcons
```

namely that the function H that is defined in `vicons` is complementary to the variable y (and hence the variable y is a parameter to the optimization problem), and furthermore that the dual variable associated with the equation `optcons` in the optimization problem is one and the same as the variable p used to define H , the EMP tool automatically creates the following MCP:

$$\begin{array}{lll} 0 = \nabla_x \mathcal{L}(x, y, p) & \perp & x \text{ free} \\ 0 \geq -\nabla_p \mathcal{L}(x, y, p) & \perp & p \leq 0 \\ 0 = H(x, y, p) & \perp & y \text{ free,} \end{array}$$

where the Lagrangian is defined as

$$\mathcal{L}(x, y, p) = f(x, y) - \langle p, g(x, y) \rangle.$$

Essentially, this MCP consists of the first order optimality conditions of the optimization problem, coupled with the VI that is the second agents problem. An example that does both of these things together is provided in EMPLIB as **scarfemp-primal**.

Note that since the PIES model has no y variables, this is a special case of the general form in which the second agents (VI) problem is simply not present.

Example models are **ferris43**, **flipper pies**, **scarfemp-dual**, **simpequil**, **transecs**, and **transeql**.

5.25.8 MOPECs

MOPECs (Multiple Optimization Problems with Equilibrium Constraints) are a simple conceptual extension of the aforementioned embedded complementarity system. Instead of having a single optimizing agent and a variational inequality, one instead allows multiple optimizing agents coupled with an equilibrium constraint (the variational inequality).

Perhaps the most popular use of this formulation is where competition is allowed between agents. A standard method to deal with such cases is via the concept of Nash Games. In this setting x^* is a Nash Equilibrium if

$$x_i^* \in \arg \min_{x_i \in X_i} \ell_i(x_i, x_{-i}^*, q), \forall i \in \mathcal{I},$$

where x_{-i} are other players decisions and the quantities q are given exogenously, or via complementarity:

$$0 \leq H(x, q) \quad \perp \quad q \geq 0.$$

This mechanism is extremely popular in economics, and Nash famously won the Nobel Prize for his contributions to this literature.

This format is again an EMP, more general than the example given above in two respects. Firstly, there is more than one optimization problem specified in the embedded complementarity system. Secondly, the parameters in each optimization problem consist of two types. Firstly, there are the variables q that are tied down by the auxiliary complementarity condition and hence are treated as parameters by the i th

Nash player. Also there are the variables x_{-i} that are treated as parameters by the i th Nash player, but are treated as variables by a different player j .

While we do not specify the syntax here for these issues, **EMPLIB** provides examples that outline how to carry out this matching within GAMS. Finally, two points of note: first it is clear that the resulting model is a complementarity problem and can be solved using PATH, for example. Secondly, performing the conversion from an embedded complementarity system or a Nash Game automatically is a critical step in making such models practically useful.

We note that there is a large literature on discrete-time finite-state stochastic games: this has become a central tool in analysis of strategic interactions among forward-looking players in dynamic environments. The model of dynamic competition in an oligopolistic industry given in [78] is exactly in the format described above, and has been used extensively in applications such as advertising, collusion, mergers, technology adoption, international trade and finance. Ongoing work aims to use the EMP format to model these problems.

5.25.9 Extended Nonlinear Programs

Optimization models have traditionally been of the form (NLP). Specialized codes have allowed certain problem structures to be exploited algorithmically, for example simple bounds on variables. However, for the most part, assumptions of smoothness of f , g and h are required for many solvers to process these problems effectively. In a series of papers, Rockafellar and colleagues [202] [203] [204] have introduced the notion of extended nonlinear programming, where the (primal) problem has the form:

$$\min_{x \in X} f(x) + \theta(g_1(x), \dots, g_m(x)). \quad (\text{ENLP})$$

In this setting, X is assumed to be a nonempty polyhedral set, and the functions $f, g_1, \dots, g_m$ are smooth. The function θ can be thought of as a generalized penalty function that may well be nonsmooth. However, when θ has the form

$$\theta(u) = \sup_{y \in Y} \{\langle y, u \rangle - k(y)\}, \quad (\theta \text{ conj})$$

a computationally exploitable and theoretically powerful framework can be developed based on conjugate duality. A key point for computation and modeling is that the function θ can be fully described by defining the set Y and the function k . Furthermore, from a modeling perspective, an extended nonlinear program can be specified simply by defining the functions $f, g_1, \dots, g_m$ in the manner already provided by the modeling system, with the additional issue of simply defining Y and k . Conceptually, this is not much harder than what is carried out already, but leads to significant enhancements to the types of models that are available. Once a modeler determines which constraints are treated via which choice of k and Y , the EMP model interface automatically forms an equivalent variational inequality or complementarity problem. As we show later, there may be alternative formulations that are computationally more appealing; such reformulations can be generated using different options to JAMS.

5.25.9.1 Forms of theta

The EMP model type makes the problem format (ENLP) available to users in GAMS. As special cases, we can model piecewise linear penalties, least squares, and L_1 approximation problems, as well as the notion of soft and hard constraints.

For ease of exposition, we now describe a subset of the types of functions θ that can be generated by particular choices of Y and k . In many cases, the function θ is separable, that is

$$\theta(u) = \sum_{i=1}^m \theta_i(u_i),$$

so we can either specify θ_i or θ itself.

Extended nonlinear programs include the classical nonlinear programming form (NLP) as a special case. This follows from the observation that if K is a closed convex cone, and we let ψ_K denote the "indicator function" of K defined by:

$$\psi_K(u) = \begin{cases} 0 & \text{if } u \in K, \\ \infty & \text{else,} \end{cases}$$

then (NLP) can be rewritten as:

$$\min_x f(x) + \psi_K((g(x), h(x))), \quad K = \mathbf{R}_-^m \times \{0\}^p,$$

where m and p are the dimensions of g and h respectively and $\mathbf{R}_-^m = \{u \in \mathbf{R}^m \mid u \leq 0\}$. An elementary calculation shows that

$$\psi_K(u) = \sup_{v \in K^\circ} \langle u, v \rangle,$$

where $K^\circ = \{u \mid \langle u, v \rangle \leq 0, \forall v \in K\}$ is the polar cone of the given cone K . Thus, when $\theta(u) = \psi_K(u)$ we simply take $k \equiv 0$ and $Y = K^\circ$. In our example, $K^\circ = \mathbf{R}_+^m \times \mathbf{R}^p$. To some extent, this is just a formalism that allows us to claim the classical case as a specialization; however when we take the cone K to be more general than the polyhedral cone used above, we can generate conic programs for example.

The second example involves a piecewise linear function θ : Formally, for $u \in \mathbf{R}$,

$$\theta(u) = \begin{cases} \rho u & \text{if } u \geq 0, \\ \sigma u & \text{else.} \end{cases}$$

In this case, simple calculations prove that θ has the form (θ conj) for the choices

$$k \equiv 0 \text{ and } Y = [\sigma, \rho].$$

The special case where $\sigma = -\rho$ results in

$$\theta(u) = \rho |u|.$$

This allows us to model nonsmooth L_1 approximation problems. Another special case results from the choice of $\sigma = -\gamma$, $\rho = 0$, whereby

$$\theta(u) = \gamma \max\{-u, 0\}.$$

This formulation corresponds to a soft penalization on an inequality constraint, namely if $\theta(-g_1(x))$ is used then nothing is added to the objective function if $g_1(x) \leq 0$, but $\gamma g_1(x)$ is added if the constraint $g_1(x) \leq 0$ is violated. Contrast this to the classical setting above, where ∞ is added to the objective if the inequality constraint is violated. It is interesting to see that truncating the set Y , which amounts to bounding the multipliers, results in replacing the classical constraint by a linearized penalty.

The third example involves a more interesting choice of k . If we wish to replace the "absolute value" penalization given above by a quadratic penalization (as in classical least squares analysis), that is

$$\theta(u) = \gamma u^2$$

then a simple calculation shows that we should take

$$k(y) = \frac{1}{4\gamma} y^2 \text{ and } Y = \mathbf{R}.$$

By simply specifying this different choice of k and Y we can generate such models easily and quickly within the modeling system. Note, however, that the reformulation we would use in $\theta(u) = \rho |u|$ and $\theta(u) = \gamma u^2$ are very different as we shall explain in the simple example below. Furthermore, in many applications it has become popular to penalize violations using a quadratic penalty only within a certain interval, afterwards switching to a linear penalty (chosen to make the penalty function θ continuously differentiable - see [130]). That is:

$$\theta(u) = \begin{cases} \gamma u - \frac{1}{2}\gamma^2 & \text{if } u \geq \gamma \\ \frac{1}{2}u^2 & \text{if } u \in [-\gamma, \gamma] \\ -\gamma u - \frac{1}{2}\gamma^2 & \text{else.} \end{cases}$$

Such functions arise from quadratic k and simple bound sets Y . In particular, the somewhat more general function

$$\theta(u) = \begin{cases} \gamma\beta^2 + \rho(u - \beta) & \text{if } u \geq \beta \\ \gamma u^2 & \text{if } u \in [\alpha, \beta] \\ \gamma\alpha^2 + \sigma(u - \alpha) & \text{else} \end{cases}$$

arises from the choice of

$$k(y) = \frac{1}{4\gamma}y^2 \text{ and } Y = [\sigma, \rho],$$

with $\alpha = \frac{\sigma}{2\gamma}$ and $\beta = \frac{\rho}{2\gamma}$.

The final example that we give is that of L_∞ penalization. This example is different to the examples given above in that θ is not separable. However, straightforward calculation can be used to show

$$\theta(u) = \max_{i=1,\dots,m} u_i$$

results from the choice of

$$k \equiv 0 \text{ and } Y = \left\{ y \in \mathbf{R}^m \mid y \geq 0, \sum_{i=1}^m y_i = 1 \right\},$$

that is, Y is the unit simplex.

5.25.9.2 Underlying theory

The underlying structure of θ leads to a set of extended optimality conditions and an elegant duality theory. This is based on an extended form of the Lagrangian:

$$\begin{aligned} \mathcal{L}(x, y) &= f(x) + \sum_{i=1}^m y_i g_i(x) - k(y) \\ x &\in X, y \in Y \end{aligned}$$

Note that the Lagrangian $\mathcal{L}$ is smooth - all the nonsmoothness is captured in the θ function. The theory is an elegant combination of calculus arguments related to g_i and its derivatives, and variational analysis for features related to θ .

It is shown in [203] that under a standard constraint qualification, the first-order conditions of (ENLP) are precisely in the form of the following variational inequality:

$$\text{VI} \left(\begin{bmatrix} \nabla_x \mathcal{L}(x, y) \\ -\nabla_y \mathcal{L}(x, y) \end{bmatrix}, X \times Y \right). \quad (\text{ENLP VI})$$

When X and Y are simple bound sets, this is simply a complementarity problem.

Note that EMP exploits this result. In particular, if an extended nonlinear program of the form (ENLP) is given to EMP, then the optimality conditions (ENLP VI) are formed as a variational inequality problem and can be processed as outlined above. For a specific example, we cite the fact that if we use the (classical) choice $k \equiv 0$ and $Y = K^\circ$, then the optimality conditions of (ENLP) are precisely the standard complementarity problem given as (ENLP VI). While this is of interest, we believe that other choices of k and Y may be more useful and lead to models that have more practical significance.

Under appropriate convexity assumptions on this Lagrangian, it can be shown that a solution of the VI (ENLP VI) is a saddle point for the Lagrangian on $X \times Y$. Furthermore, in this setting, the saddle point generates solutions to the primal problem (ENLP) and its dual problem:

$$\max_{y \in Y} d(y), \text{ where } d(y) = \inf_{x \in X} \mathcal{L}(x, y),$$

with no duality gap.

Unfortunately, the perturbations y in Rockafellar's theory are precisely the negative of those used throughout the GAMS system. Thus, we need to replace y by $-y$ throughout in the above to recover the same multipliers as those GAMS uses.

5.25.9.3 A simple example

As an example, consider the problem

$$\begin{aligned} \min_{x_1, x_2, x_3} \quad & \exp(x_1) + 5\|\log(x_1) - 1\|^2 + 2\max(x_2^2 - 2, 0) \\ \text{s.t.} \quad & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0. \end{aligned}$$

In this problem, we would take

$$X = \{x \in \mathbf{R}^3 \mid 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0\}.$$

The function θ essentially treats 3 separable pieces:

$$\begin{aligned} g_1(x) &= \log(x_1) - 1, \\ g_2(x) &= x_2^2 - 2, \\ g_3(x) &= x_1/x_2 - \log(x_3). \end{aligned}$$

A classical problem would force $g_1(x) = 0$, $g_2(x) \leq 0$, and $g_3(x) = 0$, while minimizing $f(x) = \exp(x_1)$. In our problem, we still force $g_3(x) = 0$, but apply a (soft) least squares penalty on $g_1(x)$ and a smaller one-sided penalization on $g_2(x)$. The above formulation is nonsmooth due to the "max" term in the objective function; in practice we could replace this by:

$$\begin{aligned} \min_{x_1, x_2, x_3, w} \quad & \exp(x_1) + 5\|\log(x_1) - 1\|^2 + 2w \\ \text{s.t.} \quad & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0 \\ & w \geq x_2^2 - 2, w \geq 0 \end{aligned}$$

and recover a standard form NLP. If the penalty on $g_1(x)$ would be replaced by a one-norm penalization (instead of least squares), we would have to play a similar game, moving the function $g_1(x)$ into the constraints and adding additional variable(s). To some extent, this seems unnatural - a modeler should be able to interchange the penalization without having to reformulate the problem from scratch. The proposed extended NLP would not be reformulated at all by the modeler, but allows all these "generalized constraints" to be treated in a similar manner within the modeling system. The actual formulation would take:

$$\theta(u) = \theta_1(u_1) + \theta_2(u_2) + \theta_3(u_3)$$

where

$$\begin{aligned} \theta_1(u_1) &= 5u_1^2, \\ \theta_2(u_2) &= 2\max(u_2, 0), \\ \theta_3(u_3) &= \psi_{\{0\}}(u_3). \end{aligned}$$

The discussion above allows us to see that

$$\begin{aligned} Y &= -(\mathbf{R} \times [0, 2] \times \mathbf{R}), \\ k(y) &= \frac{1}{20}y_1^2 + 0 + 0. \end{aligned}$$

The corresponding Lagrangian is the smooth function:

$$\mathcal{L}(x, y) = f(x) - \sum_{i=1}^3 y_i g_i(x) - k(y).$$

The corresponding VI (ENLP VI) can almost be formulated in GAMS (except that the linear constraint in X cannot be handled currently except by introducing a $\theta_4(x)$). Thus

$$g_4(x) = 3x_1 + x_2 - 5, \theta_4(u) = \psi_{\mathbf{R}_-}$$

resulting in the following choices for Y and k :

$$Y = -(\mathbf{R} \times [0, 2] \times \mathbf{R} \times \mathbf{R}_+),$$

$$k(y) = \frac{1}{20}y_1^2 + 0 + 0 + 0.$$

Since X and Y are now simple bound sets, (ENLP VI) is now a complementarity problem and can be solved for example using PATH. A simple "empinfo" file details the choices of Y and k from the implemented library:

```

Adjustequ
e1 sqr 5
e2 MaxZ 2

```

5.25.9.4 Reformulation as a classical NLP

Suppose

$$\theta(u) = \sup_{y \in Y} \{ \langle u, y \rangle - \frac{1}{2} \langle y, Qy \rangle \}$$

for a polyhedral set $Y \in \mathbf{R}^m$ and a symmetric positive semidefinite $Q \in \mathbf{R}^{m \times m}$ (possibly $Q = 0$).

Suppose further that

$$X = \{x \mid Rx \leq r\}, Y = \{y \mid S^T y \leq s\},$$

$$Q = DJ^{-1}D^T, F(x) = (g_1(x), \dots, g_m(x)),$$

where J is symmetric and positive definite (for instance $J = I$). Then, as outlined by [204], the optimal solutions $\bar{x}$ of (ENLP) are the $\bar{x}$ components of the optimal solutions $(\bar{x}, \bar{z}, \bar{w})$ to

$$\begin{aligned} \min \quad & f(x) + \langle s, z \rangle + \frac{1}{2} \langle w, Jw \rangle \\ \text{s.t.} \quad & Rx \leq r, z \geq 0, \bar{F}(x) - Sz - Dw = 0. \end{aligned}$$

The multiplier on the equality constraint in the usual sense is the multiplier associated with $\bar{x}$ in the extended Lagrangian for (ENLP). (Note that a Cholesky factorization may be needed to determine D .)

It may be better to solve this reformulated NLP than to solve the VI (ENLP VI). However, it is important that we can convey all types of nonsmooth optimization problems to a solver as smooth optimization problems, and hence it is important to communicate the appropriate structure to the solver interface. We believe that specifying Y and k is a theoretically sound way to do this.

5.25.10 Disjunctive Programs (LogMIP)

There are many ways that the EMP model type can be used for further extensions to the modeling capabilities of a given system. In particular, the procedures outlined in [242] [102] for disjunctive programming extensions are also implemented within the EMP model type.

The disjunctive programming procedures are also known as the LogMIP 2.0 solver for solving linear and nonlinear disjunctive programming problems involving binary variables and disjunction definitions for modeling discrete choices. While the modeling and solution of these disjunctive optimization problems

has not yet reached the stage of maturity and reliability as LP, MIP and NLP modeling, these problems have a rich area of applications.

LogMIP 2.0 has been developed by Dr. Aldo Vecchietti from INGAR (Santa Fe, Argentina) and Professor Ignacio E. Grossmann from Carnegie Mellon University (Pittsburgh, USA), and supersedes its previous version, LogMIP 1.0 (GAMS releases 22.6 (December 2007) to 23.6 (December 2010)). Changes in version 2.0 are at the level of language, where now the EMP syntax and modeltype is used, and at the level of solvers, where Big-M and convex-hull relaxations are combined. For more information see the website <http://www.logmip.ceride.gov.ar/> and the documentation <http://www.logmip.ceride.gov.ar/files/pdfs/newUserManual.pdf>.

One simple example to highlight the disjunctive programming feature is the notion of an ordering of tasks, namely that either job i completes before job j starts or the converse, i.e., that the jobs cannot overlap. Such a disjunction can be specified using an empinfo file containing lines:

```
disjunction * seq(i,j) else seq(j,i)
```

In such an example, one can implement a Big-M method, employ indicator constraints, or utilize a convex hull reformulation. The convex hull reformulation is the default strategy; to utilize the Big-M formulation, the additional option

```
default bigm 1000
```

would add binary variables and constraints to impose the disjunction using a Big-M value of 1000. Alternatively, the option setting

```
default indic
```

writes out a model and an option file that implements a reformulation using indicator constraints, which can be handled by the solvers CPLEX, SCIP, and XPRESS. The EMPLIB model **sequence** is sequencing model that implements all of these options.

More complicated (nonlinear) examples make the utility of this approach clearer. The design of a multiproduct batch plan with intermediate storage described in [241] and a synthesis problem involving 8 processes from [238] are also included in the EMP model library. As a final example, the gasoline emission model outlined in [101] is precisely in the form that could exploit the features of EMP related to (nonlinear) disjunctive programming.

5.25.11 Empinfo file details

We have explained above many of the standard vectorized ways to write an "empinfo" file. The "empinfo" file has a vectorized format and a more powerful (but more complex) scalar version. We describe some of the features of the scalar version in this section.

An example of the use of the scalar syntax is given below

```
file info / '%emp.info%' /;
put info / 'equilibrium';
loop(h,
  put / 'min' obj(h) /;
  loop(j, put x(h,j)); put /;
  loop(k, put z(h,k));
  put / costdef(h) /;
  loop(i, put nodebal(h,i)); put /;
);
loop(a, put 'vi',flowdef(a),f(a) /);
```

This is an example of a MOPEC in which the optimization agents are indexed by h and each of these agents control variables x_{hj} and z_{hk} . The objective function for each h is defined in `costdef`, the constraints of each minimization problem are defined in `nodebal`, and the equilibrium constraints that link all the optimization problems are a VI defined by variables f_a and functions within `flowdef`. Sometimes it is necessary to use syntax that generates the "tl" fields of sets, but this seems only necessary when abnormal side conditions are needed.

The format of the empinfo file is given below:

```

Disjunction [chull [big eps] | bigM [big eps threshold] | indic]
            [NOT] var[*] [NOT] {equ} {ELSEIF [NOT] var[*] [NOT] {equ}} [ELSE [NOT] {equ}]

Default [chull [big eps] | bigM [big eps threshold] | indic]

ParallelStep1 {equ|*}

AdjustEqu equ abs|sqr|maxz|... {weight}

ModelType MCP|NLP|MIP|...

BiLevel {var} {MAX|MIN obj {var|*} {[ -] equ}} {VI {var|*} {[ -] equ var} {[ -] equ}}
        {DualVar {var [-] equ}}

Equilibrium {Implicit {var equ}} {Visol {equ}}
            {MAX|MIN obj {var|*} {[ -] equ}} {VI {var|*} {[ -] equ var} {[ -] equ}}
            {DualVar {var [-] equ}}

VI {var|*} {[ -] equ var} {[ -] equ}

DualEqu {[ -] equ var}

DualVar {var [-] equ}

-----
[ ] optional      | exclusive      { } can be repeated

```

5.26 KESTREL - Remote Solver Execution on NEOS Servers

5.26.1 Background

The Kestrel client/server is a way of sending your GAMS solve job to be solved via the NEOS Server from within your usual GAMS modeling environment and receiving results that can be processed as with any local solver. Starting with distribution 23.7 the Kestrel solver is part of the GAMS distribution. The solve statement using the GAMS/KESTREL solver invokes a client program that sends your problem to a solver running on one of the NEOS Server's remote computers. The results from the NEOS Server are eventually returned through Kestrel to GAMS, where you can view and manipulate them locally in the usual way. The introduction below covers everything you need to know to start using GAMS/KESTREL. Further information about more advanced features and other uses of Kestrel can be found at the [Kestrel page on the NEOS Server](#). Note that GAMS/Kestrel requires a Python 2 installation on platforms other than Windows. The interpreter executable (`python2`) needs to be found in the `PATH` environment variable

5.26.1.1 Kestrel and IBM DOcloud

With GAMS 24.6 the GAMS/Kestrel client has been adjusted to work with IBM's cloud service **Decision Optimization on Cloud (DOcloud)**. When the Kestrel option `docloudurl` is set, the generated model instance will be automatically translated into an MPS format and send to DOcloud and solved by Cplex in IBM's cloud. So no GAMS/Cplex license is required on your local machine. You as a user need to register with IBM on the web page mentioned about and pay IBM for the solution time spend in IBM's cloud. IBM provides details how to **get started** with DOcloud.

5.26.2 Using GAMS/KESTREL

The Kestrel solver can be used to solve a GAMS model remotely. For example, consider the **trnsport model**. It can be solved locally in GAMS through the following statements,

```
model transport /all/;
solve transport using lp minimizing z;
```

which specify the **trnsport** model and solve it with the default linear programming solver. We can add an option statement to the code to explicitly specify the solver. For example, if we change the linear programming solver to GAMS/MINOS, the code becomes

```
model transport /all/;
option lp=minos;
solve transport using lp minimizing z;
```

To solve the same problem remotely through the NEOS Server, we simply change the linear programming solver to Kestrel. Without an option file Kestrel will submit the model instance to the NEOS server and use the default LP solver on NEOS.

```
option lp=kestrel;
solve transport using lp minimizing z;
```

We can support a Kestrel option file and determine the solver on the NEOS server:

```
transport.optfile=1;
option lp=kestrel;
solve transport using lp minimizing z;
$echo kestrel_solver minos > kestrel.opt
```

The statement `transport.optfile=1` specifies that an options file, called **kestrel.opt**, will be used. The options file contains the remote solver name as well as any options for the remote solver. We instruct the Kestrel solver to use GAMS/MINOS as the remote solver by writing the following **kestrel.opt** file:

```
kestrel_solver minos
```

If you do not know what solvers are available via GAMS/KESTREL on NEOS, submitting a job with a nonexistent solver set will return a list of enabled solvers. If you want to change the URL of the server, you can specify the option **neos_server**. The complete format of the parameter is **protocol://host:port**.

A subsequent run of the code through the GAMS interpreter results in the transport model being solved through the NEOS Server with the GAMS/MINOS solver. Once the job is submitted to the NEOS Server, a job number, password, and Web address are displayed to the screen, which provide information on accessing the job and viewing the intermediate output, for example,

```

--- Executing KESTREL
Job has been submitted to Kestrel
Kestrel/NEOS Job number      : 93478
Kestrel/NEOS Job password    : utiwtxTK
Check the following URL for progress report :
    https://neos-server.org/neos/cgi-bin/nph-neos-solver.cgi?admin=results&jobnumber=93478&pass=uti

```

To look at the solver's output while it is running, point your browser at the URL given in the Kestrel output as shown above, and click on **View Intermediate Results** in the web page that appears. This will take you to another page that shows all of the output produced by the solver for your problem so far. To track the solver's progress, simply update this page periodically.

If the NEOS Server or the network becomes unavailable after the submission, a particular job can be retrieved by setting both the kestrel job and kestrel password in the options file.

```

kestrel_solver minos
kestrel_job 93478
kestrel_password utiwtxTK

```

Re-issuing the command `gams trnsport` with this options file will retrieve the results for the specified job number.

By specifying `neos_username` and `neos_user_password` in the option file, you can submit an authenticated job using your NEOS user account. Authenticated jobs will appear in your user account on the NEOS website.

```

neos_username username
neos_user_password password

```

5.26.2.1 Using GAMS/KESTREL with IBM DOcloud

In order to use GAMS/Kestrel to solve model instances with Cplex on IBM's DOcloud, the only thing that needs to be done is to provide a different option file. The option `docloud_url` triggers the submission to IBM's DOcloud rather than NEOS. You need an account on DOcloud (and pay IBM for the Cplex solution time in their cloud). Some additional account information needs to be specified in the Kestrel option `docloud_key`. The use of Cplex in DOcloud is limited to solve a model instance, special options that are available in the GAMS/Cplex system, like [IIS](#) or [FeasOpt](#) cannot be used (yet) through Kestrel/DOcloud. Moreover, for problems with discrete variables, only the primal solution is returned. If you want to specify Cplex options this needs to be done with a Cplex parameter file which is quite different from the GAMS/Cplex option file. You can use a GAMS/Cplex option file and have the additional option [WriteParam](#) to produce such a Cplex parameter file. The Cplex parameter file might have a few more options compared to the GAMS/Cplex option file because some [GAMS options](#) set Cplex parameters. Please note that you can produce the Cplex parameter file with GAMS/Cplex even if you do not have a license for GAMS/Cplex as long as you run a demo sized model (e.g. from the GAMS Model Library) to produce the Cplex parameter file. The following GAMS/Cplex optfile

```

lpmethod 4
advind 0
eprhs 1e-4
scaind 1
writeparam cplex.prm

```

produces the Cplex parameter file `cplex.prm` which can be submitted to Kestrel/DOcloud via the option `docloud_prmfile`:

```
CPLEX Parameter File Version 12.6.3.0
CPX_PARAM_ADVIND          0
CPX_PARAM_EPRHS          1.0000000000000000e-04
CPX_PARAM_SIMDISPLAY      2
CPX_PARAM_SCAIND          1
CPX_PARAM_TILIM          1.0000000000000000e+03
CPX_PARAM_LPMETHOD      4
CPX_PARAM_THREADS        1
CPX_PARAM_PARALLELMODE    1
```

Users of GAMS/Kestrel on platforms other than Windows will need to install the [GAMS Python API](#) and the IBM DOcloud [Python package](#).

5.27 KNITRO

5.27.1 Introduction

Artelys Knitro is a software package for finding local solutions of both continuous (i.e. smooth) optimization problems, with or without constraints, and discrete optimization problems with integer or binary variables. Even though Knitro has been designed for solving large-scale general problems, it is efficient for solving all of the following classes of optimization problems:

- unconstrained,
- bound constrained,
- equality constrained,
- systems of nonlinear equations,
- least squares problems,
- linear programming problems (LPs),
- quadratic programming problems (QPs),
- general (inequality) constrained problems,
- (convex) mixed integer nonlinear programs (MINLP) of moderate size.

The Knitro package provides the following features:

- Efficient and robust solution of small or large problems,
 - Solvers for both continuous and discrete problems,
 - Derivative-free, 1st derivative and 2nd derivative options,
 - Both interior-point (barrier) and active-set optimizers,
 - Both feasible and infeasible versions,
 - Both iterative and direct approaches for computing steps,
-

The problems solved by Knitro have the form

$$\begin{array}{lll} \text{minimize} & f(x) & (1a) \\ \text{subject to} & c^L \leq c(x) \leq c^U & (1b) \\ & b^L \leq x \leq b^U, & (1c) \end{array}$$

where the variables x can be continuous, binary, or integer. This allows many forms of constraints, including bounds on the variables. Knitro requires that the functions $f(x)$ and $c(x)$ be smooth functions.

Knitro implements both state-of-the-art interior-point and active-set methods for solving nonlinear optimization problems. In the interior method (also known as a barrier method), the nonlinear programming problem is replaced by a series of barrier sub-problems controlled by a barrier parameter μ . The algorithm uses trust regions and a merit function to promote convergence. The algorithm performs one or more minimization steps on each barrier problem, then decreases the barrier parameter, and repeats the process until the original problem (1) has been solved to the desired accuracy.

Knitro provides two procedures for computing the steps within the interior point approach. In the version known as **Interior/CG** each step is computed using a projected conjugate gradient iteration. This approach differs from most interior methods proposed in the literature in that it does not compute each step by solving a linear system involving the KKT (or primal-dual) matrix. Instead, it factors a projection matrix, and uses the conjugate gradient method, to approximately minimize a quadratic model of the barrier problem.

The second procedure for computing the steps, which we call **Interior/Direct**, always attempts to compute a new iterate by solving the primal-dual KKT matrix using direct linear algebra. In the case when this step cannot be guaranteed to be of good quality, or if negative curvature is detected, then the new iterate is computed by the **Interior/CG** procedure.

Knitro also implements an active-set sequential linear-quadratic programming (SLQP) algorithm which we call **Active**. This method is similar in nature to a sequential quadratic programming method but uses linear programming sub-problems to estimate the active-set at each iteration. This active-set code may be preferable when a good initial point can be provided, for example, when solving a sequence of related problems.

For problems with discrete variables, Knitro provides two variants of the branch and bound algorithm. The first is a standard implementation, while the second is specialized for convex, mixed-integer nonlinear problems.

We encourage the user to try all algorithmic options to determine which one is more suitable for the application at hand. For guidance on choosing the best algorithm see section [Algorithm Options](#).

For a detailed description of the algorithm implemented in **Interior/CG** see [50] and for the global convergence theory see [51]. The method implemented in **Interior/Direct** is described in [251]. The **Active** algorithm is described in [53] and the global convergence theory for this algorithm is in [54]. An important component of Knitro is the HSL routine MA27 [121] which is used to solve the linear systems arising at every iteration of the algorithm. In addition, the **Active Set** algorithm in Knitro may make use of the COIN-OR Clp linear programming solver module. The version used in Knitro may be downloaded from <http://www.artelys.com/tools/clp/>.

5.27.2 Usage

Basic details of solver usage, including how to choose Knitro as the solver and how to use a solver-specific option file, are part of Chapter [Solver Usage](#).

As an NLP solver, Knitro can also be used to solve linear programs (LP), and both convex and nonconvex quadratic programs (QCP).

5.27.3 GAMS Options

The following [GAMS options](#) are used by the GAMS/Knitro link:

- Option ResLim = x;
Sets the time limit in seconds. If this limit is exceeded the solver will terminate and pass on the current solution to GAMS. See also [reslim](#) in section [GAMS options](#).
- Option SysOut = On;
This option sends additional Knitro messages to the GAMS listing file. It is useful in case of a solver failure or to get algorithmic details. See also [sysout](#) in section [GAMS options](#).
- *ModelName*.optCA = x;
Absolute gap stop criterion for a discrete problem. The Knitro option [mip_integral_gap_abs](#) takes its default from this value. See also [optca](#) in section [GAMS options](#).
- *ModelName*.optCR = x;
Relative gap stop criterion for a discrete problem. The Knitro option [mip_integral_gap_rel](#) takes its default from this value. See also [optcr](#) in section [GAMS options](#).

5.27.4 Summary of Knitro Options

The Knitro options file `knitro.opt` allows the user to easily set options controlling Knitro's behavior. Options are set by specifying a keyword and a corresponding value on a line in the `knitro.opt` file. Lines that begin with a `#` character are treated as comments and blank lines are ignored. For example, to set the maximum allowable number of iterations to 500, one could use the following options file:

5.27.4.1 Barrier options

Option	Description	Default
bar_directinterval	limit on consecutive CG steps before Knitro will try to force a direct linear algebra step	10
bar_feasible	specifies whether special emphasis is placed on getting and staying feasible	0
bar_feasmodetol	tolerance for activation of <code>bar_feasible</code> mode	1e-4
bar_initmu	initial barrier parameter value	1e-1
bar_initpt	initial point strategy for barrier algorithms	0
bar_maxbacktrack	limit on backtracks during the linesearch of the Interior/Direct algorithm	3
bar_maxcrossit	limit on crossover iterations	0
bar_maxrefactor	limit on KKT refactorizations per iteration of the Interior/Direct algorithm	auto
bar_murule	controls the barrier parameter update strategy	0

Option	Description	Default
bar_pencons	controls whether a penalty approach is applied to the constraints	auto
bar_penrule	controls penalty parameter strategy used to accept a trial iterate	auto
bar_refinement	toggles barrier solution refinement method	0
bar_relaxcons	controls application of a relaxation approach to the constraints	2
bar_switchrule	controls switch to new feasibility-only phase	0
bar_watchdog	toggles watchdog heuristic for barrier algorithms	0

5.27.4.2 General options

Option	Description	Default
act_qpalg	controls choice of algorithm used for QP subproblems when in active-set mode	0
algorithm	controls which algorithm to use	0
blasoption	specifies the BLAS/LAPACK function library to use for basic vector and matrix computations	1
datacheck	toggles KNITRO check for structural errors in problem input	0
delta	initial trust region radius scaling factor	1e-0
feastol	relative feasibility error tolerance	1e-6
feastolabs	absolute feasibility error tolerance	1.0e-3
fstopval	custom stopping condition on objective value	none
ftol	control termination based on successive small objective changes	1e-15
ftol_iters	control termination based on successive small objective changes	5
gradopt	controls gradient computation	1
hessopt	controls Hessian computation	1
honorbnds	maintain feasibility of intermediate iterates w.r.t. variable bounds	0
infeastol	controls relative tolerance for declaring a model infeasible	1e-8
linsolver	controls which linear system solver to use	0
linsolver_ooc	controls out-of-core behavior for MKL PARDISO	0
lmsize	controls number of limited-memory pairs stored for quasi-Newton BFGS	10
maxcgit	limit on inner CG iterations per minor iteration	0
maxfevals	controls the maximum number of function evaluations before termination	unlimited
maxit	major iteration limit	0
maxtime_cpu	CPU time limit	1e8
maxtime_real	real or wall-clock time limit	1e8
objrange	parameter used in unboundedness check	1e20

Option	Description	Default
option_file	additional option file name - read only by KNITRO solver lib	
opttol	relative optimality error tolerance	1e-6
opttolabs	absolute optimality error tolerance	1.0e-3
outlev	controls the level of output	2
output_time	print output on where time is used	0
par_blasnumthreads	number of threads to use for BLAS operations	1
par_lsnumthreads	number of threads to use for PARDISO linear system solver	1
pivot	initial pivot threshold used in the factorization routine	1e-8
presolve	controls presolve level	1
presolve_tol	controls presolver tolerance	1e-6
reform	allow objective reformulation	1
scale	toggles problem scaling	1
soc	toggles the second order correction option	1
threads	default thread count	1
xtol	tolerance for termination on a small stepsize	1e-15

5.27.4.3 Multi-algorithm options

Option	Description	Default
ma_maxtime_cpu	cumulative CPU time limit for multi-algorithm method	1e8
ma_maxtime_real	cumulative real or wall-clock time limit for multi-algorithm method	1e8
ma_terminate	condition for terminating the multi-algorithm method	1

5.27.4.4 MIP options

Option	Description	Default
mip_branchrule	branching rule to use for MIP B&B	0
mip_gub_branch	toggles branching on generalized upper bounds	0
mip_heuristic	MIP heuristic to use in searching for an initial integer feasible point	0
mip_heuristic_maxit	maximum iterations to allow the MIP heuristic	100
mip_implications	toggles addition of constraints derived from logical implications	1
mip_integer_tol	integrality tolerance	1e-8
mip_integral_gap_abs	absolute stopping tolerance for MIP	1e-6
mip_integral_gap_rel	relative stopping tolerance for MIP	1e-6

Option	Description	Default
mip_knapsack	knapsack cut generation control	1
mip_lpalg	algorithm to use for LP subproblems	0
mip_maxnodes	maximum number of nodes to explore: 0=no limit	100000
mip_maxsolves	maximum number of subproblem solves: 0=no limit	200000
mip_maxtime_cpu	cumulative CPU time limit for MIP	1e8
mip_maxtime_real	cumulative real or wall-clock time limit for MIP	1e8
mip_method	specify MIP method to use	0
mip_nodealg	algorithm to use for MIP B&B subproblems	0
mip_outinterval	node printing interval for MIP	10
mip_outlevel	how much MIP information to print	1
mip_pseudoinit	pseudocost initialization method control	0
mip_relaxable	specifies whether integer variables are relaxable	1
mip_rootalg	algorithm to use for the root node solve	0
mip_rounding	MIP rounding rule to apply	0
mip_selectrule	selection rule for the next node in the B&B tree	0
mip_strong_candlim	max candidates to explore in strong branching	10
mip_strong_level	max levels on which to perform strong branching	10
mip_strong_maxit	max iterations to allow for strong branching	1000
mip_terminate	condition for terminating the MIP algorithm	0

5.27.4.5 Multi-start options

Option	Description	Default
ms_deterministic	allow for deterministic parallel MS if ms_terminate=0	1
ms_enable	toggles multi-start method	0
ms_maxbndrange	maximum range to vary unbounded x when generating start points	1e3
ms_maxsolves	maximum number of start points to try during multi-start	auto
ms_maxtime_cpu	cumulative CPU time limit for multi-start	1e8
